But, in the writer's judgment these matters, while curious and interesting, have no appreciable bearing on the current important questions of atmospheric mechanics. There seem to be many widespread delusions and mistakes in regard to these problems, analogous to the popular errors in regard to astrology, and it is hardly necessary to do more than allude to them here. The leading meteorologists have relegated such questions to the care of theoretical astronomers and physicists until our knowledge is more firmly established. Undoubtedly the earth does come under other influences than that of the radiation from the sun; but in the present stage of dynamic meteorology we consider only this latter, and, assuming it to be constant as regards quantity and quality, we find the variable selective absorptions and reflections within our own atmosphere, and its complex internal mechanism afford us a bewildering maze of problems such that so long as these are unsolved it would be folly to spend time on those.

V.—METEOROLOGICAL ORGANIZATIONS

During the latter half of the 19th century the prosecution of work in meteorology gradually passed out of the hands of individuals into the control of large national organizations. This was the natural result of the discovery that, by the spread of the electric telegraph and ocean cables, it had become possible to compile daily weather-maps for large portions of the globe and make predictions of the weather and the storms for a day or two in advance, of sufficient accuracy to be of the greatest importance to the material interests of civilized nations. The development of wireless telegraphy since 1900 has even made it possible for isolated ships at sea to exchange weather telegrams, compile daily maps and study surrounding storms. One by one every civilized nation has established either a weather bureau or a meteorological office, or a bureau of hydrography and marine meteorology, or an elaborate establishment for aerial explorations according as its special interests demanded. These governmental bureaus usually pursue both climatology and theoretical meteorology in addition to their daily practical work of telegraphy, forecasting, and publication of charts. Although, of course, in most cases, the so-called practical work absorbs the greater part of the labour and the funds, yet everywhere it is recognized that research and the development of a correct theory of the motions of the atmosphere are essential to any important progress in the art of forecasting. Among other important general works in which the official weather bureaus have united, we may enumerate the International Meteorological Congresses, of which the first was held in 1853 at Brussels, the second in 1873 at Vienna, and others more frequently since that date; the establishment of an International Committee, to which questions of general interest are referred; the organization of a systematic exploration of the polar regions in the years 1882 and 1883; the general extension of the meteorological services to include terrestrial magnetism as an essential part of the physics of the globe; the systematic exploration of the upper atmosphere by means of kites and balloons; and the universal co-operation with the U.S. Weather Bureau in the contribution of simultaneous data for its international bulletin and its daily map of the whole northern hemisphere. The hydrographic offices and marine bureaus of the principal commercial nations have united so far as practicable in the daily charting of the weather, but have especially developed the study of the climatology of the ocean, not only along the lines laid down by Maury and the Brussels Conference of 1853, but also with particular reference to the tracks of storm centres and the laws of storms on the ocean. The condition of these governmental organizations was discussed in the annual address of the Hon. F. Campbell Bayard, delivered before the Royal Meteorological Society of London in January 1899, and in the text accompanying Bartholomew's *Physical Atlas*, vol. iii.

The development of meteorology, in both its scientific and its practical aspects, is intimately dependent upon the progress of our knowledge of physics, and its study offers innumerable problems that can be solved only by proper combinations of mathematical theory and laboratory experimentation. The professors in colleges and universities who have hitherto lectured on this subject have not failed to develop some features of dynamic meteorology, although most of their attention has been given to climatology. In fact, many of them have been engrossed in the study of general problems in molecular physics, and could give meteorology only a small part of their attention. The early textbooks on meteorology were frequently mere chapters or sections of general treatises on physics or chemistry. The few prominent early cases of university professorships devoted to meteorology are those of the eminent Professor Heinrich Wilhelm Dove at Berlin, Professor Adolphe Quetelet at Brussels and Professor Ludwig Friedrich Kaemtz at Halle and Dorpat. In modern times we may point to Professor Wilhelm von Bezold and George Hellmann at Berlin, Professor Julius Hann at Vienna and Gratz, Professor Josef Maria Pernter at Linz and Vienna, Professor Alexander Woeikof at St Petersburg, Professors Hugo Hildebrand-Hildebrandsson at Upsala, Henrik Mohn at Christiania, Elias Loomis at New Haven, Connecticut, W. M. Davis and R. de C. Ward at Cambridge, Massachusetts, Alfred Angot and Marcel Brillouin at Paris, Hugo Hergesell at Strassburg, Arthur Schuster at Manchester, Peter Polis at Bonn, and Richard Börnstein at the School of Agriculture in Berlin. With these exceptions the great universities of the world have as yet given but little special encouragement to meteorology; it has even been stated that there is no great demand for higher education on the subject. On the other hand, the existence of thousands of voluntary observers, the profound interest in the weather actually taken by every individual, and the numerous schemes for utilizing our very limited knowledge of the subject through the activities of the large weather bureaus of the world demonstrate that there is a demand for knowledge perhaps even higher than the universities can offer. It would be very creditable to a nation or to a wealthy patron of science if there should be established meteorological laboratories in connexion with important universities, at which not only instruction but especially investigation might be pursued, as is done at the magnificent astronomical observatories that are so numerous throughout the world. Every atmospheric phenomenon can be materially elucidated by exact laboratory experiments and measurements, theory can be confronted with facts; and the student can become an original investigator in meteorology.

The great difficulties inherent to meteorology should stimulate the devotion of the highest talent to the progress of this branch of science. The practical value of weather predictions justifies the expenditure of money and labour in order to improve them in every detail.

BIBLIOGRAPHY.—Those who desire recent additions to our knowledge should consult first Hann's *Lehrbuch der Meteorologie* (2nd ed., Leipzig, 1906) as being a systematic encyclopaedia. Of equal importance is the *Meteorologische Zeitschrift* (Berlin and Vienna, 1866 to date). The *Atlas of Meteorology* (Bartholomew, 1900), the *Quarterly Journal of the Royal Meteorological Society* (London) and the *Monthly Weather Review* (Washington) are the works most convenient to English readers and abound with references to current literature. The *Physical Review Science Abstracts* and the *Fortschritte der Physik* contain short notices of all important memoirs and will serve to direct the student's attention toward any special topic that may interest him. (C. A.)

METER, ELECTRIC. In the public supply of electric energy for lighting and power it is necessary to provide for the measurement of the electric energy or quantity by devices which are called electric meters. Those in use may be classified in several ways: (i) according to the kind of electric supply they are fitted to measure, *e.g.* whether continuous current or alternating current, and if the latter, whether monophase or polyphase; (ii) according to whether they record intermittently or continuously; (iii) according to the principle of their action whether mechanical or electrolytic; (iv) according to the nature of the measurement, whether quantity or energy meters. The last subdivision is fundamental. Meters intended to measure electric energy (which is really the subject of the sale and purchase) are called *joule meters*, or generally *watt-hour meters*. Meters intended to measure electric quantity are called *coulomb meters* and also *ampere-hour meters*; they are employed for the measurement of public electric supply on the assumption that the electromotive force or pressure is constant. Most of the practical meters in use at the present time may be classified under the following five heads: electrolytic meters, motor meters, clock meters, intermittent registering meters and induction meters.

Electrolytic Meters are exclusively ampere-hour meters, measuring electric quantity directly and electric energy only indirectly, on the assumption that the pressure of the supply is constant. The first electrolytic house meter in connexion with public electric supply was described by St. George Lane-Fox. He was followed by F. J. Sprague and T. A. Edison, the last-named inventor elaborating a type of meter which he employed in connexion with his system of electric lighting in its early days. The Edison electric meter, like those of Sprague and Lane-Fox, was based upon the principle that when an electric current flows through an electrolyte, such as sulphate of copper or sulphate of zinc, the electrodes being plates of copper or zinc, metal is dissolved off one plate (the anode) and deposited on the other plate (the cathode). It consisted of a glass vessel, containing a solution of sulphate of zinc, in which were placed two plates of pure amalgamated zinc. These plates were connected by means of a german-silver shunt, their size and the distance between them being so adjusted that about $\frac{1}{1000}$ part of the current passing through the meter travelled through the electrolytic cell and $\frac{999}{1000}$ of the current passed through the shunt. Before being placed in the cells the zinc plates were weighed. The shunted voltameter was then inserted in series with the electric supply mains leading to the house or building taking electric energy, and the current which passed dissolved the zinc from one plate and deposited it upon the other, so that after a certain interval of time had elapsed the altered weight of the plates enabled the quantity of electricity to be determined from the known fact that an electric current of one ampere, flowing for one hour, removes 1·2133 grammes of zinc from a solution of sulphate of zinc. Hence the quantity in ampere-hours passing through the electrolytic cell being known and the fraction of the whole quantity taken by the cell being known, the quantity supplied to the house was determined. To prevent temperature from affecting the shunt ratio, Edison joined in series with the electrolytic cell a copper coil the resistance of which increased with a rise of temperature by the same amount that the electrolyte decreased. Owing to the cost and trouble of weighing a large number of zinc plates, this type of meter fell into disuse.

A more modern type of electrolytic meter is that due to C. O. Bastian.[1] The whole current supplied to the house flows through an electrolytic cell consisting of a glass tube containing two platinum electrodes; the electrolyte is dilute sulphuric acid covered with a thin layer of oil to prevent evaporation. As the current flows it decomposes the liquid and liberates oxygen and hydrogen gases, which escape. The quantity of electricity which is passed is estimated by the diminution in the volume of the liquid. A third electrolytic meter of the shunted voltameter type is that of A. Wright. In this meter the electrolyte is a solution of mercurous nitrate which is completely enclosed in a glass tube of a particular form, having a mercury anode and a platinum or carbon cathode. The current is determined by measuring the volume of the mercury delivered at the cathode. In the Long-Schattner electrolytic meter a solution of sulphate of copper is electrolyzed.

Motor Meters.—Amongst motor meters one well-known type belonging to the ampere-hour species is that of S. Z. Ferranti, who introduced it in 1883. It consists of an electromagnet within the iron core of which is a flat disk-like cavity containing mercury, the sides of the cavity being stamped with grooves. The thin disk of mercury is therefore traversed perpendicularly by lines of magnetic force when the magnet is excited. The current to be measured is passed through the coils of the electromagnet, then enters the mercury disk at the centre, flows through it radially in all directions, and emerges at the periphery. The mass of mercury is thus set in motion owing to the tendency of a conductor conveying an electric current to move transversely across lines of magnetic force; it becomes in fact the armature of a simple form of dynamo, and rotates with a speed which increases with the strength of the current. The roughness of the surface of the cavity serves to retard it. The rotation of the mercury is detected and measured by means of a small vane of platinum wire immersed in it, the shaft of this vane being connected by an endless screw with a counting mechanism. The core of the electromagnet is worked at a point far below magnetic saturation (see MAGNETISM); hence the field is nearly proportional to the square of the current, and the resistance offered to the rotating mercury by the friction against the sides of the cavity is nearly proportional to the square of the speed. It follows that the number of the revolutions the mercury makes in a given time is proportional to the quantity of electricity which is passed through the meter. In order to overcome the friction of the counting train, Ferranti ingeniously gave to the core of the electromagnet a certain amount of permanent magnetism. Another well-known motor meter, working on a somewhat similar principle, is that of Chamberlain and Hookham. In its improved form this meter consists of a single horseshoe permanent magnet formed of tungsten-steel having a strong and constant field. Two air-gaps are made in this field parallel to each other. In one of these a copper disk, called the brake disk, revolves, and in the other a copper armature disk. The latter is slit radially, and the magnetic field is so arranged that it perforates each half of the disk in opposite directions. The armature is immersed in a shallow vessel filled with mercury, which is insulated from the vessel and the armature, except at the ends of the copper strips. The current to be measured passes transversely across the disk and causes it to revolve in the magnetic field; at the same time the copper brake, geared on the same shaft, revolves in the field and has local or eddy currents produced in it which retard its action. The principle of the meter is to make the breaking and driving action so strong that the friction of the train becomes immaterial in comparison. This meter is an ampere-hour meter and applicable only to continuous current circuits. Another form of motor meter which is much used is that of Elihu Thomson. It takes the form of a small dynamo having an armature and field magnets without any iron core. The armature carries on its shaft a commutator made of silver slips, and the current is fed into the armature by means of brushes of silver wire. The current to be measured passes through the fixed field-coils, whilst through the armature passes a shunt current obtained by connecting the brushes across the supply mains through a constant resistance. The driving force is balanced against a retarding force produced by the rotation of a copper disk fixed on the armature shaft, which rotates between the poles of a permanent magnet. Induced or eddy currents are thus created in the copper disk, and the reaction of these against the magnetic field offers a resistance to the rotation of the disk. Hence when a current is passed through the meter, the armature rotates and increases its speed until the driving force is balanced against the retarding force due to the eddy currents in the copper brake disk. In these circumstances the number of rotations made by the armature in a given time is proportional to the product of the strength of the current flowing through the armature and that flowing through the field-coils, the former being the current to be measured. Hence the meter is a watt-hour meter and measures electric energy. In order to overcome the friction of the train the field-coils are wound with an auxiliary shunt coil which supplies a driving force sufficient to overcome the friction of the counting train. This last is geared to the shaft of the armature by an endless screw, and the number of revolutions of the armature is reckoned by the counting-dials, which are so arranged as to indicate the consumption in Board-of-Trade units (1 Board-of-Trade unit = 1000 watt-hours). A modification of the above meter with some mechanical improvements has been devised by S. Evershed.[2]

Clock Meters.—Among clock meters the best known is that of H. Aron, which is based upon a principle described by W. E. Ayrton and J. Perry in 1882. It can be constructed to be either an ampere-hour meter or a watt-hour meter, but is usually the latter. Its principle is as follows: Suppose there are two pendulum clocks, one having an ordinary pendulum and the other having a pendulum consisting of a fine coil of wire through which a current is passed proportional to the potential difference of the supply mains—in other words, a shunt current. Below this pendulum let there be placed another coil through which passes the current to be measured; then when currents pass through these coils the pendulum of the second clock will be either accelerated or retarded relatively to the other clock, since the action of gravity is supplemented by that of an electric attraction or repulsion between the coils. Hence the second clock will gain or lose on the other. The two clock motions may be geared to a single counting mechanism which records the difference in the rates of going of the two clocks. If the difference of the number of oscillations made by the two pendulums in a given time is small compared to the number made by either of them separately, then it is easy to show that the power given to the circuit is measured by the gain or loss of one clock over the other in a given time, and can therefore be indicated on a counting mechanism or registering dials. By the use of a permanent magnet instead of a shunt coil as the bob of one pendulum, the meter can be made up as an ampere-hour meter. In this form it has the advantage that it can be used for either continuous or alternating currents.

In *Intermittent Registering Meters* some form of ampere-meter or watt-meter registers the current or power passing into the house; and a clock motion electrically driven is made to take readings of the ampere-meter or watt-meter at definite intervals—say, every five minutes—and to add up these readings upon a set of registered dials. The arrangement therefore integrates the ampere-hours or watt-hours. These meters, of which one well-known form is that of Johnson and Phillips, have the disadvantage of being unsuited for the measurement of electric supply in those cases in which it is irregular or intermittent—as in a theatre or hotel.

Induction Meters are applicable only in the case of alternating current supply. One of the most widely used forms is the Westinghouse-Shallenberger. It consists of a disk of aluminium, the axis of which is geared to a counting mechanism and which runs between the poles of permanent magnets that create eddy currents in it and therefore exert a retarding force. In proximity to the upper side of the disk is placed a coil of wire having an iron core, which is a shunt coil, the ends of the coil being connected to the terminals of the supply mains. Under the disk are two other coils which are placed in series with the supply. When these last coils are traversed by an alternating current they induce local or eddy currents in the disk. The current in the shunt coil lags 90 degrees behind the impressed electromotive force of the circuit to be measured; hence if the main current is in step with the potential difference of the terminals of the supply mains, which is the case when the supply is given wholly to electric lamps, then the field due to the main coil differs from that due to the shunt coil by 90 degrees. Since the eddy currents induced in the disk are 90 degrees in phase behind the inducing field, the eddy currents produced by the main coil are in step with the magnetic field due to the shunt coil, and hence the disk is driven round by the revolution due to the action of the shunt coil upon the induced currents in the disk. Hence the disk will be accelerated until the driving force is balanced by the retarding force due to the induced currents created in the disk by the permanent magnets. When this is the case, the number of revolutions of the meter in a given time is a measure of the watt-hours or energy which is passed through the meter. The counting mechanism and dials may be so arranged as to indicate this energy directly in watt-hours. The meter is made up also in a form suitable for use with two or three fixed electric currents. (See ELECTROKINETICS.)

Requirements of a good House Meter.—A gas meter which has an error of more than 2% in favour of the seller or 3% in favour of the customer is not passed for use. An electricity meter should therefore have approximately the same accuracy. As a matter of fact, it is difficult to rely upon most electric meters to register correctly to less than 4% even between quarter-load and full load. Out of nearly 700 current motor meters of various makes tested at Munich in 1902, only 319 had an error of less than 4%, whilst 259 had errors varying from 4½ to 10%. If possible, however, the departures from absolute accuracy should not be more than 2% at quarter-load, nor more than 3% at a full load. The accuracy of a meter is tested by drawing calibration curves showing the percentage departure from absolute accuracy in its reading for various decimal fractions of full load. Such a test is made by determining with an accurate ammeter or watt-meter the current or power supplied to a circuit for a period measured by a good clock and comparing with this the actual reading of the meter during the same time. A common source of trouble is the short circuiting of the shunt coils owing to the shellaced cotton covering of the wire becoming moist.

[2] See *Journ. Inst. Elec. Eng. Lond.* (1899), 29, 743.

A good meter should start with a current which is not more than 2% of its full load current. With a supply pressure of 200 volts a 5 c.p. carbon filament lamp takes only 0·1 ampere; hence unless a meter will begin to register with $\frac{1}{10}$ ampere it will fail to record the current consumed by a single small incandescent lamp. In a large supply system such failure would mean a serious loss of revenue. The resistance of the meter coils causes a fall in voltage down the series coil which reduces the supply pressure to the consumer. On the other hand the resistance of the shunt coil absorbs energy which generally varies from 1 to 3 watts and is a loss either to the consumer or to the supply company, according to the manner in which the shunt coil is connected. In those meters which are compounded—that is, have a shunt coil wound on the field magnets to compensate for the friction of the train—it is important to notice whether the meter will operate or continue operating when there is no current in the series coil, since a meter which "runs on the shunt" runs up a debt against the consumer for which it gives no corresponding advantage.

Generally speaking, the price of the meter is a subordinate consideration. Since the revenue-earning power of a supply station depends entirely upon its meters, inaccuracy in meter record is a serious matter. The cost of measuring current by the aid of a meter is made up of three parts: (1) the prime cost of the meter, which varies from £2 to £6 for an ordinary 25-light house electric meter; (2) the capital value of the energy absorbed in it, which if the cost of the energy is taken at 2d. per Board-of-Trade unit, with interest and depreciation at 6%, may amount to £10 per customer; and (3) the annual working costs for repairs and also the wages of the staff of meter men, who take the required monthly or quarterly readings. In the case of small and irregular consumers, such as the inhabitants of model dwellings and flats inhabited chiefly by working-class tenants, coin-in-the-slot meters are much employed. The customer cannot obtain current for electric lighting until he has placed in a slit a certain coin—say, a shilling—entitling him to a certain number of Board-of-Trade units—say, to 2 or 4, as the case may be. In the Long-Schattner electrolytic meter, the insertion of the coin depresses a copper plate or plates into an electrolytic cell containing a solution of sulphate of copper; the passage of the current dissolves the copper off one of the plates, the loss in weight being determined by the quantity of the electricity passed. As soon as the plate has lost a certain amount of weight corresponding to the value of the electric energy represented by the coin, the plate rises out of the liquid and cuts off the current.

(J. A. F.)

METHODISM, a term[1] denoting the religious organizations which trace their origin to the evangelistic teaching of John Wesley. The name "Methodist" was given in derision to those Oxford students who in company with the Wesleys used to meet together for spiritual fellowship; and later on when John Wesley had organized his followers into "societies" the name was applied to them in the same spirit. It was however accepted by him, and in official documents he usually styles them "the people called Methodists." The fact that standards of Methodist doctrine are laid down as consisting of "Mr Wesley's Notes on the New Testament and the 1st Series of his Sermons" (fifty-three in number), might seem to indicate a departure from existing systems, but it was not so. He fully accepted the recognized teaching of the Church of England, and publicly appealed to the Prayer Book and the Thirty-nine Articles in justification of the doctrines he preached. Methodism began in a revival of personal religion, and it professed to have but one aim, viz. "to spread Scriptural holiness over the land." Its doctrines were in no sense new. It was the zeal with which they were taught, the clear distinction which they drew between the profession of godliness and the enjoyment of its power—added to the emphasis they laid upon the immediate influence of the Holy Spirit on the consciousness of the Christian—which attracted attention, gave them distinction, and even aroused ridicule and opposition. Wesley and his helpers, finding the Anglican churches closed against them, took to preaching in the open air; and this method is still followed, more or less, in the aggressive evangelistic work of all the Methodist Churches. As followers rapidly increased they were compelled to hold their own Sunday services, and this naturally led them to appoint as preachers godly laymen possessing the gift of exhortation. These followed their ordinary avocations on week-days, but on Sundays preached to congregations in their own immediate neighbourhood, and hence were called *local preachers* as distinguished from *travelling preachers*. The extent to which the employment of the local preacher is characteristic of Methodism may be seen from the fact that in the United Kingdom while there are only about 5000 Methodist ministers, there are more than 18,000 congregations; some 13,000 congregations, chiefly in the villages, are dependent on local preachers.

In the organization adopted to foster spiritual life the very characteristic "Class-meetings for Christian fellowship" take a prominent place. Membership in the church depends solely upon being enrolled as a member of one of these meetings for Christian fellowship, and thus placing oneself under pastoral oversight.

The *Wesleyan Methodists* now represent the original body as founded by John Wesley in Great Britain and Ireland; but in America those who looked upon him as their founder adopted the episcopal mode of Church government after the War of Independence, and have since that time been known as *Episcopal Methodists* (see below). It should be noted that the *Welsh Calvinistic Methodists* are only slightly connected with the original body. They were indirectly the outcome of the evangelistic efforts of Howell Harris and Rowlands. Their work received the sympathy of Wesley and liberal financial help from the Countess of Huntingdon (see CALVINISTIC METHODISTS). For a time Whitefield was leader, and we find a reference to the "Whitefieldian and Wesleyan Methodists" in the Supplement to the *Gentleman's Magazine* for 1747, p. 619. The theological views of these teachers proved quite incompatible with the Arminianism of Wesley, and a definite breach between them and him took place in 1770. The *Welsh Calvinistic Methodists* are now a branch of the Presbyterian Church. Other divisions have been formed at various times by secessions from the Wesleyan Methodists (see separate articles). They are: Methodist New Connexion (founded 1797–1798); Bible Christians (1815); United Methodist Free Churches[2] (about 1836); Primitive Methodists (founded 1807–1810); Independent Methodist Churches (about 1806); Wesleyan Reform Union (1850, reorganized 1859). These bodies have separated solely on matters of Church government and not on points of doctrine. The *Primitive Methodists in Ireland* were a small body who in 1817 seceded because they wished to maintain that close connexion with the Church of England which existed at the time of Wesley's death, but in 1878 they rejoined the parent body. Methodism has always been aggressive, and her children on emigrating have taken with them their evangelistic methods. (For the American branches see below.)

The statistics given in the following table (not including Junior Society Classes) are from the Minutes of the Conference of the Wesleyan Methodist Church for 1909. At the death of Wesley the figures were: 313 preachers, 119 circuits and mission stations, and 76,968 members. In the United States: 97 circuits, 198 preachers and 43,265 members.

In 1837 the membership in Great Britain and Ireland was 318,716; in foreign mission stations, 66,007; in Upper Canada, 14,000; while the American Conferences had charge of 650,678 members. Total for the world: 1,049,401, with 4478 ministers.

Three Oecumenical Conferences have been held—two at City Road, London, in 1881 and 1901, and one at Washington in 1891. The statistics presented at the last showed that the Church during the preceding decade had gained about a million members and three million adherents. At the same time there has been a steadily growing feeling in favour of union. Canada and Australasia led the way, for in these countries the Methodist Church was undivided, and the sentiment was greatly strengthened by the formation in the United Kingdom of the United Methodist Church in 1907.

---

[1] "Methodism" is derived from "method" (Gr. μέθοδος), a rule. A "methodist" is one who follows a "method," the term being applied not only to the Wesleyan body, but earlier to the Amyraldists, and in the 17th century to certain Roman Catholic apologists.

[2] These first three were joined in 1907 under the name of the United Methodist Church.

See *A New History of Methodism*, ed. W. J. Townsend, H. B. Workman, George Eayrs (2 vols., London, 1909). (J. A. V.)

METHODISM IN THE UNITED STATES

There are in the United States sixteen distinct Methodist denominations, all agreeing essentially in doctrine. John Wesley had been conducting his United Societies for more than twenty years before the movement took root in North America.

A.—*Episcopal Methodist Churches.*

Philip Embury (1729–1775), a Wesleyan local preacher, emigrated in 1760 from Limerick to New York. Robert Strawbridge (?–1781), a local preacher and native of Ireland, settled in Maryland. In 1766 Embury was stimulated by his relative, Mrs Barbara Heck, to begin Methodist preaching, and a society was soon formed, which grew rapidly. Embury was reinforced by the arrival of Thomas Webb (1724–1796), an English local preacher and a captain in the British army. Webb and Thomas Taylor, a layman of superior ability, appealed to Wesley to send over missionaries, and the 26th annual British Conference, held in 1768, sent to the society in New York £50 and furnished passage money for two missionaries, Richard Boardman and Joseph Pilmoor (1739–1825). Three years later Francis Asbury was sent over, and was made assistant superintendent. Meanwhile Strawbridge had been preaching with success in Maryland and in Virginia.

These "advance agents" of this spiritual propaganda brought with them Wesley's Arminian Theology. They brought also "the means of grace" on which Wesley placed the greatest stress; such as personal testimony in private and public, class and prayer meetings, watch-nights, love-feasts, the direct and fervent preaching of the Gospel and the singing of Wesleyan hymns, carried on by means of circuits and stations, exhorters, local and travelling preachers, and the organization of local societies with class leaders, stewards and trustees. The intention was to make American Methodism a facsimile of that in England, subject to Wesley and the British Conference—a society and not a Church. Pilmoor and others objected to Asbury's strict discipline, and Wesley, hearing of the disagreement, in 1773 appointed Thomas Rankin (*c.* 1738–1810) superintendent of the entire work of Methodism in America.

The First American Conference.—The first American Conference was held in 1773, and consisted of ten preachers, all of whom were born in England or Ireland. Asbury came to America to remain permanently; but Rankin, unable to identify himself with its people, to take the test oaths required in the Revolution, or to sympathize with the colonies, returned to England, as did all the English preachers except Asbury. By May 1776 there were 24 preachers and 4921 members; but in the first year of the Revolution there was a loss of 7 preachers and nearly 1000 members. The next year saw extensive revivals, in sections removed from the seat of war, which added more than 2600 to the number of members.

The preachers in the South determined upon administration of the sacraments, and a committee was chosen whose members ordained themselves and others. The Northern preachers opposed this step and for several years the Connexion was on the verge of disruption. An agreement was finally made to suspend the administration until Wesley's desires and judgment could be ascertained. He perceived that the society would disintegrate unless effective measures were speedily taken, and, aided by two presbyters of the Church of England, early in 1784 he ordained Thomas Coke (1747–1814), already a presbyter of that Church, as superintendent. He likewise ordained two of his lay preachers as deacons and elders, to accompany Coke, whom Wesley sent to America as his commissioner to establish, for the Methodist Society, a system of Church government, which should include the administration of Baptism and of the Lord's Supper. Coke was furnished by Wesley with a document setting forth the grounds on which he had taken this step. Wesley also appointed Thomas Coke and Francis Asbury "to be joint superintendents over our brethren in North America." Soon after Coke and his companions arrived they met Asbury and fifteen preachers, and a special conference was called, which opened on the 24th of December 1784, in the suburbs of Baltimore, Maryland. This convention organized itself into a Methodist Episcopal Church, in which the liturgy sent by Wesley should be read, and the sacraments should be administered by superintendents, elders and deacons, these elders and deacons to be ordained by a presbytery using the episcopal form. Coke and Asbury were unanimously elected superintendents, Coke, aided by his clerical companions from England, ordaining Asbury as deacon and elder and formally consecrating him a general superintendent. Several elders were ordained. This convention adopted the first Discipline of the Methodist Episcopal Church. It adopted the existing doctrinal standards, consisting chiefly of Wesley's Sermons and his Notes on the New Testament; also twenty-five of the Articles of Religion of the Church of England, modified so as to eradicate all trace of High Church ritualism, Anglican or Roman, and the distinctive doctrines of Calvinism.

---

[1] Seating accommodation, 2,374,425.

[2] Other preaching-places, 1561.

[3] Sunday and Thursday Schools.

[4] Methodism is also represented in several European countries by Conferences and Missions affiliated to the Methodist Episcopal Church of America, and their membership is included in the figures given above. The 1908 returns are: Bulgaria, 546 members; Denmark, 3771; Finland and St Petersburg, 1367; France, 221; Italy, 3669; North Germany, 12,886; Norway, 6054; South Germany, 11,808; Sweden, 15,430; Switzerland, 9419.

[5] Western Conference only.

The Church thus established began its ecclesiastical career with 18,000 members, 104 travelling preachers, about the same number of local preachers, and more than 200 licensed exhorters. There were 60 chapels and 800 regular preaching places.

The energy of Asbury, and the position of Coke in the Church of England, his wealth, culture, and preaching power, greatly reinforced the efforts of the preachers. The administration of the sacraments brought peace; and many who would not unite with the "Society" asked admission to the Church. Within five years the number of preachers swelled to 227, and the members to 45,949 (white) and 11,682 (coloured).

To bind the whole body the existing method required the concurrence of each Annual Conference with every proposition. This was inconvenient and occasioned much loss of time; therefore a General Conference was established to meet once in four years. The first was held in 1792, and therein arose a sharp conflict. James O'Kelly (1735–1826), a Presiding Elder in control of a large district, proposed that, when the list of appointments was read in the Conference, if any preacher was not pleased with his assignment he might appeal to the Conference. The motion being lost, O'Kelly and several other preachers seceded. The Conference in 1804 limited the power of the Bishops by forbidding them to appoint any pastor for more than two consecutive years in charge of the same church. As all "travelling preachers" were eligible, without election, to seats in General Conferences, widespread dissatisfaction prevailed among the distant Conferences. The era of the steamboat and the railway not having arrived, it was possible for two Annual Conferences, adjacent to the seat of the General Conference, to out-vote all others combined. This led to a demand for the substitution of a delegated General Conference, which was conceded by the Conference of 1808 to take effect four years later. The office then known as the Presiding Eldership had become powerful: Bishops appointed the pastors to churches, Presiding Elders to districts; but it was the purpose of the majority to transfer to the Annual Conferences the power of appointing Presiding Elders. The change, though discussed for many years, has not been accomplished.

Several issues had been settled; but one, that of slavery, had to be faced. The storm burst on the Conference of 1844. Bishop James Osgood Andrew (1794–1871), a native of the South, had, by inheritance and marriage, become a slaveholder. After debates of many days, he was requested "to desist from the exercise of the office of Bishop while this impediment remained." The Southern members declared that the infliction of such a stigma upon Bishop Andrew would make it impossible for them to maintain the influence of Methodism in the South, and a tentative plan of separation was adopted by the Conference by an almost unanimous vote. The result was that the Methodist Episcopal Church was bisected, and when the General Conference of 1848 convened it represented 780 travelling preachers and 532,290 members fewer than it had numbered four years before.

After the Civil War the increase in membership was noteworthy. The quadrennial Conference of 1868 represented 222,687 members more than its predecessor; of this gain 117,326 were in the Southern States. In 1872 lay representatives were admitted, the Constitution having been amended so as to make it legal. It was not, however, an equal representation, for though ministerial Conferences were represented according to their number, in no circumstances could there be more than two lay representatives from one Annual Conference. Not till 1900 were lay and clerical representation equalized. In 1864 the time limit of pastorates was lengthened to three years, and in 1888 to five years. This limit was taken off in 1900, and pastors can be reappointed at the will of the Bishop.

Five women presented credentials as lay delegates in 1888. Their eligibility was questioned; and they were denied admission. For the next four General Conferences the struggle for the admission of women recurred. In 1900–1904 a general revision of the Constitution took place, and the words "lay members" were substituted for "laymen" in that part of the Constitution which deals with the eligibility of delegates to the General Conference.

The General Conference has power to make rules and regulations for the Church, subject only to restrictions which protect the Standards of Doctrine, the General Rules, the disposition of the property of the Book Concern and its income, the income of the Chartered Fund, and the right of ministers to trial before a jury of their peers, an appeal, and similar rights of the laity. By a two-thirds vote of a General Conference, and two-thirds votes of the members of the Annual Conference, and of the members of the Lay Electoral Conferences, present and voting, what is said in these "Restrictive Rules" can be altered or repealed, except that which deals with the Articles of Religion and "the present existing and established Standards of Doctrine." In the Annual Conferences the Bishop is the sole interpreter of law, subject to appeal to the General Conference. When presiding in the General Conference, a Bishop has no authority to decide questions of law, but may decide questions of order subject to an appeal to the body. The district superintendent visits each charge several times annually, presiding in the Quarterly Conference, the highest local authority in the Church, and he is expected to conserve the unity of the denomination and a regard for laws enacted by the supreme body. In the absence of a Bishop the district superintendent represents him, and may transfer any ministers within the bounds of his district.

Connexional Institutions.—The Book Concern, established in 1789, publishes the necessary devotional books of the Church, such as hymnal, discipline, theological works, religious experience, and numerous magazines and papers.

The Board of Foreign Missions carries on extensive operations in China, Japan, Korea, India and Malaysia, Italy, South America and Mexico. It assists the Methodist Churches organized in Norway, Sweden, Denmark, Finland, Germany and Switzerland, and has recently established missions in Russia and France.

The Board of Home Missions and Church Extension supplies the foreign peoples domiciled in the United States with ministers of their own tongue. It assists all English-speaking churches in need of help, and secures, by gifts and time loans, the erection of churches wherever needed. Invaluable coadjutors of these Boards are the Women's Foreign Missionary and the Women's Home Missionary societies.

The Board of Education, with the aid of a University Senate, assists young people to obtain education, and raises the standard of seminaries, colleges and universities. The Church, in the United States, supports 54 colleges and universities and 10 theological seminaries. The Freedmen's Aid Society is devoted to the educational needs of the negro race in the United States, in which work it has been very successful.

The Sunday School Union, Epworth League, Methodist Brotherhood, hospitals, homes for the aged, deaconess homes and children's institutions are maintained by an increasing army of workers.

The whole number of ministers (exclusive of foreign missions) in 1907, was 17,694; churches, 27,691; communicants, 2,984,261.

The Methodist Episcopal Church South.—After the adjournment of the General Conference of 1844, the representatives of thirteen Conferences covering the states holding slaves appealed to their constituents to determine what should be done to prevent Methodism in the South from being deprived of its influence over the whites and of the privilege, till then fully accorded, of preaching the Gospel and teaching its precepts to slaves. In 1845 a representative Convention was called; this body, with the approval and participation of Bishop Andrew, organized the Methodist Episcopal Church South. At its first General Conference, in 1846, the senior Bishop of the Methodist Episcopal Church, Joshua Soule (1781–1867), offered himself to the Church, which accepted him in his episcopal capacity. William Capers (1790–1855) and Robert Paine (1799–1882) were elected to the Episcopacy. The Church thus founded began with 460,000 members, of which 2972 were Indians, 124,961 coloured, and 1519 travelling ministers.

A difficulty arose on the division of the property of the Book Concerns, which the Methodist Episcopal Church maintained involved a change in the Constitution. A vote to authorize the division failed, and the Methodist Episcopal Church South, hopeless of relief, brought two suits, one against the Book Concern in New York, and the other against the Book Concern in Cincinnati. The former was decided in favour of the Methodist Episcopal Church South, and the latter in favour of the Methodist Episcopal Church. In the latter case an appeal was taken by the Methodist Episcopal Church South to the Supreme Court of the United States, which body unanimously decided that the Methodist Episcopal Church South was an integral part of the Methodist Episcopal Church which owned the Book Concerns, and ordered that the Southern Church should receive a proportionate part of the property of both Book Concerns. The amount ordered by the Court was in due time received.

The membership of the Church in 1860 was more than three-quarters of a million; but the Church was doomed to feel the force of the destructive elements of the Civil War. In April 1862 New Orleans was in possession of the Federal Government, rendering it impossible to hold the General Conference due at that time and place.

At the close of the war the Missionary Society of the Church was $60,000 in debt, the Publishing House practically in ruins, and of the more than 200,000 coloured members in 1860 there remained fewer than 50,000. The Conference of 1866 convened in New Orleans. Radical changes in polity were effected. Attendance upon class meetings, which, from the origin of the Church had been obligatory, was made voluntary, and the rule was repealed which required a probation of six months before admission into full membership. The time limit on the continuation of pastorates was extended from two to four years. The most radical change was the introduction into the General Conference of a number of lay representatives equal to the number of clerical, and the admission into each Annual Conference of four lay delegates for each Presiding Elder's district.

The coloured people, with the consent of the Church, withdrew in 1870, and formed a new Church called the Coloured Methodist Episcopal Church.

The most striking denominational effort in its history was the maintenance of the solvency of the Publishing House, which was seized by the Federal Troops, and used as a United States printing office; with the damage done, and debts incurred in rebuilding, after a fire, interest, &c., the liabilities were $35,000, with debts $125,000 in excess of assets. The concern was declared insolvent; but the necessary funds were forthcoming, and the honour of the Church was maintained.

Education has received unceasing attention. The titles to 175 institutions are held by the Church, and the list of colleges and their character is a credit to the denomination. The most important is Vanderbilt University, at Nashville, Tennessee, founded in 1872, and largely endowed by members of the family whose name it bears. The chief foreign missions are in China, Mexico, Brazil, Japan, Korea and Cuba. Its mission in Japan and the mission of the Methodist Episcopal Church and the Methodist Church of Canada were united in 1907 in a new organization entitled the Methodist Church of Japan. A distinguishing feature of this church is a practical veto power possessed by the bishops, to be exercised when the conference adopts any measure which in their opinion is unconstitutional. They have the right to present written objections and should the General Conference, by two-thirds vote adhere to its action, the proposal is sent down to the Annual Conference for ratification; otherwise it is void. Fraternal relations between the two great Episcopal Methodist Churches were fully established in 1876, and have broadened in spirit and scope from that time.

The Methodist Episcopal Church South in 1907 had 6774 ministers, 16,156 churches and 1,631,379 communicants.

The African Methodist Episcopal Church.—This body originated in strained relations between the white and coloured Methodists of Philadelphia, Pennsylvania, the result of which was, that the coloured people organized themselves, in 1816, into an independent body. They adopted as their standards the doctrines of the Methodist Episcopal Church, and, with a few modifications, its form of government. The Church steadily prospered, but for several years not proportionately in the department of education. Daniel Alexander Payne (1811–1893), who had studied in the Gettysburg Theological Seminary, led a reform, which involved a marked elevation of the qualifications for ministers, and from that time the body has constantly risen in public estimation. One of its peculiarities is that the bishops are members of the General Conference. It sustains Wilberforce University (at Wilberforce, Ohio) and other educational institutions, and has missions in Africa, South America, the West Indies and Hawaii. Notable orators have risen up among its members, who have added greatly to the respect felt for their race and Church. The African Methodist Episcopal Church, the largest Christian denomination consisting wholly of the Negro race, in 1907 comprised 6190 ministers, 5321 churches, and 842,023 communicants.

The African Methodist Episcopal Zion Church.—Some of the coloured people in the city of New York, "feeling themselves oppressed by caste prejudice, and suffering the deprivation of Church privileges permitted to others," organized among themselves, in 1796, and in the year 1800 built a church and named it Zion. For twenty years the Methodist Episcopal Church supplied this church with pastors. Then the members induced three white ministers to ordain as elders three of their brethren, already deacons. Since they had Methodist precedents for such ordination, these proceeded to ordain others, and established churches in Philadelphia and New Hampshire. The elders ordained one of their number a bishop. As late as 1863 the Church had only 92 ministers and 5000 members, but in twelve years it doubled its membership more than five times. In this Church the sexes are equally eligible to all positions. Its educational operations at first were failures, but gradually became successful. Its foreign missions were made a separate department in 1884. This Church had, in 1907, 3871 ministers, 3206 churches and 573,107 communicants.

The Coloured Methodist Episcopal Church.—In 1866 the General Conference of the Methodist Episcopal Church South authorized the bishops to organize its coloured members into an independent ecclesiastical body, if it should appear that they desired it. The bishops formed a number of Annual Conferences, consisting wholly of coloured preachers, and in 1870 these Conferences requested the appointment of five commissioners of the Caucasian part of the Church to meet five of their own number to create an independent Church. Two Bishops of the Methodist Episcopal Church South presided, and ordained to the Episcopacy two coloured elders, selected by the eight coloured conferences. The coloured people by vote named the organization the Coloured Methodist Episcopal Church.

The Union American Methodist Episcopal Church agrees in doctrines and usages with other Methodist bodies. It is divided into Conferences and elects its Bishops for life. It had in 1907, 18,500 members, 138 ministers and 255 churches.

B.—*Non-Episcopal Methodist Churches.*

The Methodist Protestant Church.—In 1821 ministers and laymen of the Methodist Episcopal Church began to criticize its polity, and when their utterances became aggressive the adherents to the regular order replied with equal vigour. During the General Conference of 1824, held in Baltimore, a Convention of "Reformers" met, and established a periodical entitled *The Mutual Rights of the Ministers and Members of the Methodist Episcopal Church*, and made arrangements to organize Union Societies. Travelling and local ministers and laymen were expelled for schism and spreading incendiary publications. Prior to the Conference those expelled, and their sympathizers, formed themselves into a society named "Associate Methodist Reformers." These sent memorials to the General Conference of 1828, and issued addresses to the public. After a powerful and painful discussion, the appeals of the expelled members of

Conferences were rejected. The controversy centred upon lay representation, the episcopacy and the presiding eldership.

A General Convention was held on the 2nd of November 1830, a Constitution was adopted, and a new organization was established, styled the Methodist Protestant Church. Within eight years it had accumulated 50,000 members, the majority of whom were in the South and bordering states. The Methodist Protestant Church has a presbyterial form of government, the powers being in the Conference. There is no episcopal office or General Superintendent; each Annual Conference elects its own chairman. Its General Conference meets once in four years. Ministers and laymen equal in number are elected by the Annual Conferences, in a ratio of one delegate for 1000 members. The General Conference of the Methodist Episcopal Church of 1908 sent delegates to the Conference of the Methodist Protestant Church, making overtures toward an organic union, but formal negotiations have not been instituted. This Church had, in 1907, 1551 ministers, 2242 churches and 183,894 communicants.

The Wesleyan Methodist Connection or Church of America.—In the Methodist Episcopal Church slavery was always a cause of contention. In 1842 certain Methodist abolitionists conferred as to the wisdom of seceding. Among the leaders were Orange Scott (1800–1847), Jotham Horton and Le Roy Sunderland (1802–1885) and in a paper, which they had established, known as *The True Wesleyan*, they announced their withdrawal from the Church, and issued a call for a convention of all like-minded, which met on the 31st of May 1843, at Utica, New York, and founded the Wesleyan Methodist Connection or Church of America. The enterprise started with 6000 laymen and 22 travelling ministers of the Methodist Episcopal Church, and nearly as many more from the Methodist Protestant Church and other small bodies of Methodist antecedents. Its General Conference has an equal number of ministers and laymen. In less than eighteen months this body had gained in members 250%; but as the Methodist Episcopal Church had purged itself from slavery in 1844, and slavery itself was abolished in 1862, a large number of ministers and thousands of communicants, connected with this body, returned to the Methodist Episcopal Church. It had in 1907 539 ministers, 609 churches and 18,587 communicants.

The Congregational Methodists originated in Georgia in 1852; but in polity they are not strictly Congregational. Appeals from the decision of the Lower Church may be taken to a District Conference, thence to the State Conference, and ultimately to the General Conference. This Church had, in 1907, chiefly in Southern states, 24,000 members, 415 ministers and 425 churches.

The Free Methodist Church.—This body was organized in August 1860, and was the result of ten years of agitation. A number of ministers and members within the bounds of the Genesee Conference, in Western New York, in 1850, began to deplore and denounce the decline of spirituality in the Methodist Episcopal Church. The Rev. B. T. Roberts, the ablest among them, was reprimanded by the Bishop presiding in the Annual Conference, and next year he was expelled. Similar proceedings were taken against others, who appealed to the General Conference of 1860, but their expulsion was confirmed. It was the purpose of the founders to conserve the usage and the spirit of primitive Methodism. The government of the Church is simple, in all but the Episcopacy and its adjuncts resembling that of the Church whence it sprang. The Free Methodist Church had, in 1907, 1032 ministers, 1106 churches, and 31,376 communicants.

Minor Methodist Churches.—The Primitive Methodist Church, as it exists in the United States, came from England. In 1907 it reported 7013 communicants. *The Independent Methodists* are composed of congregations in Maryland, Tennessee and the District of Columbia. They had fewer than 3000 members in 1907. *The Evangelist Missionary Church* comprises ministers and members in Ohio, who in 1886 withdrew from the African Methodist Episcopal Zion Church. They had in 1907 about 5000 members. *The New Congregational Methodists* in 1881 withdrew from the Methodist Episcopal Church South, in Georgia. They had 4022 members in 1907. *The African Union Methodist Protestant Church* dates from 1816, and differed from the African Methodist Episcopal Church in opposing itinerancy, "paid ministers," and episcopacy. In 1907 it had 3867 members in eight states. *The Zion Union Apostolic Church* was organized in 1869, in Virginia. It was reported in 1890 to have 2346 communicants, and shows no gain at the present time.

(J. M. Bu.)

METHODIST NEW CONNEXION, a Protestant Nonconformist Church, formed in 1797 by secession from the Wesleyan Methodists, and merged in 1907 into the United Methodist Church (*q.v.*). The secession was led by Alexander Kilham (*q.v.*), and resulted from a dispute regarding the position and rights of the laity, Kilham and his party desiring more power for the members of the Church and less for the ministers. In its conferences ministers and laymen were of equal number, the laymen being chosen by the circuits and in some cases by "guardian representatives" elected for life by conference. Otherwise the doctrines and order of the Connexion were the same as those of the Wesleyans. At the time of the union with the Bible Christians and the United Methodist Free Church in 1907 the Methodist New Connexion had some 250 ministers and 45,000 members.

METHODIUS (*c.* 825–885), the apostle of the Slavs, was a native of Thessalonica, probably by nationality a Graecized Slav. His father's name was Leo, and his family was socially distinguished; Methodius himself had already attained high official rank in the government of Macedonia before he determined to become a monk. His younger brother Constantine (better known as Cyril, the name he adopted at Rome shortly before his death) was a friend of Photius, and had earned the surname "the Philosopher" in Constantinople before he withdrew to monastic life. Constantine about 860 had been sent by the emperor Michael III. to the Khazars, a Tatar people living north-east of the Black Sea, in response to their request for a Christian teacher, but had not remained long among them; after his return to within the limits of the empire, his brother and he worked among the Bulgarians of Thrace and Moesia, baptizing their king Bogoris in 861. About 863, at the invitation of Rastislav, king of "Great Moravia," who desired the Christianization of his subjects, but at the same time that they should be independent of the Germans, the two brothers went to his capital (its site is unknown), and, besides establishing a seminary for the education of priests, successfully occupied themselves in preaching in the vernacular and in diffusing their translations of Scripture lessons and liturgical offices. Some conflict with the German priests, who used the Latin liturgy, led to their visiting Pope Nicholas I., who had just been engaged in his still extant correspondence with the newly converted Bulgarian king; his death (in 867) occurred before their arrival, but they were kindly received by his successor Hadrian II. Constantine died in Rome (in 869), but Methodius, after satisfying the pope of his orthodoxy and obedience, went back to his labours in "Moravia" as archbishop of Syrmia (Sirmium) in Pannonia. His province appears to have been, roughly speaking, co-extensive with the basins of the Raab, Drave and Save, and thus to have included parts of what had previously belonged to the provinces of Salzburg and Passau. In 871 complaints on this account were made at Rome, nominally on behalf of the archbishop of Salzburg, but really in the interests of the German king and his Germanizing ally Swatopluk, Rastislav's successor; they were not, however, immediately successful. In 879, however, Methodius was again summoned to Rome by Pope John VIII., after having declined to give up the practice of celebrating mass in the Slavonic tongue; but, owing to the peculiar delicacy of the relations of Rome with Constantinople, and with the young church of Bulgaria, the pope, contrary to all expectation, ultimately decided in favour of a Slavonic liturgy, and sent Methodius (880) back to his diocese with a suffragan bishop of Neitra, and with a letter of recommendation to Swatopluk. This suffragan, a German named Wiching, unfortunately proved the reverse of helpful to his metropolitan, and through his agency, especially after the death of John VIII. in 882, the closing years of the life of Methodius were embittered by continual ecclesiastical disputes, in the course of which he is said to have laid Swatopluk and his supporters under the ban, and the realm under interdict. The most trustworthy tradition says that Methodius died at Hardisch on the March, on the 6th of April 885. He was buried at Welehrad (probably Stuhlweissenburg).

The Greek Church commemorates St Cyril on February 14 and St Methodius on May 11; in the Roman Church both are commemorated on March 9. Their canonization (by Leo XIII. in 1881) is noteworthy, in view of the fact that Gregory VII. and several other popes condemned them as Arians. After the death of Methodius much of his work was undone; his successor Gosrad, a Slav, was expelled, with all the Slav priests, and the Latin language and liturgy supplanted the vernacular. On the 5th of July 1863 a millennial celebration of the two brother apostles was held by the people of Bohemia and Moravia.

Bonwetsch, *Cyrill und Methodius, die Lehrer der Slaven* (Erlangen, 1885), and art. in Hauck-Herzog's *Realencyk. für prot. Theol.* iv. 384, where the literature is cited; G. F. Maclear, *Conversion of the Slavs* (London, 1879).

METHUEN, BARONY OF. The English title of Baron Methuen of Corsham (Wilts) was created in 1838 for Paul Methuen (1779–1849), who had been a Tory member of parliament for Wilts from 1812 to 1819, and then sat as a Whig for North Wilts from 1833 to 1838. His father, Paul Methuen, was the cousin and heir of the wealthy Sir Paul Methuen (1672–1757), a well-known politician, courtier, diplomatist and patron of art and literature, who was the son of John Methuen (*c.* 1650–1706), Lord Chancellor of Ireland (1697–1703) and ambassador to Portugal. It was the last-named who in 1703 negotiated the famous "Methuen Treaty," which, in return for the admission of English woollens into Portugal, granted differential duties favouring the importation of Portuguese wines into England to the disadvantage of French, and thus displaced the drinking of Burgundy by that of port. He and his son were both buried in Westminster Abbey. The 1st baron was succeeded in the title by his son Frederick Henry Paul Methuen (1818–1891), and the latter by his son Paul, 3rd baron (b. 1845), a distinguished soldier, who became a major-general in 1890, and general officer commanding-in-chief in South Africa in 1907. The 3rd baron joined the Scots Guards in 1864, served in the Ashanti War of 1874 and the Egyptian War of 1882, and commanded Methuen's Horse in Bechuanaland in 1884–85, and the first division of the 1st Army Corps in the South African War of 1899–1902. (See TRANSVAAL.)

METHUSELAH, in the Old Testament, the seventh in descent from Adam, and father of Lamech. According to Genesis v. 21 he lived 969 years (see BIBLE: *Old Testament*, § 5, "Chronology"). The name itself has been much discussed. Holzinger interprets it as "man of the javelin": Hommel prefers "man of Selah," Selah being the Hebraized form of the Babylonian Sarrahu (*i.e.* the god Sin), and identifies it with the Ἀμέμψινος of Berossus. The form Methushael, used by the author of Gen. iv. 18 and by some commentators preferred for Gen. v. 21, is variously explained as meaning "man of El" (Ball), or as a transcription (Sayce) of the Babylonian Mutu-ṣa-ili (possibly, "man of the goddess").

METHVEN, a village and parish of Perthshire, Scotland, 7¾ m. W. by N. of Perth by the Caledonian Railway. Pop. of parish (1901), 1699. Only an aisle remains of the collegiate church founded in 1433 by Walter Stewart, earl of Atholl (d. 1437). One mile east of the village, Methven Castle, dating partly from 1680, occupies a fine situation in a park in which stands the Pepperwell oak, 18 ft. in circumference. At Dronach Haugh near the banks of the Almond, which bounds the parish on the N., the earl of Pembroke defeated Robert Bruce in 1306. At Lynedoch, his estate on the Almond, Thomas Graham (1748–1843), the Peninsular general, afterwards Lord Lynedoch, carried on many experiments in farming and stock-breeding. He formerly owned Balgowan House, about 3 m. south-west of Methven, where many years after his death the proprietor discovered, during certain alterations, the portrait of Lord Lynedoch's wife, the Hon. Mrs Graham (a daughter of the 9th Lord Cathcart), one of Gainsborough's masterpieces, now in the National Gallery in Edinburgh; 4½ m. north-west of Methven, occupying a beautiful position in Glenalmond, is Trinity College, a public school on the English model, the first of its kind in Scotland, founded in 1841 through the efforts of W. E. Gladstone, J. R. Hope-Scott, Dean Ramsay and others, and opened in 1847. In 1851 Charles Wordsworth, the first warden, afterwards bishop of St Andrews, added the chapel. At Tibbermore, or Tippermuir, about 3 m. south-east of Methven, Montrose won the first of a series of battles over the Covenanters on the 1st of September 1644.

METHYL ALCOHOL (CH_3OH), the simplest aliphatic alcohol; an impure form is known in commerce as wood-spirit, being produced in the destructive distillation of wood. The name methyl, from Gr. μέθυ, wine, ὕλη, wood, explains its origin. Discovered by Boyle in 1661, it was first carefully studied by Dumas and Péligot in 1831; its synthesis from its elements (through methane and methyl chloride) was effected by Berthelot in 1858. It is manufactured by distilling wood in iron retorts at about 500° C., when an aqueous distillate, containing methyl alcohol, acetone, acetic acid and methyl acetic ester, is obtained. This is neutralized with lime and redistilled in order to remove the acetic acid. The distillate is treated with anhydrous calcium chloride, the crystalline compound formed with the alcohol being separated and decomposed by redistilling with water. The aqueous product is then dehydrated with potash or lime. To obtain it perfectly pure the crude alcohol is combined with oxalic, benzoic or acetic acid, and the resulting ester separated, purified, and finally decomposed with potash. Methyl alcohol is also obtained in the dry distillation of molasses. The amount of methyl alcohol present in wood spirit is determined by converting it into methyl iodide by acting with phosphorus iodide; and the acetone by converting it into iodoform by boiling with an alkaline solution of iodine in potassium iodide; ethyl alcohol is detected by giving acetylene on heating with concentrated sulphuric acid, methyl alcohol, under the same circumstances, giving methyl ether.

Pure methyl alcohol is a colourless mobile liquid, boiling at

66°–67°, and having a specific gravity of 0·8142 at 0° C. It has a burning taste, and generally a spirituous odour, but when absolutely pure it is said to be odourless. It mixes in all proportions with water, alcohol and ether. Its compound with calcium chloride has the formula $CaCl_2 \cdot 4CH_3 \cdot OH$, and with barium oxide $BaO \cdot 2CH_3OH$. Oxidation gives formaldehyde, formic acid and carbonic acid; chlorine and bromine react, but less readily than with ethyl alcohol. The chief industrial applications are for making denatured alcohol (*q.v.*), and as a solvent, *e.g.* in varnish manufacture; it is also used for a fuel; a purer product is extensively used in the colour and fine chemical industries.

Methyl chloride CH_3Cl, is a gas, boiling at –23°, obtained by chlorinating methane, or better, from methyl alcohol; wood spirit is treated with salt and sulphuric acid, or hydrochloric acid gas conducted into the boiling spirit in the presence of zinc chloride, the evolved gas being washed with potash and dried by sulphuric acid. It is also prepared by heating trimethylamine hydrochloride. Alcohol dissolves 35 volumes and water 4. *Methyl bromide* is a liquid, specific gravity 1·73, boiling point 13°; *methyl iodide* has a specific gravity of 2·19, and boils at 43°.

METICULOUS (through Fr. *méticuleux*, from Lat. *meticulosus*, timid, cautious; *metus*, fear), a term meaning pedantically or excessively careful of details, over-scrupulous, laying too much stress on *minutiae*.

METOCHITA, THEODORE [THEODOROS METOCHITES], a Byzantine author, man of learning and statesman, who flourished during the reign of Andronicus II. Palaeologus (1282–1328). After the deposition of his patron by Andronicus III., Metochita was deprived of his office of great logothete (chancellor) and sent into exile. He was soon recalled, but retired from political life to a convent, where he died in 1332. He was a man of very great learning, only surpassed by Photius and Michael Psellus. His pupil Nicephorus Gregoras, who delivered his funeral oration, calls him a "living library."

Only a few of his numerous works have been preserved. The best known is Ὑπομνηματισμοὶ καὶ σημειώσεις γνωμικαί, *Miscellanea philosophica et historica* (ed. C. G. Müller and T. Kiessling, 1821), containing some 120 essays; for a list of them see Fabricius, *Bibliotheca graeca* (ed. Harles), x. 417; in these he chiefly made use of Synesius. Of his rhetorical pieces two have been published by C. N. Sathas in Μεσαιωνικὴ βιβλιοθήκη (1872), and two poems on religious subjects by M. Treu (1895). The poems, dealing mainly with contemporary and personal matters, are written in hexameter, not in the usual "political" verse. Metochita was also the author of works on philosophical and astronomical subjects.

METONIC CYCLE, in chronology, a period of 19 years during which there are 235 lunations, so called because discovered by Meton. Computation from modern data shows that 235 lunations are 6939 days, 16·5 hours; and 19 solar years, 6939 days, 14·5 hours. The relation between integral numbers of months and years expressed by Meton's rule therefore deviates only two hours from the truth. Since 19 Julian years make 6939 days, 18 hours, the relation errs by only 1·5 hour when the Julian year is taken. Meton was an Athenian astronomer (fl. 432 B.C.).

METONYMY (Gr. *μετωνυμία*, change of name, from *μετά* denoting change, and *ὄνομα*, name), a figure of speech, in which the name of one thing is changed for that of another, to which it is related by association of ideas, as having close relationship to one another. Thus "sceptre," "throne," "crown," are used for royal power or authority, "hearth and home" is used for "country," &c.

"Synecdoche" (Gr. *συνεκδοχή*, from *συνεκδέχεσθαι*, to join in receiving) is a rhetorical figure similar to metonymy, in which the part is used for the whole or vice versa, thus "hands" is used for the members of the crew of a vessel; a regiment of infantry is said to number so many "bayonets," &c.

METOPE (Gr. *μετόπη*, a middle space), a term in architecture for the square recess between the triglyphs in a Doric frieze, which is sometimes filled with sculpture.

METRE (*μετρική*, sc. *τέχνη*, from Gr. *μέτρον*, measure), in prosody, the harmonious and regulated disposition of syllables into verse. Metrical form is distinguished from prose by the uniformity of corresponding lines in relation to the number of syllables and the similarity of final sound (rhyme or assonance), by the repetition of certain letters at regular intervals (in alliterative measure), or merely by the regular succession of ups and downs of intonation. In ancient classic poetry the measure which creates the metrical form consists only of this last quantitative element, which is rhythm.

For the rules and divisions of the various metrical systems, see VERSE. For the restricted use of "metre" as a unit of measurement, see METRIC SYSTEM below.

METRIC SYSTEM (adapted from Gr. *μέτρον*, measure), that system of weights and measures of which the metre is the fundamental unit. The theory of the system is that the metre is a $\frac{1}{10000000}$ part of a quandrant of the earth through Paris; the litre or unit of volume is a cube of $\frac{1}{10}$ metre side; the gramme or unit of weight is (nominally) $\frac{1}{1000}$ of the weight of a litre of water at 4° C. The idea of adopting scientific measurements had been suggested as early as the 17th century, particularly by the astronomer Jean Picard (1620–1682), who proposed to take as a unit the length of a pendulum beating one second at sea-level, at a latitude of 45°. These suggestions took practical shape by a decree of the National Assembly in 1790 appointing a committee to consider the suitability of adopting either the length of the seconds pendulum, a fraction of the length of the equator or a fraction of the quadrant of the terrestrial meridian. The committee decided in favour of the latter and a commission was appointed to measure the arc of the meridian between Dunkirk and Mont Jany, near Barcelona. Another commission was also appointed to draw up a system of weights and measures based on the length of the metre and to fix the nomenclature, which on the report of the commission was established in 1795. It was not until 1799 that the report on the length of the metre was made. This was followed by the law of the 10th of December 1799 fixing definitely the value of the metre and of the kilogramme, or weight of a litre of water, and the new system became compulsory in 1801. It was found necessary however to pass an act in 1837, forbidding as and from the 1st of January 1840, under severe penalties, the use of any other weights and measures than those established by the laws of 1795 and 1799. The metric system is now obligatory in Argentina, Austria-Hungary, Belgium, Brazil, Chile, France, Germany, Greece, Italy, Mexico, Netherlands, Norway, Peru, Portugal, Rumania, Servia, Spain, Sweden, Switzerland. Its use is legalized in Egypt, Great Britain, Japan, Russia, Turkey and the United States. In 1875 there was constituted at Paris the International Bureau of Weights and Measures, which is managed by an international committee. The object of the Bureau is to make and provide prototypes of the metre and kilogramme, for the various subscribing countries.

In England action has frequently been taken both by individuals and by associations of commercial men for the purpose of endeavouring to make the metric system compulsory. A Decimal Association was formed in 1854, but did not make very much headway. A bill was introduced into parliament in 1864 to make the metric system compulsory for certain purposes, but owing to government objections a permissive bill was substituted and subsequently became law as the Metric Act 1864. It was, however, repealed by the Weights and Measures Act 1878. In 1871 another bill for compulsory adoption was rejected by the House of Commons on the second reading by a majority of five. In 1893 a representative delegation of business men pressed its adoption on the chancellor of the exchequer (Sir W. V. Harcourt), but he declined. But in 1897 a statute was passed, the Weights and Measures (Metric System) Act, which legalized the use in trade of the metric system, and abolished the penalty for using or having in one's possession a weight or measure of that system.

See also DECIMAL COINAGE and WEIGHTS AND MEASURES.

METROCLES, a Greek philosoper of the Cynic school, was a contemporary of Crates, under whose persuasion he deserted the views of Theophrastus. It was his sister, Hipparchia, whose romantic attachment to Crates is a fascinating sidelight on the almost truculent asceticism of the Cynics. He was a man of peculiar strength of character, and esteemed the joys of life so low that he was deterred from an early suicide only by the influence of Crates. His philosophical views, which were identical with those of Crates (*q.v.*), he expounded by precept and example with great success, and had among his pupils

Menippus of Sinope. Having weighed the probable pains and pleasures of approaching old age, he decided that life had nothing left for which he greatly cared, and drowned himself. He is said to have written several works, which he afterwards burnt. Of one, entitled Χρεῖαι, Diogenes preserves a single line (vi. 6).

METRODORUS, the name of five philosophers.

1. Metrodorus of Athens was a philosopher and painter who flourished in the 2nd century B.C. It chanced that Paullus Aemilius, visiting Athens on his return from his victory over Perseus in 168 B.C., asked for a tutor for his children and a painter to glorify his triumph. The inhabitants suggested Metrodorus as capable of discharging both duties, and it is recorded that Aemilius was entirely satisfied (see Pliny, *Nat. Hist.* xxv. 135).

2. Metrodorus of Chios was an important member of the Atomistic school. A pupil of Nessus, or, as some accounts prefer, of Democritus himself, he was a complete sceptic. He accepted the Democritean theory of atoms and void and the plurality of worlds, but held a theory of his own that the stars are formed from day to day by the moisture in the air under the heat of the sun. His radical scepticism is seen in the first sentence of his Περὶ φύσεως, quoted by Cicero in the *Academics* ii. 23 § 73. He says, "We know nothing, no, not even whether we know or not!" and maintains that everything is to each person only what it appears to him to be. Metrodorus is especially interesting as the teacher of Anaxarchus, the friend of Pyrrho, and, therefore, as the connecting link between atomism proper and the later scepticism. It cannot be decided whether a work entitled the Τρωϊκά quoted by Athenaeus (iv. 184 a) is by this, or another, Metrodorus. The same difficulty is found in the case of the Περὶ ἱστορίας referred to by the scholiast on Apollonius.

3. Metrodorus of Lampsacus was the disciple and intimate friend of Epicurus, and is described by Cicero (*de Fin.* ii. 28. 92) as "almost a second Epicurus." He died in 277 B.C. at the age of fifty-three, seven years before his master, who adopted his children and in his will commended them to the care of his pupils. The wife of Metrodorus was Leontion, herself, like many other women of the time, a member of the Epicurean society. Athenaeus (vii. 279 F.) quotes from the words of Metrodorus showing that he was in entire agreement with Epicurus, and was, if possible, even more dogmatic in his doctrine of pleasure. He censures his brother, Timocrates, who, though professedly Epicurean, maintained the existence of pleasures other than those of the body.

4. Another Metrodorus of Lampsacus was a pupil of Anaxagoras, and one of the earliest to attempt to interpret Homer allegorically. He explained not only the gods but also the heroes Agamemnon, Achilles, Hector, as representing primary elements and natural phenomena.

5. Metrodorus of Stratonice was a pupil, first of Apollodorus, and later of Carneades. He flourished about 110 B.C., and is reputed to have been an orator of great power. His defection from the Epicurean school is almost unique. It is explained by Cicero as being due to his theory that the scepticism of Carneades was merely a means of attacking the Stoics on their own ground. Metrodorus held that Carneades was in reality a loyal follower of Plato.

METRONOME (Gr. μέτρον, measure, and νόμος, law), an instrument for denoting the speed at which a musical composition is to be performed. Its invention is generally, but falsely, ascribed to Johann Nepomuk Maelzel, a native of Ratisbon (1772–1838). It consists of a pendulum swung on a pivot; below the pivot is a fixed weight, and above it is a sliding weight that regulates the velocity of the oscillations by the greater or less distance from the pivot to which it is adjusted. The silent metronome is impelled by the touch, and ceases to beat when this impulse dies; it has a scale of numbers marked on the pendulum, and the upper part of the sliding weight is placed under that number which is to indicate the quickness of a stated note, as M.M. (Maelzel's Metronome) 𝅗𝅥=60, or ♩=72, or ♪=108, or the like. The number 60 implies a second of time for each single oscillation of the pendulum—numbers lower than this denoting slower, and higher numbers quicker beats. The scale at first extended from 50 to 160, but now ranges from 40 to 208. A more complicated metronome is impelled by clock-work, makes a ticking sound at each beat, and continues its action till the works run down; a still more intricate machine has also a bell which is struck at the first of any number of beats willed by the person who regulates it, and so signifies the accent as well as the time.

The earliest instrument of the kind, a weighted pendulum of variable length, is described in a paper by Étienne Loulié (Paris, 1696; Amsterdam, 1698). Attempts were also made by Enbrayg (1732) and Gabory (1771). Harrison, who gained the prize awarded by the English government for his chronometer, published a description of an instrument for the purpose in 1775. Davaux (1784), Pelletier, Abel Burja (1790) and Weiske (also 1790) described their various experiments for measuring musical time. In 1813 Gottfried Weber, the composer, theorist and essayist, proposed a weighted ribbon graduated by inches or smaller divisions, which might be held or otherwise fixed at any desired length, and would infallibly oscillate at the same speed so long as the impulse lasted. Stöckel and Zmeskall produced each an instrument; and Maelzel made some slight modification of that by the former, about the end of 1812, which he announced as a new invention of his own, and exhibited from city to city on the Continent. It was, as nearly as can be ascertained, in 1812 that Winkel, a mechanician of Amsterdam, devised a plan for reducing the inconvenient length of all existing instruments, on the principle of the double pendulum, rocking on both sides of a centre and balanced by a fixed and a variable weight. He spent three years in completing it, and it is described and commended in the *Report of the Netherlands Academy of Sciences* (Aug. 14, 1815). Maelzel thereupon went to Amsterdam, saw Winkel and inspected his invention, and, recognizing its great superiority to what he called his own, offered to buy all right and title to it. Winkel refused, and so Maelzel constructed a copy of the instrument, to which he added nothing but the scale of numbers, took this copy to Paris, obtained a patent for it, and in 1816 established there, in his own name, a manufactory for metronomes. When the impostor revisited Amsterdam, the inventor instituted proceedings against him for his piracy, and the Academy of Sciences decided in Winkel's favour, declaring that the graduated scale was the only point in which the instrument of Maelzel differed from his. Maelzel's scale was needlessly and arbitrarily complicated, proceeding by twos from 40 to 60, by threes from 60 to 72, by fours from 72 to 120, by sixes from 120 to 144 and by eights from 144 to 208. Dr Crotch constructed a time measurer, and Henry Smart (the violinist, father of the composer of the same name) made another in 1821, both before that received as Maelzel's was known in England. In 1882 James Mitchell, a Scotsman, made an ingenious amplification of the Maelzel clock-work, reducing to mechanical demonstration what formerly rested wholly on the feeling of the performer.

Although "Maelzel's metronome" has universal acceptance, the silent metronome and still more Weber's graduated ribbon are greatly to be preferred, for the clock-work of the other is liable to be out of order, and needs a nicety of regulation which is almost impossible; for instance, when Sir George Smart had to mark the traditional times of the several pieces in the Dettingen Te Deum, he tested them by twelve metronomes, no two of which beat together. The value of the machine is exaggerated, for no living performer could execute a piece in unvaried time throughout, and no student could practise under the tyranny of its beat; and conductors of music, nay, composers themselves, will conduct the same piece slightly slower or quicker on different occasions, according to the circumstances of performance.

METROPOLIS (Gr. μήτηρ, mother, πόλις, city), properly a mother-city, and so the name of the parent state from which colonies were founded in ancient Greece (see Greece, sect. *History, Ancient*). The word was used in post-classical Latin for the chief city of a province, the seat of the government, and in particular ecclesiastically for the seat or see of a metropolitan bishop (see Metropolitan). It is thus used now for the capital of a country, which contains the various official buildings of the administrative departments, the Houses of Parliament, &c. In the case of London, the term "metropolitan" is sometimes applied to the whole area including the "City of London," *e.g.* "Metropolitan Asylums Board"; and sometimes, as in "Metropolitan Police," excludes the City, which has its own police force (see London).

METROPOLITAN (Lat. *metropolitanus*, Gr. μητροπολίτης), in the Christian church, the title of a bishop who has the oversight over bishops of subordinate sees. In the Western church the metropolitan is practically the same as the archbishop (*q.v.*); in the Eastern church he ranks above the archbishop, but below the patriarch (*q.v.*). Metropolitans first appear in the East in the 4th century as presiding over a province (*provincia* or *ἐπαρχία*), and their see is fixed in the principal town (*μητρόπολις*) of the province, which remains the normal custom both in East and West. In Africa, however, the metropolitan jurisdiction was exercised by the senior bishop (*primas*, *primae sedis episcopus*, *senex*) for the time being, a custom which prevailed for a time also in Spain. Thus, too, in the Scottish Episcopal Church and the Protestant Episcopal Church of America there are no metropolitans, the *primas* being the senior bishop.

METSU, GABRIEL (1630–1667), Dutch painter, was the son of Jacob Metsu, who lived most of his days at Leiden, where he was three times married. The last of these marriages was celebrated in 1625, and Jacomma Garnijers, herself the widow of a painter, gave birth to Gabriel in 1630. According to Houbraken Metsu was taught by Gerard Dow, though his early works do not lend colour to this assertion. It is certain, however, that he was influenced in turn by Jan Steen, Rembrandt, and Hals. Metsu was registered among the first members of the painters' corporation at Leiden; and the books of the gild also tell us that he remained a member in 1649. In 1650 he ceased to subscribe, and works bearing his name and the date of 1653 give countenance to the belief that he had then settled at Amsterdam, where he probably continued his studies under Rembrandt. One of his earliest pictures is the "Lazarus" at the Strassburg Museum, painted under the influence of Jan Steen. Under the influence of Rembrandt he produced the "Woman taken in Adultery," a large picture with the date of 1653 in the Louvre. To the same period belong the "Departure of Hagar," formerly in the Thoré collection, and the "Widow's Mite" at the Schwerin Gallery. But he probably observed that sacred art was ill suited to his temper, or he found the field too strongly occupied, and turned to other subjects for which he was better fitted. That at one time he was deeply impressed by the vivacity and bold technique of Frans Hals can be gathered from Lord Lonsdale's picture of "Women at a Fishmonger's Shop." What Metsu undertook and carried out from the first with surprising success was the low life of the market and tavern, contrasted, with wonderful versatility, by incidents of high life and the drawing-room. In no single instance do the artistic lessons of Rembrandt appear to have been lost upon him. The same principles of light and shade which had marked his schoolwork in the "Woman taken in Adultery" were applied to subjects of quite a different kind. A group in a drawing-room, a series of groups in the market-place, or a single figure in the gloom of a tavern or parlour, was treated with the utmost felicity by fit concentration and gradation of light, a warm flush of tone pervading every part, and, with that, the study of texture in stuffs was carried as far as it had been by Ter Borch or Dow, if not with the finish or the *brio* of De Hooch.

Metsu went to Amsterdam before 1655, married in 1658, and became a citizen of that city in 1659. One of the best pictures of Metsu's manhood is the "Market-place of Amsterdam," at the Louvre, respecting which it is difficult to distribute praise in fair proportions, so excellent are the various parts, the characteristic movement and action of the dramatis personae, the selection of faces, the expression and the gesture, and the texture of the things depicted. Equally fine, though earlier, are the "Sportsman" (dated 1661) and the "Tavern" (also 1661) at the Hague and Dresden Museums, and the "Game-Dealer's Shop," also at Dresden, with the painter's signature and 1662. Among the five examples of the painter at the Wallace Collection, including "The Tabby Cat," "The Sleeping Sportsman," which cost Lord Hertford £3000, is an admirable example technically considered. Among his finest representations of home life are the "Repast" at the Hermitage in St Petersburg; the "Mother nursing her Sick Child" of the Steengracht Gallery at the Hague; the "Amateur Musicians" at the Hague Gallery; the "Duet" and the "Music Lesson" at the National Gallery, and many more examples at nearly all the leading European galleries.

METTERNICH-WINNEBURG, CLEMENS WENZEL LOTHAR, PRINCE (1773–1859), Austrian statesman and diplomatist, was born at Coblenz on the 15th of May 1773. His father, Count Franz Georg Karl von Metternich-Winneburg zu Beilstein[1] (d. 1818), was a diplomatist who had passed from the service of the archbishop-elector of Trier to that of the court of Vienna; his mother was Countess Maria Beatrix Aloisia von Kagenegg. At the time of Clemens Metternich's birth, and for some time subsequently, his father was Austrian ambassador to the courts of the three Rhenish electors, and the boy was thus from the first brought up under the influence of the tone and ideas which flourished in the small German courts that lay within the sphere of influence of the France of the *ancien régime*.. In 1788 he went to the university of Strassburg, where he studied German constitutional law; but the outbreak of the French Revolution caused him to leave after two years. Metternich was a witness of the excesses of the mob in Strassburg, and he ascribed his life-long hatred of political innovation to these early experiences of the victory of liberal ideas. In 1790, by way of striking contrast, he was deputed by the Catholic bench of the Westphalian college of counts to act as their master of the ceremonies at the coronation of the Emperor Leopold II. at Frankfort, a function which he again performed at the coronation of Francis II. in 1792. The intervening time he spent at Mainz, attending the university and frequenting the court of the archbishop-elector, where his impressions of the Revolution were strengthened by his intercourse with the French *émigrés* who had made it their centre. The outbreak of the revolutionary war drove him from Mainz, and he went to Brussels, where he found employment in the chancery of his father, at that time Austrian minister to the government of the Netherlands. Here, in August 1794, he issued his first publication, a pamphlet in which he denounced the "shallow pates" of the old diplomacy and argued that the only way to combat the French revolutionary armies was by a *levée en masse* of the populations on the frontier of France—singular views for the statesman who was destined to be the last great representative of the old diplomacy and the greater part of whose life was to be spent in combating the national enthusiasms by which the revolutionary power of France was ultimately overthrown.

After a long stay in England, where he made the acquaintance of the prince of Wales (afterwards George IV.), Metternich went to Vienna; and on the 27th of September 1795 he married at Austerlitz the Countess Eleonore von Kaunitz, a grand-daughter of that Austrian chancellor who in many respects was his prototype. This alliance not only brought him great estates in Austria, but introduced him into the most exalted circles of Viennese society. Here he was well qualified to hold his own by reason of his handsome presence, the exquisite courtesy of his address and a certain reputation for gallantry. He was far, however, from being a mere carpet diplomatist. His interests were many and varied, and he found time for the serious study of natural science and medicine. In December 1797 he was chosen by the Westphalian counts as their representative at the congress of Rastadt, where he remained till 1799. This was his first experience of the great world of practical politics and especially of those rough diplomatists of the Revolution of whom in his letters he has left so vivid a description. In January 1801 he was appointed Austrian envoy to the elector of Saxony. His two years' stay at the court of Dresden was mainly useful to him by bringing him into touch with the many Russian and Polish families of importance; his serious diplomatic career did not begin till his appointment, in November 1803, as ambassador at Berlin. His instructions at the outset were to prevent Prussia from joining the alliance of Russia and Great Britain against the French Republic and to make himself agreeable to the representative of France; but shortly afterwards his part was exactly reversed, owing to the shifting of political forces which led to the war of the third coalition, and he laboured to secure the adhesion of Prussia to the alliance of Austria, Russia and Great Britain against Napoleon. His diplomacy was not successful; for though Prussia ultimately signed the treaty of the 5th of November 1805 with Austria and Russia, the influence of the emperor Alexander and the wound given to her pride by Napoleon's contemptuous violation of her territory had more to do with Prussia's decision than Metternich's veiled threats. His reward was the grand cross of the order of St Stephen and the appointment of ambassador at St Petersburg; but his commission to make himself agreeable to the French ambassador at Berlin was carried out to such excellent effect that, as a result of M. Laforest's reports, Napoleon requested that he might be appointed to represent Austria at the Tuileries, and in August 1806 Metternich took up his residence as ambassador in Paris.

---

[1] The family of Metternich, originally established in the county of Jülich, can trace its descent to the middle of the 14th century. In 1637 they received from the archbishop of Trier the countships of Winneburg and Beilstein. These were confiscated in 1803, and the lands of the suppressed abbey of Ochsenhausen, with the title of prince of the Empire, were granted by the edict as compensation. The new principality was "mediatized" in 1806 in favour of Württemberg; but in virtue of their short tenure of it the descendants of Prince Metternich enjoy the privileges of mediatized princes.

This was the beginning of his ever growing influence in European affairs. Established in the diplomatic character of an "honourable spy" in the very centre of Napoleon's power, he used his exceptional gifts of fascination not only to become a *persona grata* at the Tuileries, but to establish relations with those elements in the society of the empire which were already intriguing against Napoleon's power. His intimacy with Talleyrand and with Caroline Murat, Napoleon's sister, was destined to produce notable results later. Though on the look-out, however, for any chance of weakening the French emperor's power, Metternich was not at first sanguine of success, for he believed Napoleon to be invincible. For Austria the best policy seemed to him to be to temporize; he was willing, therefore, to co-operate with France in the agreement made between Napoleon and Alexander I. of Russia at Tilsit for the partition of the Ottoman Empire; failing the success of the efforts of Austrian diplomacy to break the Franco-Russian alliance, this would at least secure for the Habsburg monarchy a share of the spoils. With the postponement of Napoleon's Oriental schemes, however, the situation was once more changed. During the summer of 1808 Metternich had reason to suspect fresh designs of the French emperor against Austria, and his suspicions appeared to be confirmed when, during an interview on the 15th of August, Napoleon indulged in one of his violent tirades, denouncing Count Stadion's action in strengthening the Austrian armaments. In November Metternich was at Vienna, urging the Austrian government to an early declaration of war—for which the moment seemed to him opportune owing to the French losses in Spain, of which he had received exaggerated reports. On the 1st of January 1809 he was back in Paris, but no longer as a *persona grata*. At the outbreak of the war he was placed under arrest, in retaliation for the action of the Austrian government in interning two members of the French embassy in Hungary; and in June, on Napoleon's capture of Vienna, he was conducted there under military guard. In July he was exchanged at Komárom for the French diplomatists, and he was present with the emperor Francis at the battle of Wagram. At a council held on the 7th of July it was decided, on Metternich's initiative, to open negotiations for peace; next day Stadion tendered his resignation, which was provisionally accepted. Stadion was sent as diplomatic adviser to the headquarters of the archduke Charles, while Metternich took his place at the emperor's side. On the 4th of August Metternich was named minister of state, and soon afterwards was sent with Count Nugent to the peace conference at Altenburg, where Champagny attended as Napoleon's representative. The conference, however, dragged on without result, and the emperor Francis decided to open negotiations with Napoleon direct. Count Bubna was accordingly sent to Schönbrunn; the result was the French ultimatum which issued in the treaty of Schönbrunn (Vienna), signed by Prince Liechtenstein on behalf of the emperor Francis on the 14th of October 1809. With the negotiation and signature of this humiliating instrument Metternich therefore had nothing to do, though on the 8th of October he had been definitely appointed minister for foreign affairs, an office he was destined to hold for nearly forty years.

The position of the new minister was no easy one. By the treaty of Schönbrunn Austria was reduced to the position of a second-rate power, and by secret articles undertook during the continuance of the maritime war to limit her force of all arms to 150,000 men, and to dismiss from her service all officers or civil officers born in the territories of ancient France, Piedmont or the former Venetian republic. Weak as she had become, the menace of the future seemed even more disquieting. To the south she was divided from the French dominions by the Save; to the west and north the vassal states of France, traditionally her enemies, lay along the frontier; to the east was Russia, which as the reward for her alliance with Napoleon had received a portion of East Galicia as her share of the spoils, and to all appearance was firmly established in the Danubian principalities. Austria seemed hopelessly cut off by Napoleon from any chance of re-asserting her traditional preponderance in Germany, by Russia from any prospect of obtaining compensation at the expense of the Ottoman Empire. One false move on the part of those who guided its destinies, and the Habsburg monarchy might easily have ceased to exist altogether.

The saving factor in the situation was the improbability of the alliance between Napoleon and Alexander continuing, and the immediate task of Metternich was to hasten its dissolution, while securing Austria's safety in the East by bringing about the end of the Russo-Turkish War. It was a task of extreme delicacy; for any revelation of its true tendency might have thrown the emperor Alexander into the arms of France and plunged Austria into an unequal struggle for life and death with Russia on the banks of the Danube. Metternich was helped by the rapid development of the causes of disagreement between the French and Russian emperors. Early in 1810 Europe was full of contradictory rumours of war between France and Russia, of a marriage of Napoleon with a Russian grand duchess. Then suddenly came Napoleon's formal request for the hand of the Austrian archduchess Marie Louise. A proposal so nicely calculated to forward Metternich's plans was suspected of being due to his inspiration; certainly it was his influence that decided the emperor Francis to agree to an alliance which could not but be distasteful to him and was resented as a crowning humiliation by the proud aristocrats of Vienna.

On the 13th of March 1810 Metternich left Vienna for Paris in company with the archduchess. His object was to use so favourable an occasion for obtaining the abrogation of some of the more onerous articles of the treaty of Schönbrunn, and for coming to some arrangement whereby the serious inconvenience caused in Austria by Napoleon's coercion of the pope might be obviated. His diplomacy, however, met with but slight success. His efforts to persuade Pius VII. to purchase a measure of liberty of action by concessions to Napoleon broke down on the gentle old man's refusal to traffic with his principles. From Napoleon he extracted a lame apology for the execution of Andreas Hofer, the reversal of a few sequestrations and, as a crowning grace, the abrogation of the article of the Schönbrunn treaty limiting Austrian armaments. In the matter of restoring the access of Austria to the Adriatic, Napoleon would make no concession; his answer to Metternich's representations was only a commercial treaty which failed to obtain ratification at Vienna. Anything further, *e.g.* an exchange of the Illyrian provinces for Galicia, must depend on the attitude of Austria in the forthcoming Russian war which, in an interview of the 20th of September, Napoleon declared to be now inevitable.

On the 10th of October Metternich was back in Vienna, where his presence was urgently needed. The policy of a Franco-Austrian *entente* was popular with the public and the army, resentful of the treacherous attitude of Russia in the late war, but in the powerful circles of the court it had scarce an adherent. Prince Metternich himself, who had acted as foreign secretary during his son's absence, favoured an understanding with Russia, and was even believed to be intriguing to retain the portfolio of foreign affairs, which would have meant the victory of the Russian party. On the other hand, the French party were clamouring for the speedy conclusion of a definite alliance with Napoleon. By an admirably clear *exposé* of the situation Metternich won over the emperor Francis to that middle course, the policy of armed abstention, which was to be the basic principle of his diplomatic action during the crisis of the coming years. An alliance with Russia, he argued, would be worse than useless; Austria would at any time obtain better terms from the tsar's growing needs. An alliance with France would be one with "a power whose exclusive object is the destruction of the old order of things, which has hitherto found its defence in Austria." Alone of European Powers Austria still had the possibility of choice; let her work for the preservation of peace and at the same time remain free, should war break out, to make her own terms. It would little serve Austria's interests to become the ally of Russia, merely to serve as a barrier behind which the emperor Alexander could carry out his designs on Turkey in safety. In an interview with Count Shuvalov, the Russian agent, Metternich roundly declared that the maintenance of the integrity of Turkey was for Austria the question of supreme interest.

With the approach of the Russo-French War the situation became increasingly difficult. The partisans of a Russian alliance remained powerful and clamorous; but Metternich did not share the doubts as to the outcome of Napoleon's invasion of Russia, which he believed would leave Austria, if she remained neutral, isolated amid a huge European confederation. To him the only safe course seemed to be to offer the French emperor substantial assistance, stipulating for some *quid pro quo* in the settlement to follow the war. The emperor Francis shared this view; and on the 14th of March a treaty of alliance was signed by which Austria agreed to support the French army with an army corps of 30,000 men operating from Galicia. This treaty was ratified at Vienna on the 25th of March, the day of Napoleon's passage of the Niemen. It was characteristic of Metternich's diplomacy that the Austrian generals in Galicia were ordered to act only on the defensive, and that the court of St Petersburg was informed that Austria would only take part in the war as a principal should Russia force her to do so.

This cautious attitude was soon justified by the astounding developments of the Moscow campaign. When the full extent of the catastrophe that had overwhelmed Napoleon's army became known, Metternich realized the advantageous position in which Austria lay for exploiting the changed situation. His first idea was that France should commission Austria to mediate a peace in Russia and in England (Despatch of Otto, November 10); but, as affairs developed, this was replaced by the policy of temporizing until Austria should be in a position to intervene with decisive effect. Napoleon's demand that Austria should raise her contingent from 30,000 to 100,000 men was, indeed, from Metternich's point of view doubly opportune: for it enabled him quietly to assume that the treaty of the 14th of March, which stipulated only for an "alliance limitée," had been abrogated by Napoleon's own act; that Austria had reverted to a position of neutrality; and that, should she take part in the war, it would no longer be in a subordinate character but as a principal. "Le passage de la neutralité à la guerre," said Metternich to the emperor Francis, "ne sera possible que par la médiation armée"; which meant in effect that Austria required time to complete her armaments. To gain this time was, during the weeks that followed, the object of his diplomacy. For this purpose he encouraged Napoleon to believe that Austria was prepared for a settlement on terms very favourable to the French emperor; with the result that Napoleon, though he would not hear of a "mediation," not only consented to, but pressed for, Austrian "intervention" (*entremise*). But Metternich had made up his mind that the only chance of an effective restoration of the Habsburg influence in Europe lay in using this opportunity for destroying or limiting Napoleon's power, and he had already opened negotiations with the allied courts, with a view to enforcing a common agreement as to a basis of peace, when the indecisive battle of Lützen (May 2) gave him the opportunity of making his policy of mediation effective. Count Stadion was now sent to the emperor Alexander to lay before him the terms on which Austria was prepared to mediate; he was also to "agree to the bases of an active military co-operation on our part, in the event of the non-success of our efforts on behalf of peace." On the 20th of March Napoleon gained another indecisive victory at Bautzen, which still further strengthened Metternich's position; for Napoleon allowed himself to be persuaded into signing the ill-omened armistice of Pleiswitz (Poischwitz), on the 4th of June, and to become entangled in the insincere negotiations of the congress of Prague. Austria thus had time to complete her armaments. Meanwhile, on the 14th and 15th of June, were signed at Reichenbach the treaties of alliance between Great Britain, Russia and Prussia, by which the signatory Powers agreed neither to negotiate nor to conclude treaty or truce with Napoleon except by common consent. In an interview with the emperor Alexander, Metternich now presented the terms which he proposed to offer to Napoleon, and on this basis a treaty between Austria, Russia and Prussia was agreed to, Austria contracting to put 150,000 men into the field, should Napoleon reject the ultimatum, and not to make peace without the consent of Russia and Prussia—which in effect involved that of Great Britain also.

Before this second treaty of Reichenbach was signed (June 27), Metternich went on Maret's invitation to Dresden, where on the 26th he had the famous interview with Napoleon. The whole scene was on his part a masterpiece of Machiavellian diplomacy. The terms he offered to the emperor were so favourable that he has been denounced by every Prussian historian since as the enemy of Germany; while French historians have enlarged on Napoleon's infatuation in rejecting them. In spite of the fact that the draft of the treaty of Reichenbach was in his pocket, he posed as the impartial "mediator," with a leaning in favour of Napoleon, assuring the emperor "on his honour as a German count" that Austria was still "free from all engagements," which was true only in so far as the treaty was not signed till the next day. Metternich's object was, in fact, only to gain an extension of the armistice till the 10th of August, on which date Schwarzenberg had declared that he would be ready to take the offensive. As for the terms offered to Napoleon his acceptance of them need not hamper the plans of the Allies; for the consent of Great Britain would have to be obtained, and, moreover, Napoleon was sure before long to provide an excuse for a fresh breach; his rejection of them, on the other hand, would be a blow to his waning popularity in France. The interview was long and stormy; Napoleon struggled vainly in the toils; in his excitement he dropped his hat, which the imperturbable Metternich did not condescend to pick up; "Napoleon," he records in his *Memoirs*, "seemed to me small." Metternich, however, gained his immediate point; the armistice was extended to the 10th of August. At midnight on that date, Napoleon not having come to terms, Metternich gave orders for the lighting of the beacons that signalled to the Austrian army in Silesia the outbreak of the war.

Napoleon's victory at Dresden (Aug. 26 and 27) for the moment brought discord into the counsels of the Allies and threatened the ruin of Metternich and his plans; but the successive defeats of Vandamme at Kulm (Aug. 28), of Macdonald at Katzbach (Aug. 29) and Oudinot at Grossbeeren (Aug. 30) completely altered the aspect of affairs; and on the 9th of September Metternich signed at Töplitz a treaty with Russia which committed Austria yet more closely to the policy of the Allies. Then followed the battle of Leipzig (Oct. 16–18) and the advance of the Allies into France. The diplomatic situation throughout the campaign was, from the Austrian point of view, one of extreme delicacy. The necessity of curbing the power of Napoleon and rendering him for ever incapable of again oversetting the balance of Europe was practically the only object Austria had in common with her allies. She did not share the implacable resentment with which Great Britain pursued Napoleon; she watched with alarm the development of the ambitions of Alexander I., which threatened to substitute a Russian for a French supremacy in Europe; she was far from sympathizing with the noisy enthusiasm of the patriots of the War of Liberation for a united Germany, in which the traditional influence of the Habsburgs would be balanced or overshadowed by that of Prussia. Metternich had no wish to see the husband of Marie Louise ousted in favour of the Bourbons, who had little reason to be grateful to Austria; still less did he desire to see on the throne of France Alexander's protégé Bernadotte, whose name was being whispered in the Paris salons as the destined saviour of his native country. But if Napoleon was to remain sovereign of France, it must be not by his own force, but by grace of his father-in-law, and hedged round with limitations which would have made him little more than the lieutenant of the Habsburg monarchy. This was the secret of the moderate terms of accommodation ostentatiously offered by Metternich to Napoleon at various stages of the campaign. From Frankfort he sent, through General de Saint-Aignan, a diplomatist on whose indiscretion he could rely, an informal offer of peace on the basis of France's "natural frontier," the Rhine, the Alps and the Pyrenees. The famous manifesto of Frankfort, issued on behalf of the Allies (Dec. 4, 1813), contained no such offer of acceptable terms; but Metternich's object was attained; for Napoleon refused to be drawn into the trap, and the French people cursed the emperor's infatuation in refusing a settlement which, from what had leaked out of Saint-Aignan's mission, they believed would have satisfied the legitimate ambitions of France. On the other hand, Metternich did his best to oppose a too rapid advance of the allied forces on Paris, which would have played into the hands of Russia and Prussia; and it was to his initiative that the conferences of Châtillon were due. Only when the breakdown of the negotiations made it clear that Napoleon had seen through his plans, and preferred the chances of war to the certainty of ruin or of surviving only as the puppet of Austria, did Metternich join with Castlereagh in pressing upon the tsar the necessity for restoring the Bourbons. On the 1st of March 1814, he set his hand to the treaty of Chaumont, of which the immediate object was the restoration and preservation of the old dynasty in a France reduced to her "legitimate frontier." In other respects, however, the treaty was a triumph for Metternich; for it laid down that at the final settlement Germany was to be reconstituted as a confederation of sovereign states, and it also did much to temper the fear of a Russian dictatorship by consecrating the principle of that concerted action of the Great Powers, in affairs of international interest, which after Napoleon's fall was to govern the European system. On the 10th of April Metternich arrived at Paris, ten days after its occupation by the Allies. He was now at the height of his reputation; on the 20th of October 1813, two days after Leipzig, he had been created an hereditary prince of the Austrian Empire; he now received from the emperor Francis a unique honour: the right to quarter the arms of the house of Austria-Lorraine with those of Metternich. At the same time (April 21) the countship of Daruvar was bestowed upon him. On the 30th of May Metternich set his signature to the treaty of Paris, and immediately afterwards accompanied the emperor Alexander and King Frederick William on a visit to England. On the 18th of July he was back in Vienna, where the great congress was to meet in the autumn. The dignity of a Hungarian magnate was bestowed upon him before it assembled.

At the congress Metternich's charm of manner and great social gifts gave him much personal influence; the ease and versatility with which he handled intricate diplomatic questions, too, excited admiration; at the same time he was blamed for his leaning to intrigue and *finesse* and for a certain calculated disingenuousness which led to an open breach with the emperor Alexander, who roundly called him a liar. In the difficult questions of Poland and Saxony the honest and conciliatory attitude of Castlereagh was of more avail in reaching an acceptable settlement than all Metternich's cleverness. If in the Italian and German questions, however, Austria's views triumphed, this was due to the foresight displayed in Metternich's diplomacy during the campaigns and to the address with which he handled the questions at issue at the congress. The complacency of Hardenberg had allowed Austria alone to negotiate with the states of the Confederation of the Rhine with a view to detaching them from Napoleon; and he had used this opportunity to render impossible the idea of a united Germany. On the 8th of October 1813 he had signed with Bavaria the treaty of Ried, which in the event of the liberation of Germany guaranteed to Bavaria a sovereign and independent status. This instrument, which was reinforced by a secret treaty signed at Paris on the 3rd of June 1814, served as a model for similar agreements with other courts; and the principle involved was, as mentioned above, included in the treaty of Chaumont. Thus all the unionist ideals, represented at the congress by Stein, were sterilized from the outset; and the Act of Confederation embodied in the Final Act of Vienna gave to Germany exactly the form desired by Metternich as best calculated to perpetuate Austrian preponderance (see GERMANY: *History*). The same was true of the settlement of Italy. The question here was complicated by the treaty of alliance signed by Metternich with Murat as the price of his treason to Napoleon. But Metternich from the first had known that the treaty was but a temporary expedient; that Great Britain would never recognize "the person at the head of the government of Naples"; and that sooner or later Murat himself would afford excuse enough for tearing the treaty up. Not Murat's dream of an Italy united under his own rule, but the traditional Austrian policy of possession in the north and preponderance throughout the Peninsula was Metternich's goal, and this he secured at the congress. Murat, in view of Austria's engagements, was suffered to survive for the time being; he himself shattered the alliance during the Hundred Days; and the Bourbons returned to Naples, pledged by a secret agreement to attune their policy to that of Vienna (see NAPLES: *History*).

Metternich, then, emerged from the congress of Vienna confirmed in the confidence of his sovereign, and therefore supreme in Germany and in Italy. To him had been due the marvellous recovery of the Habsburg monarchy; in spite of Gentz's lament that in the latter stages of the campaign of 1814 "Europe" had been substituted for "Austria" in his diplomacy, Metternich had acted throughout first and foremost in the interests of Austria, as he was bound to do. This, too, gives the key to his policy after 1815, the policy of using the European concert, established by the treaty of Chaumont and the Paris treaty of the 20th of November 1815, as an instrument for ensuring the "stability" of Europe by suppressing any "revolutionary" manifestations by which the settlement made at Vienna might be endangered.

After the campaign of Waterloo and Napoleon's second downfall Metternich was again in Paris, where he co-operated with the emperor Alexander and Castlereagh in securing tolerable terms of peace for France. A few days after the signing of the two treaties of the 20th of November 1815, he left Paris for Milan, where he met the crown prince Louis of Bavaria and Baron von Rechberg, with whom he came to terms on certain outstanding questions between Austria and Bavaria, terms embodied in the treaty of Munich of the 14th of April 1816. During his visit to Italy, which he repeated in 1816 and 1817, Metternich could not but be impressed with the general signs of discontent with Austrian rule. Neither was he blind to the true causes of this discontent: the atrophy of the administration owing to its rigid centralization at Vienna, and the policy of enforcing Germanism on the Italians by a ruthless police system. He made half-hearted proposals for removing something of both these grievances; but his terror of revolution from below made him fearful of reforms from above. While therefore in Prussia king and ministers were labouring hard to remodel and consolidate the monarchy, Metternich did next to nothing to reform the most obvious abuses of the Austrian Empire. Yet the fault was not wholly, or mainly, his. Sir Robert Gordon,[1] in a letter to Castlereagh (dated Florence, July 11, 1819), gives the true reason for this attitude: "How much is it to be desired that the superior talents of Prince Metternich were more occupied with the revision and improvement of the administration of affairs in his own country. He is too enlightened not to perceive its most palpable defect . . . He might have courage to sacrifice himself for the institution of effective remedies, but he fears that the confiding benignity of his Sovereign might afterwards be dissuaded from the just and vigorous application of them." (F.O. *Austria. Gordon.* Jan.–Dec., 1819.) Metternich's power, after all, was limited by the goodwill of his master, the emperor Francis, and Francis trusted him precisely because he seemed to share his own fanatical hatred of all change. It is this fact that seems to explain Metternich's feverish anxiety to justify his obscurantist attitude to himself and to the world. It suited him to ascribe the general discontent, of which the causes were not obscure, to the wanton agitation of the "sects," and his agents all over Europe earned their pay by supplying him with plentiful proof of the correctness of his contention. The result was well summed up in another letter of Gordon to Castlereagh (ibid. No. 26, Florence, July 12, 1819). "Nothing," he writes, "can surpass Prince Metternich's activity in collecting facts and information upon the inward feelings of the people; with a habit of making these researches he has acquired a taste for them. . . . The secrecy with which this task is indulged leads him to attach too great importance to his discoveries. Phantoms are conjured up and magnified in the dark, which probably if exposed to light would sink into insignificance; and his informers naturally exaggerate their reports, aware that their profit is to be commensurate with the display of their phantasmagoria." The judgment is instructive, coming as it does from a diplomatist in intimate touch with Metternich and in general sympathy with his views.

There was, none the less, method in this madness. Behind the agitations of the "sects" loomed the figures of the emperor Alexander and of his confidant Capo d'Istria, "the Coryphaeus of Liberalism," whose agents, official or unoffical, were intriguing in every country in Europe, and not least in Italy. The factor, then, that determined Metternich's attitude was not so much a dread of revolutions in themselves as of revolutions exploited by the "Jacobin" tsar to establish his own preponderance in Europe. Metternich's object, then, in respect of the revolutionary agitations, was twofold: he wished to impress Alexander with the peril of this imperial coquetting with democratic forces; he wished to convince the "sects" that they could not rely on the tsar's support. He succeeded in both these objects during the period from the congress of Aix-la-Chapelle in 1818 to that of Verona in 1822. (See ALEXANDER I. OF RUSSIA; EUROPE: *History*.)

On his way to the congress of Aix, Metternich spent a few days at Frankfort, where his presence was sufficient to settle the difficult question of the constitution of the federal forces. It was a signal triumph. "You can have no idea of the effect produced by my appearance at the diet," he wrote exultingly to his wife, "I have become a species of moral power in Germany and, perhaps, even in Europe" (*Mem.* iv. 64). This self-complacency was characteristic of the man; but, if we accept his view of "morality," the boast scarce seems exaggerated. In the main questions debated at Aix, indeed, it was Castlereagh's influence rather than that of Metternich which prevailed; the abolition of the supervision of French affairs by the committee of ambassadors was, for instance, carried against his opinion. But it was at Aix that Metternich was not only reconciled with Alexander, but laid the foundations of that personal influence over the tsar that was to bear notable fruit later; from Aix, too, where he arrived at a complete understanding with King Frederick William III. and the Prussian ministers, dates his preponderant influence in German affairs.

The outlook in Europe at the beginning of 1819 seemed to Metternich particularly gloomy. In France the ministry of Decazes was, in his opinion, under the inspiration of the Russian ambassador Pozzo di Borgo, heading straight for a new revolution; in Italy Russian agents were openly carrying on a Liberal propaganda; Germany, and notably the Prussian bureaucracy, was honeycombed with revolutionary ideas. Then came the news of the murder of Kotzebue (March 23). Metternich was in Italy at the time; but he determined at once to take advantage of this senseless crime to carry his views in the matter of muzzling the Liberal agitation in Germany. In the summer he met King Frederick William and Prince Hardenberg at Töplitz; a conference that resulted in the indefinite postponement of the Prussian constitution and in a secret agreement (Aug. 1) on the proposals to be laid before a conference of German ministers to be held at Carlsbad in the same month. The result of this were the famous Carlsbad Decrees (*q.v.*), by which liberty of speech and of the press was abolished throughout Germany. The Vienna conferences that followed in November and issued in the Final Act of the 15th of May 1820, was not so complete a triumph for Metternich; but his diplomacy, none the less, had succeeded in riveting on Germany the yoke of the Austrian system, which it was to bear with but partial and temporary relaxations for nearly thirty years (see GERMANY: *History*).

The year 1820 was marked by critical events which drew Metternich's attention once more from the affairs of Germany to those of Europe at large. The revolution in Spain, with which Austria had no immediate concern, interested him little; but his attitude towards it is characteristic and illuminating. The emperor Alexander for whom the idea of the confederation of Europe was an article of faith, proposed a European intervention and offered to march a Russian army through northern Italy into Spain. Metternich, to whom the remedy seemed far worse than the disease, covered his dissent from this proposal with a great display of principle. The ills of Spain were "material," those of Europe at large "moral"; and the European Alliance was there to deal with moral, not material, troubles. The revolution that followed in Naples, however, necessitated a different attitude. Strictly speaking, it concerned Austria alone; but Metternich was anxious to range Alexander openly against Italian Liberalism, and he therefore consented to the question being laid before a congress to be assembled at Troppau. The congresses of Troppau (1820) and Laibach (1821) are dealt with elsewhere (see EUROPE: *History*; ITALY: *History*, and the articles *s. v.*). For Metternich they represented a signal triumph. Not only did he complete his ascendancy over the emperor Alexander; but he openly committed all the Powers to an approval of the Austrian system in Italy, a success that outweighed his failure to win over Great Britain to the general principle of intervention enunciated in the Troppau Protocol. His attempt, however, to crown his system in Italy by setting up a central committee on the model of the Mainz commission was defeated at the congress of Verona (1822) by the opposition of the Italian princes headed by the pope and the grand duke of Tuscany.

The sort of moral dictatorship which Metternich had acquired on the continent was shattered by the developments of the Eastern Question. At first, indeed, the peril of a Russian attack on Turkey had drawn Austria and Great Britain closer together, and in a meeting at Hanover in October 1821 Metternich and Castlereagh had come to an understanding as to using the Holy Alliance to prevent Alexander from acting independently of the concert. But Metternich's hope that the Greek revolt would burn itself out "beyond the pale of civilization" was belied by events; and even before Castlereagh's death it was clear that Great Britain would have sooner or later to adopt a policy of intervention opposed to all Metternich's ideas. The breach was hastened by the accession to office of George Canning, who hated Metternich and all his ways. At Verona in 1822 the withdrawal of Great Britain from the system of the continental Allies was proclaimed to all the world; in March 1823 Canning recognized the Greek flag. This opened up the whole Eastern Question in the precise form that Metternich had sought to avoid; for the action of Great Britain involved a move on the part of Russia, jealous of her prestige in the Levant, and thus led ultimately to a rearrangement of the relations of the Powers which, so far as the affairs of the Ottoman empire were concerned, left Austria isolated. It is impossible here even to outline Metternich's diplomacy during the eleven years between the outbreak of the Greek revolt and the signature of the treaty of London (1832) by which the kingdom of Greece was established. The principles that guided it are, however, sufficiently simple. In common with Great Britain he desired to maintain the integrity of the Ottoman Empire as a barrier against Russian domination in the Balkan peninsula; he wished also to avert a Russo-Turkish war, not only for the above reason, but also because this would involve the breakdown of the system by which he hoped to curb the revolutionary forces in the West. He therefore attempted, and for a while successfully, to persuade the tsar that the Greeks were only "ordinary rebels against legitimate authority." But, when this expedient failed, he was the first to suggest the complete independence of Greece, which seemed to him less dangerous to Austrian interests than a tributary principality on the model of Moldavia and Wallachia. In the end his attitude was one of abstention and protest, since he rightly considered that the action of the Powers which culminated in the treaty of London was fatal to the doctrine of legitimacy, on which his system was based.

---

[1] Sir Robert Gordon (1791–1847), brother of the 4th earl of Aberdeen, was between 1815 and 1821 associated with Wellington as minister plenipotentiary at Vienna.

The Greek question was not finally settled when the outbreak of the revolutions of 1830 threatened the overthrow of the whole structure of 1815 in the West. Events which seemed to involve the complete ruin of Metternich's system gave it in effect, however, a new lease of life. Austria, isolated by the events in the East, was once more brought into touch with Russia by a crisis that concerned both Powers equally. On the receipt of the news of the July revolution in Paris Metternich hastened to meet Count Nesselrode at Carlsbad; and, though the Russian statesman refused to commit himself to the idea of an immediate reconstitution of a league of the three autocratic Powers, a common basis of action was agreed upon, and the foundations were laid for that cordial understanding that ripened in the meeting of Münchengrätz three years later. Meanwhile, though his language was still "European," Metternich's attitude towards the revolutions was wholly Austrian. He preached the sacred duty of intervention, but he refused to intervene, save where the interests of the Habsburg monarchy were directly concerned. He was even the first to recognize the revolutionary government of Louis Philippe (Sept. 8); he answered the appeal of the king of Holland for help with an ironical reference to the geographical situation of Austria; he did not even interfere with the revolutions in Germany and Poland. But when in Italy revolts broke out that threatened the Austrian hegemony, he acted with promptitude and decision, in spite of the threatening attitude of France; in the spring of 1831 Austrian bayonets restored order in Parma, Modena and the Papal States. Yet even here Metternich showed an unwonted moderation: not only did he soon withdraw the Austrian troops from Ancona, but he took the initiative in impressing on the papal government the urgent necessity for drastic reform. This attitude was, indeed, mainly determined by the uncertainty as to the relations of the three autocratic courts on whose co-operation the effectiveness of a policy of repression ultimately depended; and Metternich's next work was to attempt to re-cement the broken alliance. With Prussia he had little difficulty; the timidity of King Frederick William III. had increased with years and the events of 1830, and the Prussian and Austrian governments came to complete understanding on a common policy in Germany. Its first fruits were the additional articles appended by the Federal Diet (June 28, 1832) to the Vienna Final Act, by which the control of the diet over the state legislatures was increased. As for Russia, Count Nesselrode at first maintained the reticent attitude he had adopted at Carlsbad; but finally, in 1833, Metternich met the emperor Nicholas I. himself at Münchengrätz and by adroit flattery won him over to his views. The Berlin convention of the 15th of October 1833, which reaffirmed the divine right of intervention, was a fresh triumph for Metternich's diplomacy. This had been rendered possible by the change in Russia's attitude towards the Turkish question after 1829, which made a co-operation of Austria and Russia possible in the East (see MEHEMET ALI); and in its turn it made possible the maintenance for a while longer of the Austrian system in Germany.

The convention of Berlin marked the last conspicuous intervention of Metternich in the general affairs of Europe. "The Holy Alliance of the East," as Palmerston called it, served the immediate purpose of securing "stability" in the countries immediately subject to the Powers composing it; it made no attempt at more than "moral" intervention in questions, *e.g.* that of Spain, that lay beyond its own sphere of influence; and the development of the Eastern Question, leading to the rapprochement between Russia and Great Britain, though Austria joined the Quadruple Alliance of 1840, tended to loosen the cordial ties between the courts of Vienna and St Petersburg. The Straits Convention of 1841, by which France was formally readmitted to the concert, was due largely to Metternich's initiative; so, too, was the ill-judged effort of the continental Powers in 1847 to interfere in favour of the *Sonderbund* in Switzerland. But, on the whole, the growing crisis within the Habsburg monarchy itself was sufficient to deter Metternich from foreign adventures. So long as the emperor Francis lived all question of reform was impossible, and when he died, in 1835, the rusty machinery of the Austrian administration was too completely out of gear to be set right by anything short of a complete reconstruction, to which Metternich was too old to set his hand, even had he had the inclination to do so. He was too experienced not to realize the sickness of the state, but he was content to veil it from himself and to attempt to veil it from others. The world was not deceived; but it was not until the Vienna mob, in 1848, was thundering at the door of his cabinet that Metternich himself realized the truth to which he had tried to blind himself. With his fall his system also fell; and his flight from Vienna was the signal for the revolutions by which in 1848 all the countries under Habsburg influence were convulsed.

The resignation of Prince Metternich, handed in on the 13th of March 1848, was accepted by the emperor on the 18th, and the prince and his family at once left for England. Here he lived in great retirement, at Brighton and London, until October 1849, when he went to Brussels. In May 1851 he went to his estate of Johannesberg, where he was visited by King Frederick William IV. and Bismarck; in September he returned to Vienna. The events of 1848 had not shaken his self-complacency; they seemed to him rather to confirm the soundness of his own political principles, which would have scotched the evil betimes had not the weakness of others allowed the forces of disorder to gather strength. But though, in his own opinion, triumphantly vindicated, he did not again take office; he maintained, none the less, as a critic and adviser no mean influence on the counsels of the Austrian court, though it was contrary to his advice that Austria signed the treaty of the 2nd of December 1854 with France and Great Britain. He lived to see the beginning of the struggle of France and Italy against Austria, dying on the 11th of June 1859.

Probably no statesman of all time has, in his own day, been more beslavered with praise and bespattered with abuse than Metternich. By one side he was reverenced as the infallible oracle of diplomatic inspiration, by the other he was loathed and despised as the very incarnation of the spirit of obscurantism and oppression. The victories of democracy brought the latter view into fashion, and to the Liberal historians of the latter part of the 19th century the name of Metternich was synonymous with that of a system in which they could recognize nothing but a senseless opposition to the forces of enlightenment. A juster estimate of the man and his work has, however, become possible as the age has moved farther away from the smoke of controversy. On the whole, history has tended to endorse the sane judgment on Metternich pronounced by Castlereagh when he was first brought into diplomatic contact with him. Writing from Chaumont to Lord Liverpool, on the 26th of February 1814, he said: "Austria both in army and government is a timid Power. Her minister is constitutionally temporizing—he is charged with more faults than belong to him, but he has his full share, mixed up, however, with considerable means for carrying forward the machine, more than any other person I have met with at Head Quarters" (F. O. 2 France, *From Lord Castlereagh*). This gives the key to Metternich's character and policy: Austria was a timid Power, and Metternich was an Austrian minister. His policy of "stability," so necessary for the Habsburg monarchy, at least secured a long period of peace for Europe at large. Europe, her strength renewed, passed a severe judgment on the statesman who acted on the assumption that what the generality of people wanted was peace, not liberty; and justly, in so far as his pessimism led him to convert what might have been legitimate as a temporary counsel of expediency into an immutable principle. But, as Demelitsch points out, it will be time for *Austrians* to condemn him when Austria shall have survived half a century of constitutional experiment under the dual monarchy.

Of the *technique* of diplomacy Metternich was a master. His despatches are models of diplomatic style. If they have any fault, it is that they are often over-elaborate, the work of a man who evidently loves diplomacy for its own sake and glories in the fine turn of a phrase. In this respect they are comparable to those of Canning, who modelled himself upon Chateaubriand; they are in vivid contrast to the crabbed businesslike letters of Castlereagh. Metternich almost invariably begins his despatches and his reports with a broad discussion of the principles involved in the case in point, and argues from these down to the facts. In this again he is in sharp contrast with Castlereagh, who, with characteristic British practical sense, politely sweeps the principles aside and prefers to argue upward from the facts. Yet Metternich's phrase-making was often the result of astute calculation. His diplomatic genius was never so well displayed as in disguising perilous issues in phrases that soothed even when they did not convince; and, like Gladstone after him, when the occasion demanded it, he was master of the art of appearing to say much when in fact he said nothing. When he wished to make his meaning plain, no one could do so more clearly; when he wished to be reticent, no reticence could have been more pleasingly eloquent.

In private life Metternich was a kind, if not always faithful, husband and a good father, devoted to his children, of whom he had the misfortune to lose several before his death. He was three times married. His second wife, Baroness Antonie von Leykam, Countess von Beilstein, died in 1829; his third wife, Melanie, Countess Zichy-Ferraris, died on the 3rd of March 1854. Of his sons three survived him: Richard Clemens Lothar (1829–1895), his son by his second marriage, who was Austrian ambassador in Paris from 1859 to 1871; Prince Paul (1834–1906), and Prince Lothar (1837–1904), his sons by his third marriage. His grandson Prince Clemens (b. 1869), son of Prince Paul, married in 1905 Isabella de Silva Carvajal, daughter of the marquis de Santa Cruz.

BIBLIOGRAPHY.—A vast mass of unpublished material for the life of Prince Metternich exists in public and private archives; to some of those in the F.O. Records references are given in the bibliography to chap. I. of vol. x. of the *Cambridge Mod. Hist.* Of published documents the most important are in the collection *Aus Metternichs nachgelassenen Papieren* (8 vols., 1880–1884), edited by his son, Prince Richard Metternich. There is a complete French translation issued contemporaneously, and an English version, of which only five volumes (down to 1835) have been published, under the title *Memoirs, &c.* (London, 1880–1882). These *Memoirs*, especially the autobiographical parts, must be read with considerable reserve; even the official letters and documents, which are their most valuable contents, have been to a certain extent "edited." See also Count Anton Prokesch-Osten (the younger) *Aus dem Nachlass von Prokesch-Osten* (2 vols., Vienna, 1881); the writings and correspondence of Friedrich von Gentz (*q.v.*), especially as collected under the title *Oesterreichs Theilnahme an den Befreiungskriegen*; Wilhelm Oncken, *Österreich und Preussen im Befreiungskriege* (1876–1879); A. Beer, *Zehn Jahre österreichischer Politik, 1801–1810* (1877); *Die Finanzen Österreichs* (1883); *Die orientalische Politik Österreichs seit 1774* (1883); T. T. de Martens, *Recueil des traités, &c.*, vols. iii. and iv.; Thiers, *Hist. du consulat et de l'empire*, which was frequently commended by Metternich himself as giving an accurate account of his policy, a statement, however, controverted by Albert Sorel, whose *l'Europe et la révolution française*, gives a detailed and masterly account of Metternich's share in the overthrow of Napoleon. Fedor von Demelitsch's *Fürst Metternich und seine auswärtige Politik*, vol. i., to 1812 (Munich, 1898), is an elaborate and useful analysis of Metternich's foreign policy, based on a large mass of unpublished archives. The best short biography of Metternich is that by A. Beer in *Der neue Plutarch* (1877), vol. v.; but both this and Colonel G. B. Malleson's *Life of Metternich* (London, 1888) were written before the publication of the important works of Demelitsch and Sorel. (W. A. P.)

METZ, a town, first-class fortress and episcopal see of Germany, in the imperial province of Alsace-Lorraine, capital of (German) Lorraine, on the Moselle, 99 m. N.W. of Strassburg by rail, and at the radiation of lines to Luxemburg, Coblenz and Novéant, on the French frontier (10½ m. W.). Pop. (1905), 60,396. The general appearance of the town is quaint and irregular, but there are several handsome modern streets. The Moselle, which is here joined by the Seille, flows through it in several arms, and is crossed by fourteen bridges. In the south-west corner of the town is the esplanade, with an equestrian statue of the emperor William I., and monuments to Prince Frederick Charles and Marshal Ney, commanding a fine view of the "pays messin," a fertile plain lying to the south. Of the ten city gates the most interesting are the Porte d'Allemagne, or Deutsche Tor, on the east, a castellated structure erected in 1445 and still bearing traces of the siege by Charles V.; the Porte Serpenoise, or Römer Tor, on the south, and the Porte Française, or Französische Tor, on the west. Among its ecclesiastical edifices (nine Roman Catholic and four Protestant churches) the most noteworthy is the Roman Catholic cathedral, with huge pointed windows, slender columns and numerous flying buttresses, which, begun in the 13th century and consecrated in 1546, belongs to the period of the decadence of the Gothic style. The Gothic churches of St Vincent and St Eucharius, and the handsome Protestant garrison church, completed in 1881, also deserve mention. Among secular buildings the most important are the town-hall, the palace of justice, the theatre, the governor's house, and the various buildings for military purposes. The public library contains 40,000 volumes, including an extensive collection of works relating to the history of Lorraine. In the same building is the museum, which contains a picture gallery, a numismatic cabinet, and a collection of specimens of natural history. Metz also possesses several learned societies, charitable institutions and schools, and a military academy. The cemetery of Chambière contains the graves of 7200 French soldiers who died here in 1870. The chief industries are tanning and the manufacture of weapons, shoes, cloth, hats and artificial flowers. There is a trade in wine, beer, wood and minerals.

As a fortress, Metz has always been of the highest importance, and throughout history down to 1870 it had never succumbed to an enemy, thus earning for itself the name of *La pucelle*. It now ranks with Strassburg as one of the two great bulwarks of the west frontier of Germany. The original town walls were replaced by ramparts in 1550, and the citadel was built a few years later. By 1674 the works had been reconstructed by Vauban. Under Napoleon III. the fortress was strengthened by a circle of detached forts, which, after 1870, were modified and completed by the Germans, who treated the fortress as the principal pivot of offensive operations against France. The plans in FORTIFICATION AND SIEGECRAFT (fig. 43) show Metz as it was about 1900; in the years following a new outer chain of defences was constructed, which extends as far as Thionville on the north side and has its centre in front of Metz on the Gravelotte battleground. The old enceinte (which includes Cormontaingne's forts—Moselle and Bellevroix) is doomed to demolition, and has in part been already removed. The garrison, chiefly composed of the XVI. Army Corps, numbers about 25,000. (See GERMANY: *Army*.)

History.—Metz, the Roman Divodurum, was the chief town of the Mediomatrici, and was also called by the Romans

Mediomatrica, a name from which the present form has been derived by contraction. Caesar describes it as one of the oldest and most important towns in Gaul. The Romans, recognizing its strategical importance, fortified it, and supplied it with water by an imposing aqueduct, the remains of which still exist. Under the Roman emperors Metz was connected by military roads with Toul, Langres, Lyons, Strassburg, Verdun, Reims and Trier. Christianity was introduced in the 3rd century of our era. In the middle of the 5th century the town was plundered by the Huns under Attila; subsequently it came into possession of the Franks, and was made the capital of Austrasia. On the partition of the Carolingian realms in 843 Metz fell to the share of the emperor Lothair I. as the capital of Lorraine. Its bishops, whose creation reaches back to the 4th century, now began to be very powerful. Metz acquired the privileges of a free imperial town in the 13th century, and soon attained great commercial prosperity. Having adopted the reformed doctrines in 1552 and 1553, it fell into the hands of the French through treachery, and was heroically and successfully defended against Charles V. by Francis duke of Guise. It now sank to the level of a French provincial town, and its population dwindled from 60,000 to about 22,000. At the peace of Westphalia in 1648 Metz, with Toul and Verdun, was formally ceded to France, in whose possession it remained for upwards of two centuries. The battles of August 1870, and the investment and capture of the army of Metz which followed, are described below. By the peace of Frankfort on the 10th of May 1871 Metz was again united to the German Empire.

See Westphal, *Geschichte der Stadt Metz* (1875–1877); Georg Lang, *Metz und seine Umgebungen* (1883), the *Statistisch-topographisches Handbuch für Lothringen*; Albers, *Geschichte der Stadt Metz* (Metz, 1902); G. A. Prost, *Études sur l'histoire de Metz* (1897); and Tauber, *Die Schlachtfelder von Metz* (Berlin, 1902). (See also FRANCO-GERMAN WAR: *Bibliography.*)

BATTLES AROUND METZ, IN THE FRANCO-GERMAN WAR, 1870

1. *Colombey-Borny* (*August 14*).—The French army under Marshal Bazaine was in and about Metz. The German I. and II. armies, on the march from the Saar, were heading for the Moselle between Metz and Pont-à-Mousson, and on the morning of the 14th of August the German I. Army (I., VII. and VIII. Corps, under General v. Steinmetz) lay on and east of the French, with outposts well to the front, watching the French camps east of Metz, which were little more than 1 m. to the front. Steinmetz had received from headquarters overnight instructions that on the 14th of August the I. Army would maintain the positions occupied during the 13th, and merely passed on these orders to his corps commanders. In Metz, meanwhile, Bazaine had decided to retreat, and during the morning orders to that effect reached his corps commanders, who commenced preparations for their execution. The 2nd Corps (Frossard) and 6th (Canrobert) began to retire about midday, the 3rd (Lebœuf), 4th (Ladmirault) and Imperial Guard (Bourbaki) were to follow. These preparations being observed, the German outposts got under arms. General von der Goltz, in command of the VII. Corps (7 battalions, 4 squadrons, 2 batteries) hearing from a passing officer that the I. Corps on his right was preparing to attack, and noting personally signs of retreat in the enemy's lines, determined at 3 p.m. to advance his whole command to the ridge between Colombey and Borny (which was still occupied by French outposts), in order to clear up the situation. The ridge was captured with little resistance, but the sound of the firing at once set all the neighbouring troops in motion, and fortunately so, for the French had immediately retaliated on von der Goltz's audacious attack. Between 4 and 6 p.m. there was continuous heavy fighting on the front from Borny to Méy, as both sides brought fresh troops into the field. The convex slopes falling from the Prussian position towards Metz gave plenty of cover to the French, and the setting sun shone full in the faces of the Prussian artillerymen. Thus the Prussian infantry encountered unusually obstinate resistance and the troops engaged rapidly slipped from all superior control. The above front was held by the French 3rd Corps. Shortly before 6.30 the 4th Corps (Ladmirault) suddenly began to deploy on the high ground to the north-west beyond Méy, thus threatening the right flank of the Prussian I. Corps (General v. Manteuffel). To meet this danger Manteuffel was compelled to direct his corps artillery and reserves, which were now rapidly coming up, away from the hard-pressed centre towards the oncoming infantry masses of Ladmirault. These, with the sun now almost at their backs, were shooting better than usual, and Manteuffel was compelled to call on the VIII. Corps for assistance, which its commander, under positive orders from Steinmetz, refused to give. Meanwhile Steinmetz had been sending peremptory orders to the battlefield to stop the battle, but neither of the corps commanders was able to enforce them. Fortunately for the Prussians, Bazaine had issued similar orders to his subordinates, who, having their men better in hand, were able to obey; and as night began to close in the French broke off the action and retired under the guns of the Metz forts, convinced that at last they had "broken the spell" of German success.

Finding that, in spite of his orders, the firing at the front continued increasing in intensity, Steinmetz at length rode to the front himself. Meeting Manteuffel near the Brasserie of Noisseville, he overwhelmed him with reproaches, and at the crisis of this scene the bands struck up "*Heil dir im Siegeskranz*"! In this action the Germans brought 30,500 rifles and 150 guns on to the battlefield only out of more than 100,000 with 300 guns which could have been engaged before darkness. Bazaine actually deployed 50,700 rifles and 206 guns to oppose them. He might, however, had he been so minded, have struck with his whole army—nearly three times this force, and, judging from the course events actually took, we can have little doubt as to the result of such a blow. The losses on either side were in killed and wounded—French about 3600, Germans about 4800.

The chain of causation in this action is particularly worthy of attention: A young reserve officer, seeing some troops of the I. Corps standing to arms, reported to von der Goltz that the corps was standing to arms and about to attack. Von der Goltz thereupon decided to go forward and discover what was actually going on, and this action unchained the whole battle power of all the troops within call. When, on the following morning, Steinmetz reported von der Goltz and the commander of the I. Corps for disobedience, the king thanked Manteuffel warmly for the part he had played, and then turned to the young brigadier who had disobeyed orders and congratulated him on having twice distinguished himself in the first fortnight of the war.

2. *The Battle of Vionville—Mars-la-Tour* (*August 16*).—On the following day (15th) the II. German Army approached the Moselle above and below Pont-à-Mousson, with a view to overtaking and heading off Bazaine in his presumed retreat to the Meuse (see FRANCO-GERMAN WAR). So far, however, from being ahead of the Germans on the road to Verdun, the French were actually, late in the afternoon of the 15th of August, bivouacked on the plateau of Rezonville, and there their outposts were placed, not where they could see the surrounding country, but at the regulation distances of 600 to 1000 paces from the bivouacs. Friendly inhabitants kept Bazaine well informed as to the magnitude of the danger threatening him from the south, and a special telegram from Paris, the true origin of which has never been traced, led him to believe that the I. German Army was crossing the Moselle near Thionville and about to descend on him from the north. This telegram might have exercised the most prejudicial influence on the course of the battle had not Ladmirault (4th Corps), nearer to the seat of the imaginary danger, taken upon himself to disregard the warning transmitted to him by headquarters. At daybreak on the 16th, no Prussians being reported in sight by the outposts, the troops began nonchalantly to prepare for the resumption of the march.

On the Prussian side, von Alvensleben's Corps (III.) shortly after daybreak was moving north-westward from the Moselle in two columns, on the right the 5th division, via Gorze and Flavigny on Vionville, on the left the 6th division with corps artillery by Arnaville on Mars-la-Tour, von Alvensleben himself riding a little in advance between the two. The 6th cavalry division was ordered to precede the right column and scout towards Rezonville. No one was aware of the dangerous proximity of the French army.

About 9 a.m. the 5th cavalry division, reinforced by two horse artillery batteries (flank guard of the X. Corps from Thiancourt), and accompanied by von Caprivi (chief of staff, X. Corps, and afterwards chancellor of the German Empire), were trotting up the western slopes of the ridge which runs between Tronville and Vionville. Reaching its summit they suddenly found themselves in face of at least 40,000 French troops, which were not under arms, but busied with miscellaneous camp duties. The temptation proved too great for the artillery, who promptly fired into the midst of the cavalry camp (Forton's division) which lay nearest to them. The momentary result was a wild panic, especially among the horses; but this panic gave the alarm to the infantry all along the road, and these (Frossard's 2nd Corps) at once stood to arms and moved forward, deployed for attack—one division to the west, another division, from Rezonville, to the south. The latter almost at once encountered the heads of the 6th cavalry division, at that moment just clearing the defile leading up to the Rezonville plateau from Gorze. The Prussian cavalry promptly bore away to cover to the westward, and reported what they had seen to superior authority, but not to the advanced guard of the 5th infantry division, which, emerging in its turn from the defile, ran right against the deployed French infantry moving to meet them. So sudden was the collision that the Prussian advanced guard battery had to fire case to clear its own front.

Emery Walker sc.

Meanwhile von Alvensleben himself, riding on the field track from Gorze towards Vionville, whence he could overlook the whole country to the north and west, had met von Rheinbaben (commanding the 5th cavalry division) and had seen the surprise of the French camps. The sound of the heavy firing coming from the eastward convinced him of what had been gradually dawning on him—that with barely 30,000 men he was in the presence of the whole French army, whose attitude at this moment sufficiently indicated their determination to fight.

In a few moments his decision was taken. Calling on the X. Corps, away to the south-westward, for support, he determined to screen his own weakness by a vigorous attack. By universal consent this is approved as the boldest resolution arrived at by an independent commander throughout the war. Orders were forthwith despatched to the 6th infantry division, at that moment between Puxieux and Tronville, to wheel in to their right and attack, and, their movement being still hidden from the enemy, these troops were formally drawn up for action and sent forward as a whole. The French meanwhile had occupied Vionville and Flavigny, and other troops were moving down the slopes from Rezonville to their support, but the united onset of this whole German division overbore all resistance, and the French began to retire eastward, suffering terribly from the shell fire of the Prussian batteries.

Marshal Bazaine had meanwhile arrived on the scene, and ordering forward fresh troops to relieve (not to reinforce) those already engaged, he rode forward with a horse artillery battery to watch the operations. The retreating French troops belonged to Frossard's command, and as they were in considerable confusion Frossard called on du Preuil's brigade of the imperial guard cavalry to charge. He gave no objective, and when the brigadier pointed out that the enemy was still beyond the striking radius of his horses, Frossard reiterated the order, which was obeyed to the letter.

The result was disastrous. The Prussians, having seen the cavalry whilst yet at a distance, ceased firing, formed their skirmishers into groups, and the closed supports standing in deployed lines, two deep, shattered the cavalry with volleys and file-firing, as with blown and exhausted horses they endeavoured to close with their adversaries. When in addition two hussar regiments struck them in flank they were driven back in wild disorder upon Rezonville. In the dust and confusion of the charge a group of the hussars approached Bazaine and his horse artillery battery, and almost carried off the marshal.

Alvensleben, mistaking the withdrawal of the French for the beginning of a retreat, had meanwhile sent orders to the 6th cavalry division to charge in pursuit towards Rezonville; but before it could reach the field the French relieving troops had forced their way through the stragglers and showed such a bold front to the Prussian horsemen that an attack held no promise of success, more especially since they had lost their intervals in their advance and had no room for a proper deployment. To steady the young soldiers, the cavalry commander (Carl von Schmidt) halted his men, made them correct their intervals and dressing as in peace, though under a heavy fire from the French infantry, and then withdrew them behind the cover of the nearest hill at a walk.

The threat of the charge had, however, induced caution on the French side, and for about two hours there was a lull in the fighting, which the Prussians utilized on their right in bringing up reinforcements through the Bois des Ognons. On their left, however, no fresh troops were as yet available, and on being informed, about 2·30 p.m., that French cavalry seemed to be about to charge the exhausted 6th division, Alvensleben ordered Bredow's cavalry brigade to charge, and if necessary to sacrifice itself, to save the infantry. Bredow's command (six squadrons of the 16th Ulans and 7th Cuirassiers) was at that moment drawn up under cover about half a mile west of Vionville, and from its position could see nothing of the events in progress on the battlefield. Nettled by the form in which the order was conveyed to him, Bredow drew his sword and ordered his trumpeter to sound the "trot," the brigade moving off in line of squadron columns at close interval in the direction in which they happened at the moment to be facing. Near Vionville they took ground to their left, opening to full intervals as they did so, and then ascended the gentle incline which still hid them from their enemy.

Arrived at the summit, Bredow sounded "line to the front," but at that moment a storm of French bullets swept down on them, and the men, no longer to be restrained, dashed forward, before the line could be completed, almost due east against long lines of infantry and artillery which they now saw for the first time about 1200 yards in front of them.

This distance was covered at the fullest extended speed of the horses, and reaching the infantry they swept over them "like hounds over a fence"—in the words of an eyewitness. So sudden had been their onset that very few were hit until the infantry had been passed; then the latter, recovering from the shock, turned and fired into the cavalry from behind, whilst a whole fresh division of French horsemen charged them in flank. After a desperate mêlée of some minutes, the rally was sounded, and the survivors of the charge, breaking their way a second time through the French infantry, eventually reached the shelter of their own lines, having lost rather more than half their numbers, but having saved the situation momentarily for their own army. Again there was a lull in the operations.

Meanwhile, unknown to Alvensleben, a fresh storm was brewing on his left rear.

Ladmirault, commanding the French 4th Corps had seen, during the afternoon of the 15th, the terrible crowd and confusion prevailing in the defiles leading to Gravelotte, and resolved to disobey his orders and to move direct from his bivouacs by the road from Woippy to St Privat, disregarding altogether the alleged danger from the Prussians supposed to be advancing from Thionville. Thus, about noon on the 16th he reached the high ground between St Privat and Amanvillers, and still without instructions he determined to direct his corps on Bruville and Doncourt, whence he could judge from the drift of the smoke-clouds whether he could fall on the Prussian left.

Much time was lost owing to the heat of the day and the fatigue of the troops, but shortly after 3 p.m. he reached a position north of the Tronville copses whence his guns could fire into the left rear of the long line of Prussian guns (6th division and corps artillery) on the heights above Vionville and Flavigny. Their fire threw the latter into serious confusion and he had already decided to attack with his nearest division (de Cissey) in the direction of the steeple of Vionville, when his attention was caught by the outbreak of heavy firing in the copses below him, and the entry of fresh Prussian guns into action.

This diversion was brought about by the arrival of the corps artillery of the X. Corps and of the 40th brigade, which latter had been at once ordered into the Tronville copses to check portions of Tixier's division of the French 3rd Corps, which under cover of these copses had gradually worked round the Prussian flank. Seeing then that the troops before him could hold their own, Ladmirault continued his preparations for his counterstroke, and Cissey's division had begun to move into its prescribed alignment, facing towards Vionville, when the sudden apparition of a closed mass of Prussian troops detaching itself from the low dust-cloud of a slow-moving infantry column, and forming to the south of Mars-la-Tour, again arrested his attention. Unanimously he and his staff agreed that this fresh enemy could only be the advanced guard of a large Prussian force, possibly, it was suggested, of the crown prince's army, from Alsace and Nancy, and a fresh delay arose while the situation was investigated. Actually this body consisted only of the 38th brigade (von Wedell), forming part of the X. Corps. It had no knowledge of the state of affairs on the battlefield, or in the direction of Bruville, though Prussian cavalry had been observing the approach of Ladmirault's corps for some hours. It was now ordered to deploy and to co-operate with the 40th brigade in an attack on the Tronville copses. This meanwhile had been delivered, and had more or less failed.

The deployment completed, about 4 p.m. the 38th brigade began its advance on the north-west corner of the Tronville copses, this direction taking them diagonally across the front of Cissey's division, still out of their sight but moving due south. Hardly had they stepped off when Cissey's first line, catching sight of them, opened a devastating fire upon their left flank, and to meet this fresh danger the Prussians endeavoured to change front half-left whilst still on the move. Without pausing to fire, the men raced onward, but the French striking their outer wing rolled up the whole line in succession, the actual collision occurring in and near the Bruville ravine, a deep-cut natural trench which, starting from the Tronville copses, here intersects the plateau from west to east. Against the weight of French numbers, nearly three to one, the Prussians were unable to stand, and presently they broke and drifted backwards, completely routed. Then the 1st Guard Dragoons (since known as Queen Victoria's regiment), after a brilliant manœuvre under heavy fire, to get into the best position for delivering a charge, rode down the whole French line of pursuers from left to right, and by their heroic self-sacrifice relieved the remnants of the infantry from further pursuit.

This was the scene which for the moment held the attention of Prince Frederick Charles when at length he reached the battlefield from Pont-à-Mousson. All along the rest of the line the Prussians were still holding their own, and on the extreme right fresh troops from the IX. Corps were streaming up through the woods against the French left wing. But on the left there was every sign of incipient disaster, and to avert this only the cavalry were at hand. Sending, therefore, hasty orders to the 5th and 6th cavalry divisions to concentrate to the west of Mars-la-Tour, the prince ordered them from there to sweep round on the right rear of the French army. The same idea had, however, occurred to Ladmirault, and he had called on the two nearest French cavalry divisions to put it into execution, and as the Prussians began to reach the plateau west of Mars-la-Tour and the Yron brook from the south, the French were deploying across it some two thousand yards to the north.

Then followed a duel—the one great cavalry duel of the war—between upwards of two thousand horsemen a side. But it was delivered by both sides in a series of regimental charges, and in result was singularly indecisive. For about half an hour great crowds of riders, hidden by dense clouds of dust, drifted aimlessly about the plain, till at length the charge of a single squadron of the Oldenburg Dragoons (who had joined in on their own initiative) delivered on the outer French flank, brought the whole mass into motion north-eastward, and, both sides sounding the rally, the engagement gradually ceased.

It was now about 7 p.m. and night was coming on. Seeing the dust-clouds drifting away northward, and noting the lethargy which seemed to have settled over the whole French line, Prince Frederick Charles decided to assert his own independent will to conquer by a final assault along his whole front. Guns, cavalry, infantry, everything that could still stand were to take part in it. Weary as they all were, his indomitable will put fresh life into the whole army. With drums beating and colours flying, every unit within call went forward for the final effort. It was almost dark when the Prussians approached the French position between Rezonville and the woods to the northward, and the troops soon lost direction in the smoke and became involved in the direst confusion; the firing again blazed out for a few moments, only to die away as utter exhaustion at length put an end to the Prussian advance. Then the wearied troops, for the most part, lay down and slept in the positions they had reached.

Thus closed the hardest fought battle of the Franco-German War. From 9 a.m. to 3 p.m. only 23,700 rifles, 8100 sabres and 126 guns had been brought into action by the Germans against 59,100 rifles, 6700 sabres, and 300 guns on the French side, and even at the close of the day the former had only deployed 47,100 rifles, 8300 sabres and 222 guns against 83,000 rifles, 8000 sabres and 432 guns including 24 mitrailleuses. The chief characteristic of the day's fighting was the terrible effectiveness of the Prussian artillery, which was handled in masses and not, as on the French side, by batteries. The manœuvring power of the latter attracted the admiration of the Germans, but arriving singly on the field they were generally reduced to silence in a few minutes. Deprived of their support, not all the gallantry of the French infantry could avail anything. Again and again, particularly on their left wing, they chased the German infantry before them, but the moment the retreat of the latter downhill uncovered the pursuing French to the Prussian guns, a tornado of shells shattered their order and compelled them to retreat. Though the cavalry were freely engaged, the training of both was so far beneath the standard of the present day that the most that can be credited to them in respect of results is that they from time to time averted imminent disaster, but failed altogether to achieve such a decision as was well within their potential capacities.

3. *Gravelotte—St Privat* (*August 18*).—The position on to which the French army fell back from the field of Vionville is formed by a ridge some six miles long running from Rozerieulles almost due north to Roncourt, a little village overhanging the steep and wooded banks of the Orne, and connected with the general plateau between the Meuse and Moselle by a gentle saddle running from about Amanvillers nearly due west through the Bois de la Cusse towards Doncourt. North of this saddle the slopes show a slight concavity, but are passable by troops of all arms in close order. To the south the rivulet of the Mance soon forms a formidable obstacle as its bed cuts its way through the sandstone. Scrub and woods with dense undergrowth line both its banks, and, except by the great chaussée from Metz to Verdun, access to the French side becomes impossible to troops in ordered bodies.

It does not appear that the position had been systematically examined, or apportioned to the several corps in accordance with any predetermined plan. The army merely swung backwards, pivoting on its left wing, the corps preserving their relative order as it had been on the 16th, with the exception that the Imperial Guard was withdrawn to the spur on which Fort Plappeville stands, and the 6th Corps (Marshal Canrobert) crossed the line of march of the 3rd and 4th Corps in order to gain St Privat la Montagne. No lines of march were assigned to the several units, consequently the confusion became so great that though the distance to be traversed in no case exceeded six miles, only the right wing and centre reached their destinations as night was falling. Many of them had so little idea of the general situation that they actually placed outposts to the north and east, whilst the whole of the enemy's army lay to the south and west. No attempt was made to entrench the position systematically, but on the left the 2nd and 3rd Corps made some disconnected shelter trenches and gun-pits, while the 4th Corps in the centre began to improve available cover about an hour before the battle began, and the 6th corps on the right, not yet having received any entrenching tools, could do no more than improvise a few loopholes in the walls of the villages of St Privat and Roncourt with such tools as the sappers could obtain from the inhabitants.

Fortunately for the French the Germans were too exhausted by the battle of the 16th to attempt to interfere with these movements. At daybreak on the morning of the 18th the royal headquarters (which now for the first time arrived at the front) still had no certain knowledge as to whether the French main army was in retreat—covered by the force which they could see on the high ground north of the Metz road—or whether they had taken up a position in order to fight.

Hence the orders issued overnight on the presumption that the main force of the French was retreating to the north and west were allowed to stand, and the whole II. Army (Prince Frederick Charles) moved off in échelon from left to right, the I. army under Steinmetz, consisting for the day of the I., II. and VII. Corps, being left in observation of the troops visible on their front and of the garrison of Metz itself. The I. Corps was kept back beyond the Moselle on the east side of Metz, the II. was not due to arrive at Rezonville before 4 p.m., hence the VII. only was immediately available if the enemy counter-attacked. But Steinmetz had not ordered, nor had von Zastrow, the corps commander, undertaken, any preparations to meet an emergency. About 10 a.m. the corps had reached the following positions:

VIII. Corps, Rezonville; XI. near St Marcel; Guard approaching Donçourt; XII. towards Jarny; the III. and X., which had been so heavily engaged on the 16th, still in their bivouacs preparing to move. The cavalry of the Saxons had established the fact that the French had not retreated northward, but though scouts from the Guard had already seen the enemy on the heights of St Privat, this information had not yet reached headquarters, nor had it been transmitted to the IX. Corps, which it most closely concerned.

Shortly after 10 a.m. Moltke, still under the impression that the French right extended no farther than La Folie (2 m. north of the Metz road), determined to attack with the IX. and VIII. Corps whilst the Guard executed a turning movement via Habonville against the French right. The IX. Corps was to engage, but not to push its attack home until the Guard could co-operate. The XII. Corps was left to its own devices, but fortunately the crown prince of Saxony, who commanded it, had ridden forward and, seeing the French in force towards Roncourt, had issued orders which in the event proved decisive.

In pursuance of his instructions von Manstein, commanding the IX. Corps, set his two divisions in motion towards La Folie and the Bois de la Cusse, and advanced to reconnoitre the French position. From the eastern edge of the above-named copses he suddenly descried the camp of a whole French Corps (the 4th), evidently ignorant of their danger, on the slopes trending westward from Amanvillers. Unmindful of the experience of the 16th, he decided to execute an artillery surprise on a grand scale, and sent orders to his corps artillery to come into action on the long spur overlooking the French camps from the westward. At noon, just as the French infantry were falling in for midday roll-call, sufficient guns were in position, and suddenly opened fire. But the effect was disappointing. The French infantry ran to their arms, piled along the front of their positions, and moved forward to attack, covering their advance by a hail of bullets. Simultaneously the French artillery also took up the challenge, and from the heights near St Privat the 6th Corps, whose presence had been unsuspected by the Prussians, joined in the fight.

In a few minutes the batteries on the extreme Prussian left were completely overwhelmed, and suddenly dense lines of French skirmishers emerged from a fold in the ground upon their flank and front, and the gunners were compelled to resort to case-shot, so imminent was their danger. But at this critical moment the leading companies of the Hessian infantry arrived, re-established the equilibrium (though not before four Prussian batteries had been temporarily overrun by the enemy), and a most obstinate fight ensued.

Prince Frederick Charles now rode forward to a point north-east of Vernéville, whence the southern boundary of St Privat could be seen. But the northern side of the village and the country towards Roncourt was hidden from his view by the high poplars bordering the Metz-Briey road. Seeing the Hessians hard pressed, he now brought forward the 2nd division of the Guard to their assistance, sending in the 3rd brigade immediately, and holding the 4th brigade in reserve. The 1st division, warned by their own scouts that French troops were in Ste Marie, deployed to attack this village, and were assisted in their endeavour by a brigade of Saxons detached by the crown prince of Saxony, who from his position could see behind the poplar screen that limited the view of the commander-in-chief. Hence he was already aware that the French position extended to Roncourt at least, and had despatched a whole division down the valley of the Orne to outflank them. No news of this movement, however, appears to have reached Prince Frederick Charles.

The French troops in Ste Marie were only an outpost of the 6th corps, and seeing themselves outnumbered, they withdrew about 2.30, the Prussians rushing the village immediately afterwards. Considerable confusion arose from the convergence of these three brigades upon one village, and more than an hour passed before the troops could be disentangled and massed for further operations. The leaders of the two Guard brigades, still ignorant of the extent of the French position, rallied their men on the main bodies of their commands (which had not been engaged) and then lay down facing exactly as they had done when brought forward to the attack. Thus the 1st brigade lay, facing about east-south-east, south of the chaussée and some five hundred yards west of the village. The 2nd brigade lay south-west of the village about three hundred yards away from it and facing nearly north-east.

The Saxons were on the left rear of the 1st brigade, but took longer to recover themselves than the Guards. With the Hessians and the IX. Corps the action still dragged; the 3rd brigade of the Guards had become involved in the fight, and notwithstanding the arrival of the corps artillery of the III. Corps in the centre the situation was still critical. From the south also came the thunder of guns and no encouraging news from that quarter had as yet reached the prince's headquarters.

About 4.30 p.m. the prince therefore had to consider how long it would take to obtain a decision. To postpone it till the morrow seemed undesirable: to achieve it before nightfall was only possible at the cost of immediate effort.

He therefore decided to assault St Privat with all the Guards available, and called up the III., X. and Saxons to assist them.

The 4th brigade of the Guards now received their orders to attack Jérusalem (a hamlet a little south of St Privat), and the 1st division was ordered to assault St Privat itself.

Von Pape, commanding the latter division, pointed out that no artillery force adequate to prepare the way for him was as yet on the ground, and that the Saxons were still a long way to the rear. But his orders were imperative, and the 4th brigade was already moving off and had to be supported at any cost. Actually all available batteries had already been sent for and were trotting forward from every quarter towards the objective. He accordingly transmitted his orders, and the 2nd brigade was the first to attempt their execution. It had to wheel half-right in mass to bring it in the required direction, and then to advance till its rear was clear of the obstruction formed by the gardens of St Marie. By the time (5.30) it had sufficiently cleared this village it became apparent that the 4th brigade in its extension for attack would overlap the front assigned to the 2nd, hence a further (half-left) wheel, still in mass, had to be undertaken before room for deployment could be obtained. Almost as the commands were given, the French suddenly opened an overwhelming long-range fire and their bullets swept like hail through the crowded mass of the German troops. Nevertheless the wheel was effected, the fresh direction taken, the troops extended for attack, and then the whole brigade dashed towards the houses assigned them as their objective. Meanwhile the 1st brigade had moved round the north of the village and carried out its extension without serious hindrance. But emerging from the hollow running north from St Marie, they came under a heavy fire not only from St Privat but also from Roncourt, which latter village they now saw for the first time. Instinctively a portion of their line worked to the left to face this new menace, and the front thus became dangerously extended. They were, however, now abreast of the 2nd brigade, and the whole line raced forward to reach the effective range of their very inferior weapons, which were about equal at 200 yds. to the French rifle at 600. But the losses of the 2nd brigade, particularly in officers, had been too heavy, and the rush died out whilst still 500 yds. from the two villages.

It was now about 6 p.m. and a long pause ensued, while the 220 guns, which by degrees had unlimbered behind them, brought St Privat and Roncourt under fire. About 7 p.m. the Saxon turning-movement took effect; their infantry from the Orne valley attacked Roncourt from the north, and about 7.15 the village was carried.

Neither Prince Frederick Charles nor the troops in the fighting-line could see what had taken place; but the former seeing other Saxons moving towards Montois and the masses of the III. and X. Corps approaching, whilst the rain of shells into St Privat exceeded anything hitherto seen on any battlefield, decided to call on the whole of his force to attack. He was in the act of issuing his orders when a psychological wave swept through the fighting-line, and the men rose and rushed the village at the point of the bayonet. It was now about eight o'clock, and the light was rapidly failing.

The French artillery had already evaded the coming blow, and had changed position, "right back," to cover the flank of the rest of the army, and the Prussian and Saxon artillery trotting forward conformed to this new front, their shells sweeping the ground for 2000 yds. to the south of Amanvillers. The confusion in and around St Privat, where troops from four several corps were all intermingled, became so extreme that no further infantry-advance could be attempted; so under cover of the fierce artillery duel the remnants of the unfortunate 6th corps drifted away towards Metz down the many ravines leading into the river valley. The "annihilation" of the Guard at St Privat has become historic. Yet, heavy as were the losses of the 1st Guard division they were not excessive compared to those previously endured. In round numbers one-third of their effectives had fallen—most of them in the first great rush forward at 5.30 p.m.; but actually they had been more or less under fire since about 2 p.m., and many were hit by French shells plunging into the turmoil about St Privat from 8 to 10 p.m. But the legend cannot be justified when the facts are compared with the slaughter of the Seven Years' War, of Napoleon's battles, the Crimea, and the American Civil War, or with the horrible punishment of von Wedell's brigade (38th) only two days before.

It is now time to return to the southern theatre of the battlefield, where an entirely independent engagement had been raging all the afternoon. Von Goeben with the VIII. Corps was standing massed about Rezonville when von Manstein's guns opposite Amanvillers suddenly made themselves heard. Wheeling his corps to face the French to the eastward he immediately sent forward his artillery and prepared to support his comrade. Von Zastrow with the VII. Corps followed his example. Both corps took as their primary objective the farms of St Hubert and Point du Jour, standing just above the defile made by the Verdun-Metz road where it climbs out of the Mance ravine towards the French position. About 3·30 p.m. St Hubert was carried by a confused mass of some 49 companies, and von Steinmetz, believing the main French position to have been pierced, ordered the 4th cavalry division to cross the ravine by the chaussée and pursue. Simultaneously von Zastrow, under the same impression, had ordered his corps artillery to advance by the same road, and von Goeben, thinking his troops in front required support, had sent forward an infantry brigade by the same line of road.

Presently all these columns converged upon the defile and a hopeless entanglement ensued. Three batteries succeeded in struggling through the mass, and, in coming into action, their left resting on St Hubert. But the remainder of the troops had to be withdrawn, and confusion breaking out in their rear, exposed to all the random bullets and shells of the French, a panic ensued, thousands of men breaking away and flying in wildest confusion through Gravelotte towards the west. Hardly had they melted away when the French made a most brilliant counter-attack from their main position between the farms of Leipzig and Moscow. This was stopped almost entirely by the Prussian artillery fire; but the news of its coming spread through the stragglers in the ravine south of the great road, and a wave of panic again swept through the mass, many thousands bolting right upon the front of their own batteries, thus masking their fire at the most critical moment, and something like a crisis in the battle arose. Fortunately the II. Corps was now rapidly approaching (about 6 p.m.), and the king, against Moltke's advice, now ordered von Steinmetz (to whom the II. Corps had been allotted for the day) to attack again with all his forces. Meanwhile a third panic broke out which delayed the preliminary movements and it was now growing dark in the ravine. At length the II. Corps, together with all of the VII. that could be collected, moved down into the valley. Just as the leading German troops were approaching St Hubert the French again began to fire, their bullets plunging down among the fresh arrivals, who knowing nothing of what had taken place about St Hubert (where the remnant of their own infantry were still offering a desperate resistance) opened fire into the backs of their own men, and a fourth panic began which soon spread to the stragglers crowding the Mance ravine. Fortunately, by the superb gallantry of some of the company officers and men, the new arrivals were induced to recognize their mistake, and by degrees about 10 p.m. the whole of the II. Corps succeeded in reaching the plateau between St Hubert and Point du Jour, where the débris of the VII. and VIII. Corps had gathered. But in the darkness and confusion no forward movement against the French (only 400 yds. to their front) could be initiated, therefore the whole mass passed the night where they stood until daylight disclosed that the French had retreated.

Meanwhile the king, Moltke, and Bismarck, had ridden back behind Gravelotte where they passed two hours of intense anxiety. From the flash of the rifles, it was clear that the French main position was still intact, and as every body of troops within thirty-six hours' call had been engaged there seemed little prospect of renewing the struggle next morning. No news too had come in from Prince Frederick Charles. Ultimately about midnight the welcome tidings of the capture of St Privat arrived, and all anxiety was at an end.

4. *The Investment of Metz* (*Aug. 19–Oct. 14*).—During the night following the battle of Gravelotte the French army withdrew within the line of the forts round Metz. The 6th Corps only was severely shaken, the 4th (the best in the whole army), though it had fought hard twice within forty-eight hours, losing nearly 30% of its strength, was still well in hand, and the 3rd, 2nd and Imperial Guards were almost intact. A fresh issue of ammunition and food was all the men needed to make them a thoroughly efficient fighting force comprising some 100,000 troops capable, with a resolute leader and an efficient staff, of crossing over to the right bank of the Moselle, overrunning the I. German Corps, the only one in their direct path, and then fighting their way across the communications of the II. and III. German Armies until they regained touch with the French railways to the south-west about Troyes.

The mere fact of the effort being made would have given the battle of Gravelotte the moral effect of a victory, and the reaction in the German ranks from the feeling of over-confidence, which had mastered them after the early successes of Spicheren and Woerth, must have had most far-reaching consequences.

Bazaine, however, withdrew entirely under cover of the forts, and set about the reorganization of his troops in the most leisurely manner. The Metz forts, though neither sufficiently armed nor even completely finished in some cases, were nevertheless, with their deep ditches and self-protecting bastion trace, far too formidable for any field army to attempt without the aid of a siege train of some 200 guns, which for the moment were not available. Of this fact the Germans were well aware, and hence they decided from the first to reduce the place by hunger, calculating that with the extra 150,000 men thrown back upon the fortress, its food supplies could not last very long. On the morning of the 19th the German army was far too exhausted for further efforts. Except the I. Corps, which had been summoned overnight from its position about Courcelles towards the battlefield of Gravelotte and had almost reached the Moselle before this move could be counterordered, the remainder kept their places of the previous night, only following the French retreat with a screen of outposts. They were sufficiently occupied in collecting the wounded and clearing up the confusion resulting from an accumulation of trains and transport in the defiles of Gorze and about Novéaut. No eastward movement could have taken place that day. In the course of the afternoon of the 19th the royal headquarters, creating a new army under the crown prince of Saxony (Guard, IV. and XII. (Saxons) Corps) for field operations towards the Meuse, assigned the remainder of the II. Army, and the whole of the I., to Prince Frederick Charles as commander-in-chief of the army of investment.[1] This brought the strength of his command up to eight corps, numbering some 220,000 men; an enormous mass to feed in a district swept bare of supplies by the operations of the preceding week, and with only one railway line, terminating at Courcelles, to depend upon.

For the moment the chief care of the Prince was to guard against an attempt of the French army to break out to the westward. The I. Army Corps with Kummer's Landwehr division (which arrived during the night of the 19th–20th of August) were to occupy a position to cover the rail head at Courcelles–Rémilly, and the remainder were disposed in the following order: The X. Corps was on the north, with a bridge head at Hauconcourt-sur-Moselle, the II., VIII. and VII. along the eastern slopes overlooking the Moselle valley, the latter having also a fortified bridge head at Ars-sur-Moselle. The III. and IX. were cantoned almost on the battlefield of the 18th, between Caulre Farm and Roncourt, ready to move off to the left and support the X. Corps in the event of an attempt on the part of the French to break out towards Thionville.

The positions were fortified with a light outpost line, behind which was drawn a main position on which every art of the engineer was expended. Ample arrangements were made for obtaining and circulating intelligence, and all lateral communications were improved and supplemented to the utmost. A light field-railway from Rémilly to Pont à Mousson (14 m.) was also put in hand, but progress on this was very slow. The water-supply of the town was promptly interrupted, but the river water was quite drinkable.

Meanwhile, the French in Metz had been diligently at work. There was no real deficiency of ammunition and stores in the fortress, and provisions for forty days were reported in hand. Bazaine was still in communication with the outside world, though return messages came in sparingly. On the afternoon of the 25th he decided to break out to the northward by the right bank of the river, and orders to this effect were duly issued. Many delays arose in their execution, and it was not till 2 p.m. on the 26th that the troops were formed up ready for action. But at the last moment the marshal wavered. Calling a council of war on the heights of Fort St Julien, he asked the opinion of his subordinates, who were unanimously against the proposed sortie, principally because the artillery "had only ammunition enough for a *single* battle!" Besides, the Germans had long since become aware of the movement in progress, and all chance of surprise was past. It was also raining very heavily. Accordingly the scheme was abandoned.

On the 29th of August Bazaine received a despatch, dated the 27th, from MacMahon, according to which his army should have been at Stenay on the Meuse and farther to the south by the 30th. The marshal accordingly determined to renew the attempt of the 26th, and orders—almost a repetition of those of the previous occasion—were issued.

At this moment (Aug. 31) the positions of von Manteuffel's command (I. Corps and 3rd Landwehr division) were most dangerously extended, and a surprise at daybreak might have had far-reaching results. But the habit of excessive bugling and band-playing betrayed the French design even before daybreak. Not until 1.30 p.m. was the concentration completed, and Bazaine again assembled his commanding officers to give them their final instructions. This time he adhered to his decision, and about 4 p.m. the attack opened (battle of Servigny or Noisseville); but his opportunity had been allowed to slip, and though his first onset overwhelmed the German outposts, their main line held good, and masses of guns unlimbering over a front of some 4 m. rendered all further attempts to break the German cordon abortive. Firing only ceased as darkness fell, and next morning the fighting was again renewed. But the whole French army was disheartened. It was obvious that what they had failed to do by surprise was hopeless now that twenty-four hours had been given in which the Germans could make counter-preparations. Therefore about noon a general retirement under the guns of the forts took place, and the last serious hope of the French army had vanished. Some 120,000 men with 528 guns had been engaged against 60,000 Germans with 222 guns, and had been beaten off with a loss of 3500 men. The Germans had lost about 3000.

The investment now resumed its regular course. The Germans, secure in the strength of their position on the left bank of the Moselle, drew more troops over to the right, and added to their defences and communications. The idea was even mooted of damming up the river near Hauconcourt, and thus flooding out the whole of the civil population of Metz; but expert civil engineers, who were sent for from Germany, reported against the proposal.

As time wore on the conditions in Metz and the surrounding camps became deplorable. The hospitals and private houses had been crowded with wounded from the first, and now, owing to the persistent wet weather, smallpox and dysentery became epidemic. Towards the close of September rations had to be reduced, and the troops began slaughtering the cavalry horses for food. Probably to cheer the men by a semblance of activity, Marshal Bazaine attempted a sortie on a large scale on the 1st of October in the direction of Ladorchamps, and fighting continued into the 2nd, but without prospect of success, and the profound depression following on defeat sent up the sick list rapidly. One other sortie towards Noisseville followed on the 7th, the alleged reason for which was the hope of obtaining provisions in the neighbouring villages. But it was beaten off with the utmost ease by the investing troops, who were well fed and cared for; and as by this time even the gun-teams had followed the cavalry horses to the slaughter-house, the French army as an army—*i.e.* a combination of the three arms—had ceased to exist. On the recognition of this fact negotiations for the capitulation of Metz were begun on the 13th of October, and on the 14th the Army of the Rhine surrendered. Had it held out even forty-eight hours longer events before Paris and Orleans might have taken a different turn.

The investment of Metz had lasted 54 days, and the death-roll of the civil population had risen to 3587 against 1200 in the corresponding period of a normal year. The army itself had only lost from sickness 2600 men, or barely 2% of its full effective. (F. N. M.)

MEUDON, a town of northern France, in the department of Seine-et-Oise, 6 m. E. of Versailles by rail and about 2½ m. S.W. of Paris. Pop. (1906), 9597. The remains of a castle (17th century) burned during the siege of Paris in 1871 have since been adapted as an observatory. Its terrace commands a fine view of Paris. The handsome Galliera Institutions, on the hill of Fleury, were founded by the duchess of Galliera for the reception of aged persons and orphans. The buildings were completed in 1885, at a cost of £560,000. The town has a monument of Rabelais, who was curé there in 1553, and manufactures munitions of war for the artillery, and in the neighbouring park of Chalais is the Government military ballooning establishment. In the 16th century the cardinal, Charles of Lorraine, built at Meudon a magnificent château, which was destroyed in 1803. The present remains belong to a building erected by the dauphin, son of Louis XIV. The wood of Meudon lies for the most part to the west of the town.

MEULEN, ANTONY FRANCIS VAN DER (1634–1690), Flemish painter, born in Brussels, was called to Paris about 1666 by Colbert, at the instance of Le Brun, to fill the post of battle painter to Louis XIV. His paintings during the campaigns of Flanders (1667) so delighted Louis that from that date Van der Meulen was ordered to accompany him in all his expeditions. In 1673 he was received into the French Academy, attained the grade of councillor in 1681, and died full of honours in Paris in 1690. He is best represented by the series of twenty-three paintings, mostly executed for Louis XIV., now in the Louvre. The show that he always retained his Flemish predilections in point of colour, although his style was modified by that of the French school.

---

[1] Steinmetz was shortly afterwards relieved of his command and returned to Germany.

MEUNIER, CONSTANTIN (1831–1905), Belgian painter and sculptor, was born at Etterbeek, Brussels. His first exhibit was a plaster sketch, "The Garland," at the Brussels Salon in 1851. Soon afterwards, on the advice of the painter Charles de Groux, he abandoned the chisel for the brush. His first important painting, "The Salle St Roch" (1857), was followed by a series of paintings including "A Trappist Funeral" (1860), "Trappists Ploughing" (1863), in collaboration with Alfred Verwée, "Divine Service at the Monastery of La Trappe" (1871) and episodes of the Peasants' War (1878). About 1880 he was commissioned to illustrate those parts of Camille Lemonnier's description of Belgium in *Le Tour du monde* which referred to miners and factory-workers, and produced "In the Factory," "Smithery at Cockerill's," "Melting Steel at the Factory at Seraing" (1882), "Returning from the Pit," and "The Broken Crucible" (1884). In 1882 he was employed by the government to copy Pedro Campana's "Descent from the Cross" at Seville, and in Spain he painted such characteristic pictures as "The Café Concert," "Procession on Good Friday," and "The Tobacco Factory at Seville" (Brussels Gallery). On his return to Belgium he was appointed professor at the Louvain Academy of Fine Arts. In 1885 he returned to statuary and produced "The Puddler," "The Hammerer" (1886), "Firedamp" (1889, Brussels Gallery), "Ecce Homo" (1891), "The Old Mine-Horse" (1891), "The Mower" (1892), "The Glebe" (1892), the monument to Father Damien at Louvain (1893), "Puddler at the Furnace" (1893), the scheme of decoration for the Botanic Garden at Brussels in collaboration with the sculptor Charles van der Stappen (1893), "The Horse at the Pond," in the square in the north-east quarter of Brussels, and two unfinished works, the "Monument to Labour" and the Zola monument, in collaboration with the French sculptor Charpentier. The "Monument to Labour," which was acquired by the State for the Brussels Gallery, comprises four stone bas-reliefs, "Industry," "The Mine," "Harvest," and the "Harbour"; four bronze statues, "The Sower," "The Smith," "The Miner," and the "Ancestor"; and a bronze group, "Maternity," Meunier died at Brussels on the 4th of April 1905.

MEURICE, FRANÇOIS PAUL (1818–1905), French dramatist, was born in Paris on the 7th of February 1818. In 1848 he became the editor of the *Événement*, founded by Victor Hugo, and in 1869 he was one of the promoters of the *Rappel*, a journal on similar lines. He was the literary executor of Victor Hugo, and edited his works (1880–1885). In collaboration with Auguste Vacquerie and Théophile Gautier, he produced *Falstaff* (1842), a play in imitation of Shakespeare, and in 1843 an imitation of the *Antigone*; and with Alexandre Dumas a *Hamlet* (1847). He also wrote *Benvenuto Cellini* (1852), *Schamyl* (1854), *Struensée* (1893), and dramatic versions of *Les Misérables* (1878), *Notre Dame de Paris* (1876), *Quatre-vingt-treize* (1881). He died on the 12th of December 1905.

MEURSIUS [JOHANNES VAN MEURS] (1579–1639), Dutch classical scholar and antiquary, was born at Loosduinen, near the Hague. He was extremely precocious, and at the age of sixteen produced a commentary on the *Cassandra* of Lycophron. In 1610 he was appointed professor of Greek and history at Leiden, and in the following year historiographer to the states-general. In consequence of the disturbed state of his country he welcomed the offer (1625) of Christian IV. of Denmark to become professor of history and politics at Sorö, in Zealand, combined with the office of historiographer royal. He died at Sorö on the 20th of September 1639. Meursius was the author of classical editions and treatises, many of which are printed in J. F. Gronovius's *Thesaurus antiquitatum graecarum.* Their lack of arrangement detracts from their value, but they are a storehouse of information, and Meursius does not deserve the epithets of "pedant" and "ignoramus" which Scaliger applied to him. Meursius also wrote on the troubles in the Netherlands and the history of Denmark.

Complete edition of his works by J. Lami (1741–1763). See Van der Aa's *Biographisch Woordenboek der Nederlanden* (1869), and J. E. Sandys, *Hist. of Class. Scholarship* (1908), ii. 311.

MEURTHE-ET-MOSELLE, a department of north-eastern France, formed in 1871 out of those parts of the old departments of Meurthe and Moselle which continued French. Before 1790 it belonged to Lorraine, or to one or other of the bishoprics of Toul, Metz and Verdun. Pop. (1906), 517,508. Area 2038 sq. m. It is bounded E. by Lorraine, N. by Belgium and the grand-duchy of Luxemburg, W. by the department of Meuse, and S. by that of Vosges. Meurthe-et-Moselle is of a hilly character, the highest elevation, the Grand Rougimont (2041 ft.), being in the Vosges. The valley of the Moselle runs through it from south to north. Extensive forests, the chief of which is the Forest of Haye, are found in the south-western region. Only a small part of the drainage of Meurthe-et-Moselle flows into the Meuse, by far the greater part reaching the Rhine by way of the Moselle. The principal affluents of the Moselle are the Madon and the Orne on the left, and on the right, besides the Meurthe, the Seille, which in one part of its course forms the boundary of Alsace-Lorraine. The principal tributary of the Meuse within the department is the Chiers. Climatologically Meurthe-et-Moselle belongs to the Vosgian region, and has hot summers and severe winters. Its mean annual temperature is between 48° and 49° F., being 2° lower than that of Paris (which has the same latitude). The annual rainfall averages between 28 and 32 in. The department possesses much fertile land, the chief crops being cereals and potatoes, together with clover, mangel-wurzels, tobacco, hops and beetroot. The vine is also cultivated, its best products being those of the Toul district. The most common fruit trees are the pear, the apple, the walnut, the cherry and the plum. Of forest trees the oak and the wych-elm are most frequent in the west of the department, the beech and the fir in the Vosges. The French school of forestry has its seat at Nancy. The salt-workings (the chief of which lie between Nancy and St Nicolas,) and the iron-mines (round Nancy and Longwy) of Meurthe-et-Moselle are the most productive in France. Other important industries are the manufacture of boots and shoes, straw and felt hats, pottery, and tanning and brewing (at Tantonville). Cotton and wool spinning, and the manufacture of cotton goods, hosiery, embroidery, chemicals (at Dombasle, close to Nancy), soap, tobacco, matches, crystal (at Baccarat, which has a population of 5617), mirrors (Cirey), glass, army clothing and paper may also be mentioned. The department is served by the Eastern railway, the chief line being that from Paris to Strassburg through Nancy. The main waterway is formed by the canal between the Marne and the Rhine. This canal communicates with the Moselle, which is navigable from Frouard downwards, and with the Eastern canal, which unites the Meuse and the Moselle with the Saône and the Rhone. The department constitutes the diocese of Nancy, has its court of appeal at Nancy, and forms a part of the district of the VI. army corps (Châlons-sur-Marne), and of the académie (educational division) of Nancy. There are 4 arrondissements (Nancy, Briey, Lunéville and Toul), 29 cantons and 598 communes. The principal towns of the department are Nancy, the capital, Lunéville, Toul, Longwy, Pont-à-Mousson and St Nicolas. Other places of interest are Prény, with ruins of an important stronghold (12th and 13th centuries) of the dukes of Lorraine; and Vaudémont, seat of a famous countship, with ruins of a stronghold of the 12th and 14th centuries.

MEUSE (Flem. *Maes*, Du. *Maas*), a river rising at Pouilly, in the department of Haute Marne, France. After passing through a great part of Belgium and Holland it flows into the Waal channel of the Rhine at Fort Loevenstein. A few miles below Gorinchem the Meuse, or Waal as it is then called, divides into two branches. The northern flows almost due west, and joins the Lek (Rhine) above Rotterdam, and enters the North Sea at the Hook of Holland. Ocean-going steamers for Rotterdam use, however, the New Waterway (*Nieuwe Waterweg*), a little north of the Meuse. The southern branch turns south, crosses the marsh of Biesbosch by the canalized channel of New Merwede, enters the Hollandsch Diep, and reaches the sea by the arms called Haringvliet and Krammer.

The length of the Meuse is nearly 560 m., of which 360 are navigable, and probably its traffic is only exceeded by that of the Rhine. Near Bazeilles it disappears under ground for a distance of over 3 m. The Chiers, the Semois, the Lesse, the Sambre, the Ourthe and the Roer are its most important tributaries. In Belgium it is canalized between Liége and Vise, and the Dutch are engaged on the same operation below Maestricht. The principal towns on the Meuse are: in France, Verdun, Sêdan, Mézières and Givet; in Belgium, Dinant, Namur, Huy, Liége and Maeseyck; in Holland, Maestricht, Roermond, Venlo, Dordrecht and Rotterdam.

MEUSE, a department of north-eastern France, formed out of a part of Lorraine (portions of the Three Bishoprics, and the Barrois and Clermontais) and Champagne. Pop. (1906), 280,220. Area, 2409 sq. m. It is bounded N. by Belgium and the department of Ardennes, E. by that of Meurthe-et-Moselle, S. by those of Vosges and Haute-Marne, and W. by those of Marne and Ardennes. About one-half belongs to the basin of the river Meuse, which is enclosed on the west by the wooded region of Argonne, on the east by the hills known as the Côtes de Meuse. On the north-east it is watered by the Orne, a tributary of the Moselle, and the Chiers, which runs by Montmédy to join the Meuse. The other half sends its waters to the Seine by the Aire, a tributary of the Aisne, both of which take their rise here, and by the Ornain, an affluent of the Saulx, the two last being tributary to the Marne. The highest elevation (1388 ft.) occurs to the south-west, on the line of the ridge which separates the basin of the Meuse from that of the Seine. The heights gradually sink from south to north, but seldom fall below 1000 ft. The hills of the Argonne similarly sink rapidly down to the valley of the Saulx, where the lowest level of the department (377 ft.) is reached. Its winters are less severe than those of the Vosges, but it is not so temperate as the Seine region. The average annual rainfall is about 30 in. The chief crops of the department are wheat, oats, rye, barley, clover, potatoes and mangel-wurzels. The vine is cultivated to some extent, the best growths being those of Bar. The forests, occupying more than a quarter of the area, are principally of oak, and are rich in game, as are the rivers in fish. Basket-making is prosecuted in the Argonne. The mineral wealth of the department includes good freestone (Euville, Lérouville). It has iron and steel works, wire-works, and manufactories of files, hardware and edge tools. Ligny-en-Barrois (pop. 4879) manufactures scientific instruments. There are cotton-spinning, wool-weaving, and hemp, flax and jute factories, saw-mills, carriage works, leather manufactures, glassworks, paper-mills, distilleries and flour-mills. The department is served by the Eastern railway, the principal lines being that from Paris to Strassburg through Bar-le-Duc and Commercy, that from Paris to Metz through Verdun, and the branch line of the Meuse valley. The chief waterways are the canal connecting the Marne with the Rhine and the Eastern canal along the Meuse valley; the two together have a length of 145 miles. Ecclesiastically the department forms the diocese of Verdun; it has its court of appeal at Nancy, and constitutes part of the district of the army corps of Châlons-sur-Marne, and of the educational division of Nancy. There are 4 arrondissements—Bar-le-Duc, Commercy, Montmédy and Verdun—28 cantons and 586 communes. The principal places in the department are Bar-le-Duc, the capital, Commercy, Verdun and St Mihiel, which receive separate treatment. Other places of interest are Avioth, which has a church of the 14th and 15th centuries with a beautiful chapel of the 15th century adjoining it, and Rembercourt-aux-Pots with a fine church of the 15th century.

MEUSE-LINE, the chain of French forts closing the passages of the Meuse between Verdun and Toul. The total length of the line is 31 m., and the *forts d'arrêt* are disposed along the right bank. The forts are: between Verdun and St Mihiel, Génicourt and Troyon; near St Mihiel, Les Paroches (left bank) and Camp des Romains; and near Commercy—Liouville St Agnant, Gironville and Jouy-sous-les-Côtes. Above the circle of the Toul defences there are barrier forts on the Upper Meuse at Pagny (la-Blanche-Côte) and near Neufchâteau; but these last are practically in second line, and between Toul and Épinal the frontier districts are designedly left open. At Épinal the "Moselle-Line" begins. These lines form part of the defensive scheme adopted by France in 1873–1875. Their general design is that of the French fort illustrated in FORTIFICATION AND SIEGECRAFT, fig. 43, though they are varied in accordance with the site.

MEVANIA (mod. *Bevagna*), an ancient town of Umbria, on the river Clitumnus and on the Via Flaminia, 8 m. W.S.W. of Forum Flaminii, and 5 m. W. of Fulginium (Foligno), 738 ft. above sea-level. There are remains of a temple near the north gate, and of an amphitheatre built into the modern houses. The walls, which have disappeared, were, according to Pliny (*Hist. Nat.* xxxv. 173), built of unbaked bricks. In 310 B.C. the consul Fabius broke the Umbrian forces here; but otherwise it is not mentioned until the 1st century A.D. In 69 the army of Vitellius awaited here the advance of Vespasian. Its pastures near the river and its white oxen are mentioned by Propertius, whose family belonged to Asisium (mod. Assisi) and after him by Silius Italicus, Lucan and Statius. The town was a *municipium*. The churches of S. Michele Arcangelo and S. Nicolo are Romanesque buildings of the 12th century.

MEW. (1) An imitative word, also spelled *miaou*, representing the cry of a cat or of sea-birds. The name mew, usually sea-mew, as applied to the *Larus canus*, or common sea-gull, is, according to Skeat, also imitative. As the name of the sea-bird it appears in Du. *meeuw*, Ger. *Möwe*, and other languages. (2) (Through Fr. *muer*, from Lat. *mutare*, to change), a term originally applied in French to the moulting of a hawk or falcon, and then to the caging of the bird during that period; thus "to mew up" has come to mean to confine. The English word chiefly survives in the plural form mews, applied to a stable-yard, coach-houses, stalls for horses, and living accommodation, found in narrow streets in large towns. This use was due to the Royal Mews at Charing Cross, where the royal hawks were kept from 1377 to 1537, when the building became the royal stables.

MEWS, PETER (1619–1706), English royalist and divine, was born at Caundle Purse in Dorset on the 25th of March 1619, and was educated at the Merchant Taylors' school, and at St John's College, Oxford, of which he was scholar and fellow. When the Civil War broke out in 1642 he joined the Royalist army, and, having been made a captain, was taken prisoner at Naseby; but he was soon released and in 1648 sought refuge in Holland. He became friendly with Charles I.'s secretary, Sir Edward Nicholas, and being skilful at disguising himself was very useful to the Royalists during the rule of Oliver Cromwell, undertaking two journeys to Scotland in 1653. Before this Mews had been ordained. Taking the degree of D.C.L. and regaining his fellowship at Oxford after the Restoration, he became archdeacon of Huntingdon, vicar of St Mary's, Reading, and chaplain to the king; then, having obtained two other livings, he was made canon of Windsor, canon of St David's, and archdeacon of Berkshire. In 1667, when at Breda arranging peace between England and Holland, he was chosen president of St John's College, Oxford, in succession to his father-in-law, Dr Richard Baylie, afterwards becoming vice-chancellor of the university and dean of Rochester. Appointed bishop of Bath and Wells in 1672, Mews resigned his presidency in 1673, and in 1684 he was elected bishop of Winchester, a position which this "old, honest cavalier," as Thomas Hearne calls him, filled until his death on the 9th of November 1706. The bishop is buried in Winchester cathedral. Mews lent his carriage horses to pull the cannon at a critical moment during the battle of Sedgemoor, where he was wounded whilst accompanying the royal army. He was, however, in sympathy with the seven bishops, and was only prevented by illness from attending their meeting; and as visitor of Magdalen College, Oxford, he supported the fellows in their resistance to James II., admitted their nominee, John Hough, to the presidency, and restored the ejected fellows in October 1688.

He took the oaths to William and Mary in 1689. In the absence of Compton, bishop of London, Mews took the chief part at the consecration of Tillotson as archbishop of Canterbury in 1691.

See S. H. Cassan, *Lives of the Bishops of Winchester* (1827); and the *Nicholas Papers*, edited by G. F. Warner (1886–1897).

MEXBOROUGH, an urban district in the West Riding of Yorkshire, England, on the Don, 11 m. N.E. of Sheffield on the Great Central and Midland railways. Pop. (1891), 7734; (1901), 10,430. The Don affords water communication with the Humber. The church of St John the Baptist has Early English portions. The large industrial population is mainly employed in glass, pottery and iron works, and in the neighbouring stone-quarries. The Castle Hill is crowned with some fine earthworks of uncertain date.

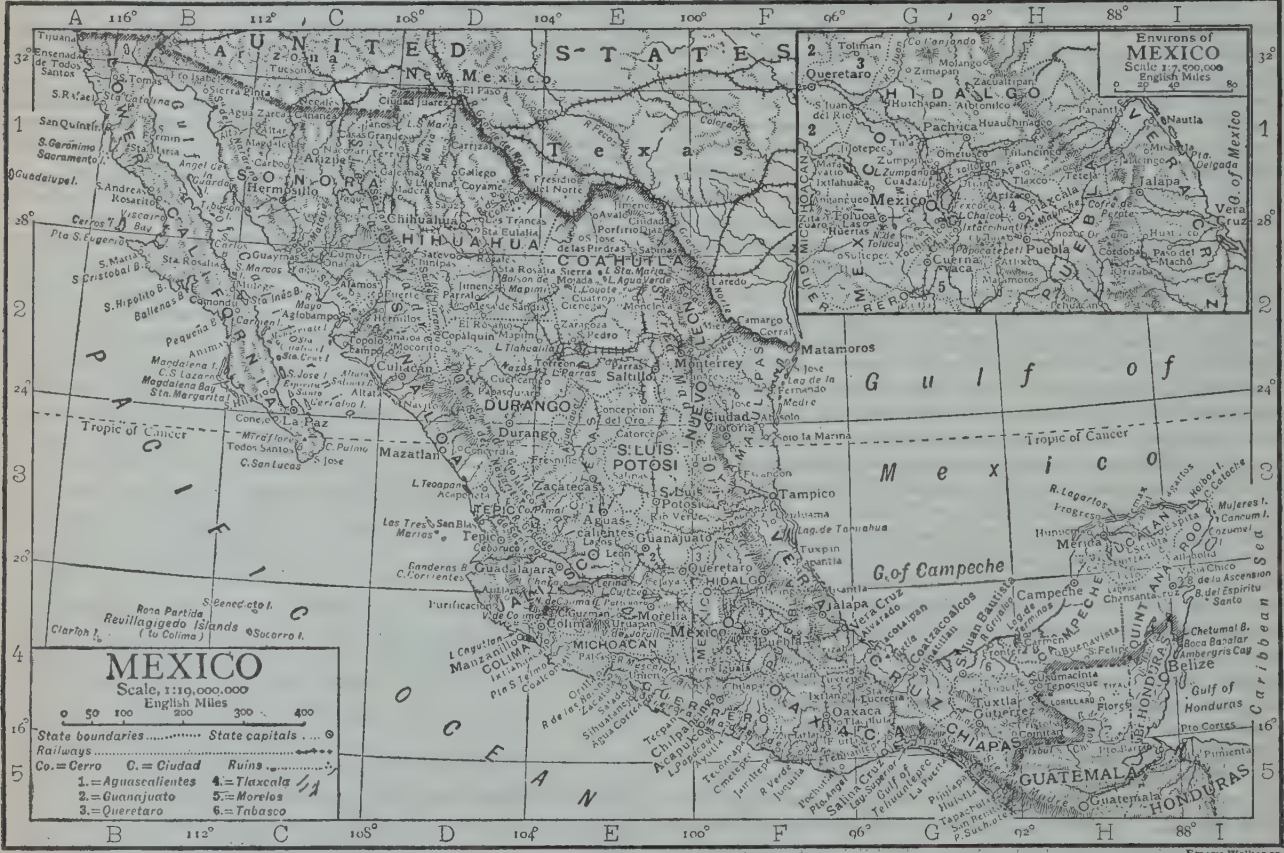
MEXICO (Span. *Méjico*, or *Mexico*,) officially styled *Estados Unidos Mexicanos* and *República Mexicana*, a federal republic of North America extending from the United States of America southward to Guatemala and British Honduras, and lying between the Pacific Ocean on the west and the Gulf of Mexico and Caribbean Sea on the east. Its northern boundary line was fixed by the Guadalupe-Hidalgo treaty of 1848 and the Gadsden treaty of 1853; it follows the Rio Grande del Norte from its mouth north-westward to lat. 31° 47′ N., thence on that parallel W. 100 m., thence S. to lat. 31° 20′ N., thence due W. to the 111th meridian, thence in a straight line (nearly W.N.W.) to a point on the Colorado river 20 m. below the mouth of the Gila river, thence northward to the mouth of the Gila, and thence, nearly due W., along the old line between Upper and Lower California to a point on the Pacific coast one marine league S. of the southernmost point of San Diego Bay; this line has a total length of 1810 m., of which the Rio Grande comprises 1136 and the land route 674 m. The boundary line with Guatemala, for a long time in dispute, was fixed by the treaties of 1882 and 1895. It is an arbitrary line and follows only two natural lines of demarcation—the Suchiate river from the Pacific coast to its source, and the Chixoy and Usumacinta rivers from near the 16th parallel N.W. to a point on the latter 25 kilometres, S. of Tenosique (Tabasco). Between these rivers the boundary line is determined by the peaks of Tacaná, Buenavista and Ixbul, and from the Usumacinta eastward it follows two parallels of latitude, one on the point of departure from that river, and the other, the longer, on that of 17° 49′ to the British Honduras frontier. The boundary with British Honduras was determined by a treaty of 1893 and is formed in great part by the Hondo river down to the head of Chetumal Bay, and thence through that bay to the Boca Bacalar Chica—the channel separating Yucatán from Ambergris Cay. Geographically, Mexico extends from 14° 30′ 42″ (the mouth of the Suchiate) to 32° 42′ N. lat., and from 86° 46′ 08″ to 117° 07′ 31″ W. long. Approximately its greatest length from N.W. to S.E. is 1900 m., its greatest width 750 m., and its least width a little short of 140 m. In outline it is sometimes compared to a huge cornucopia with its small end curving S.E. and N. The interior curve formed by the Gulf of Mexico is comparatively regular and has a coast-line of about 1400 m. The Caribbean coast-line is about 327 m. long, exclusive of indentations. The outer curve facing the Pacific is less regular, is deeply broken by the Gulf of California, and has a coast-line of 4574 m., including that of the Gulf. The peninsula of Lower California (*q.v.*) lies parallel with the mainland coast and extends southward to about 22° 52′N. lat., a distance of nearly 760 m. The area of Mexico is commonly given by English authorities as 767,005 sq. m., by German statisticians as 1,987,201 sq. kiloms. (767,290 sq. m.), and by H. H. Bancroft, who quotes official figures, as 1,962,899 sq. kiloms. (757,907 sq. m.).

Physiography.—The surface features consist of an immense elevated plateau with a chain of mountains on its eastern and western margins, which extends from the United States frontier southward to the Isthmus of Tehuantepec; a fringe of lowlands (*tierras calientes*) between the plateau and coast on either side; a detached, roughly mountainous section in the south-east, which belongs to the Central American Plateau, and a low sandy plain covering the greater part of the Isthmus of Yucatán. The peninsula of Lower California is traversed from north to south by a chain of barren mountains which covers the greater part of its surface. The slopes are precipitous on the east coast, but on the west they break down in hills and terraces to the Pacific. This range may be considered a southward continuation of the Californian Sierra Nevada. The great plateau of Mexico is very largely of volcanic origin. Its superstructure consists of igneous rocks of all descriptions with which the original valleys between its marginal ranges have been filled by volcanic action. The remains of transverse and other ranges are to be seen in the isolated ridges and peaks which rise above the level of the table-land, in some cases forming well-defined basins; otherwise the surface is singularly uniform in character and level. The two noteworthy depressions in its surface, the Valley of Mexico and Bolsón de Mapimí, once contained large bodies of water, of which only small lakes and marshy lagoons now remain. The highest part of this great plateau is to be found in the states of Mexico and Puebla, where the general elevation is about 8000 ft. Southward the slope is broken into small basins and terraces by transverse ranges, and is comparatively abrupt. Northward the slope is gentle, and is broken by several transverse ridges. At Ciudad Juarez (adjoining El Paso, Texas), on the northern frontier, the elevation is 3600 ft., which shows a slope of only 4½ ft. to the mile. Less is definitely known of the elevated regions of Chiapas, on the border of Guatemala, which are separated from the great Mexican Plateau by the low Isthmus of Tehuantepec (718 ft. at the highest point of the transisthmian railway), but their general elevation is much lower, and they are broken by wooded sierras and eroded by water-courses.

The mountain ranges which form part of the great Mexican Plateau consist of two marginal chains known as the Sierra Madre Occidental, on the west, the Sierra Madre Oriental, on the east, and a broken, weakly-defined chain of transverse ranges and ridges between the 18th and 20th parallels known as the Cordillera de Anáhuac. All these chains are known locally under diverse names. The Sierra Madre Occidental consists of several parallel ranges in the north, where a broad belt of country is covered with a labyrinth of ridges and valleys. The most eastern of these are known as the Sierra Tarahumare and Sierra del Durango, and the most western as the Sierra del Nazareno, Sierra Yaqui and Sierra Fuerte. These converge in southern Sinaloa and Durango to form the Sierra de Nayarit. Near the 20th parallel the great chain again divides, the eastern part crossing the southern end of the plateau, and the western, or Sierra Madre del Sur, following the shore line closely to Tehuantepec. The Sierra Madre Occidental has but few noteworthy elevations, its culminating points being the Nevado de Colima (14,363 ft.) and Volcán de Colima (12,750 ft.) in the state of Jalisco. In the Sierra de Nayarit the Cerro Pimal rises to an elevation of 11,319 ft., and in the extreme south the Cerro del Leone to 10,302 ft. These sierras lying near the coast have an imposing appearance from the lowlands, but when seen from the plateau their general elevation is so dwarfed as to render them comparatively inconspicuous. The Sierra Madre Oriental consists of a broken chain of ranges extending along the eastern margin of the plateau from the great bend in the Rio Grande south-eastward to about the 19th parallel. In the north these ranges are low and offer no great impediment to railroad building. South of Tampico, however, they are concentrated in a single lofty range. This range extends south-eastward along the western frontier of Vera Cruz (state) and includes the snow-capped cone of Orizaba or Citlaltepetl (18,209 ft.), and the Cofre de Perote, or Nanchampapetl (13,419 ft.). The eastern slopes are abrupt and difficult, and are a serious impediment to communication with the coast. Rising from the open plateau half way between this range and the city of Mexico is the isolated cone of Malinche, or Malintzin (14,636 ft.). Crossing the highest part of the Mexican Plateau is a broken series of ranges, which form the water-parting between its northern and southern slopes. To a part of these ranges has been given the name of Cordillera de Anáhuac, but there is no true cordillera across this part of Mexico. In a general sense these ranges may be considered part of the eastern branch of the Sierra Madre Occidental, which turns eastward on the 20th parallel and crosses the plateau in a south by east direction. Southward the plateau is traversed by many low ranges and breaks down in terraces, forming one of the most fertile and attractive parts of the republic. Close to the capital are the Sierra de Ajusco, whose highest point is 13,078 ft. above sea-level, the Nevado de Toluca (15,168 ft.), in a range which separates the valleys of Mexico and Toluca, the Montes de las Cruces, and that volcanic, spur-like range, running northward at right angles to the axis of the other ranges, whose culminating points, some 20 m. south-east of the city, are the gigantic, snow-clad volcanoes of Popocatepetl (Smoking Mountain) and Ixtaccihuatl (White Woman). Both of them are extinct and Popocatepetl no longer smokes. Their elevations, according to the Comisión Geográfica Exploradora, are 17,888 and 17,343 ft. respectively, that of Ixtaccihuatl being the highest of its three crests. This part of Mexico is highly volcanic in character, the transverse ridge just described having a large number of extinct volcanoes and at least three (Colima, Jorullo and Ceboruco) that are either active or semi-active. Colima was in a state of eruption as late as 1909, Jorullo (4262 ft.) is said to date from 1759, when its cone was formed, and Ceboruco (7100 ft.) in the territory of Tepic, shows occasional signs of activity. Near the coast in the state of Vera Cruz is San Martin, or Tuxtla (9708 ft.), which has been quiescent since its violent eruption of the 2nd of March 1793. Orizaba is sometimes included among the semi-active volcanoes, but this is a mistake. It has been quiescent since 1566, and is now completely extinct. Earthquakes are common throughout the greater part of the republic, especially on the western coast. They are most violent from San Blas southward to the Guatemala frontier, and some of the Spanish towns on or near this coast have suffered severely. Chilpancingo, in Guerrero, was badly shattered in 1902, and in 1907, and in 1909 was reduced to a mass of ruins. The earthquake shocks of the 30th and 31st of July 1909 were unusually severe throughout southern Mexico, reducing Acapulco and Chilpancingo to ruins and shaking the city of Mexico severely. In Acapulco a tidal wave followed the shock. Slight shocks, or *temblores*, are of almost daily occurrence. According to Humboldt's theory there is a deep rent in the earth's crust about the 19th parallel through which at different periods the underground fires have broken at various points between the Gulf of Mexico and the Revillagigedo Islands. "Only on the supposition that these volcanoes, which are on the surface connected by a skeleton of volcanic rocks, are also united under the surface by a chain of volcanic elements in continual activity, may we account for the earthquakes which in the direction mentioned cause the American continent, from the Gulf of Mexico to the Pacific Ocean, to oscillate at the same time" (*Egloffstein*, p. 37).

The lowland or *tierra caliente* region, which lies between the sierras and coast on both sides of Mexico, consists of a sandy zone of varying width along the shore-line, which is practically a tidewater plain broken by inland channels and lagoons, and a higher belt of land rising to an elevation of about 3000 ft. and formed in great part by the débris of the neighbouring mountain slopes. On the Pacific side there are places where the mountain spurs extend down to the coast, but in general this lowland region ranges from 30 to 40 m. in width, except in southern Vera Cruz, Tabasco, Campeche and Yucatán, where it extends farther into the interior. The talus zone of this region, especially at elevations of 1000 to 3000 ft., is noted for its great fertility and the luxuriance of its vegetation.

There are no large islands on the coast of Mexico, and most of the smaller ones are unimportant. Many of those that fringe the Gulf coast are sand-keys, or parts of a new coast formation. They are commonly barren and uninhabitable. The Isla del Cármen, which partly shuts in the Laguna de Términos (Campeche), is one of the largest of this class, and has the town and port of Cármen at its western extremity. On the northern coast of Yucatán is the small, inhabited island of Holbox or Holboy, and on the eastern coast the islands of Mujeres, Cancum and Cozumel, of which the first and last have a considerable population and good ports. On the Pacific coast there are a number of islands off the rocky shores of Lower California and in the Gulf of California—most of them barren and uninhabitable like the adjacent coast. The largest of these, some of them inhabited, are: Guadalupe—about 75 m. west of the coast on the 29th parallel, which is fertile and stocked with cattle; Cerros, off Viscaino Bay, and Santa Margarita, which partly shelters Magdalena Bay, on the Pacific side; and Angel de la Guarda, Tiburon, San Marcos, Cármen, Monserrate, Santa Catalina, Santa Cruz, San José, Espiritu Santo and Cerralvo in the Gulf. Lying off San Blas in the broad entrance to the Gulf are the Tres Marias, and directly west of Colima, to which it belongs, is the scattered volcanic group of Revillagigedo.



Emery Walker sc.

The peculiar surface formation of Mexico—a high plateau shut in by mountain barriers, and a narrow lowland region between it and the coast—does not permit the development of large river basins. Add to this the light rainfall on the plateau and a lack of forests, and we have conditions which make large rivers impossible. The hydrography of Mexico, therefore, is of the simplest description—a number of small streams flowing from the plateau or mountain slopes eastward to the Gulf of Mexico and westward to the Pacific. Most of these are little more than mountain torrents, but one has a course exceeding 500 m., and few have navigable channels. The principal watershed is formed by the sierras of the state of Mexico, from which streams flow north-east to the Gulf of Mexico, north-west to the Pacific and south-west to the same coast below its great eastward curve. The Rio Grande del Norte, or Rio Bravo, on the northern frontier, is practically an American river, as it rises in American territory and receives very little water from the Mexican side. Its larger Mexican tributaries are the Rio de los Conchos, Salado and Pesqueria. Of the Suchiate and Hondo, which form part of Mexico's southern boundary, the first is a short, impetuous mountain torrent flowing into the Pacific, and the other a sluggish lowland stream rising in north-eastern Guatemala and flowing north-east through a heavily forested region to Chetumal Bay. The peninsula of Yucatán has no rivers, and that of Lower California only a few insignificant streams in the north. This is due to the porosity of the soil in the former, and the very limited rainfall in the latter. The largest rivers of Mexico are: the Rio Grande de Santiago, called the Lerma above Lake Chapala, rising in the state of Mexico and flowing westward across Guanajuato, Jalisco and

Tepic to the Pacific coast, with a total length of 540 m., celebrated for its deep canyons and waterfalls; the Rio de las Balsas, or Mescala, which rises in Tlaxcala and flows south and west to the Pacific with a course of 426 m.; the Yaqui, which rises in western Chihuahua and, after breaking through the northern ranges of the Sierra Madre Occidental, flows south-westerly across Sonora to the Gulf of California, with a length of 390 m.; the Grijalva, also called the Chiapas on its upper course, which has its sources in the state of Chiapas and flows north-west and north across Tabasco to the Gulf of Mexico, with a total length of 350 m.; the Fuerte, which rises in southern Chihuahua and, after breaking through the sierras, flows south-west across Sinaloa to the Gulf of California, with a course of 340 m.; the Usumacinta, which is formed by the confluence of the Chixoy and Pasión on the east frontier of Chiapas, and flows north-west across Tabasco to the Grijalva, with a course of 330 m.; and the Pánuco, which has its source in the north-west of the state of Mexico and flows north-eastward to the Gulf of Mexico. The rivers of the Pacific coast have no navigable channels worth mentioning, but many on the Gulf coast are navigable for considerable distances. The more important of these are in Tabasco—the Grijalva, navigable for about 93 m., and the Usumacinta, for about 270 m. The country about the Laguna de Términos is low and flat, and is traversed in all directions by deep, sluggish streams. Many of the rivers crossing the lowlands bordering the Gulf have short navigable channels, the most important of which is the Pánuco and its tributaries. The Rio Grande is navigable for small vessels up to Matamoros (31 m.), and for smaller craft 65 m. farther. Nearly all the Gulf coast rivers, however, are obstructed by bars owing to the quantity of silt brought down from the sierras and the prevailing winds and currents on the coast.

The lakes of Mexico are small and few in number. They may be divided into two classes; those of the plateau region which occupy lacustrine depressions and receive the drainage of the surrounding country; and the tide-water lagoons of the coast formed by the building up of new sand beaches across the indentations in the coast-line. Of the former, the best known are the lakes of the Valley of Mexico—Texcoco, Chalco, Xochimilco, Zumpango, Xaltocán and San Cristobal—which are probably the remains of a lake once occupying the whole valley. They receive considerable surface drainage, but are slowly diminishing in area. Some of them, like Xochimilco, will eventually disappear. The largest, Texcoco, has an area of about 11½ sq. m. (30 sq. kiloms.), but it covered a much larger area at the time of the Spanish conquest. Its surroundings are bleak and sterile and its waters brackish and polluted with the drainage of the neighbouring city for nearly four centuries. The other lakes are wholly different in character and surroundings, especially Chalco and Xochimilco. Texcoco is now connected with the new drainage works of the capital and is no longer a menace to its population through inundations and pestilential fevers. Another group of lakes is to be found in the Laguna district of south-western Coahuila, where the Tlahualila, Mairan, Parras and others occupy a large lacustrine depression and receive the waters of the Nazas and Aguanaval rivers from the south-west (Durango). The size of this isolated drainage basin is very large, the Nazas River alone having a length of about 370 m. The great Mapimí desert of western Coahuila is another lacustrine depression, but only marshy lagoons remain. In eastern Coahuila, near Monclova, are the Agua Verde and Santa Maria lakes, and in eastern Chihuahua there is a similar group. The largest and most attractive of the plateau lakes is Chapala, in the state of Jalisco, about 80 m. long by 10–35 m. wide, which receives the waters of the Lerma and discharges into the Pacific through the Santiago. On the lower terraces of Michoacán are Patzcuaro and Cuitzéo lakes, and elsewhere among the sierras are numerous other small bodies of water. Among the tide-water lagoons, of which there are many along the Gulf coast, the best known are the Laguna de Términos in Campeche, Tamiahua in Vera Cruz, Madre (130 m. long), Pesquerias (21 m. long) and Chairel (near Tampico) in Tamaulipas. All these lagoons are navigable, and those of northern Vera Cruz and Tamaulipas, when connected and improved, will afford a safe inland route for some hundreds of miles along the coast. The north coast of Yucatán is remarkable for the extensive banks built up by the Gulf current from 5 to 7 m. from the shore-line. Inside the present sandy coast is a peculiar tide-water channel called the Rio Lagartos, which follows almost the whole northern shore, with occasional openings or *bocas*, connecting with the open sea. It is apparently of the same character as the lagoons of Tamaulipas. There are a number of these lagoons on the Pacific coast—such as Superior and Inferior near Salina Cruz, Papacayo, near Acapulco, Cayutlan, near Manzanillo, and Tecapan in Tepic—but they are usually shallow, sometimes swampy, and have no value for commerce.

There is a marked difference between the Gulf and Pacific coast-lines of Mexico in regard to their minor indentations and harbours. The south-west part of the Gulf of Mexico is called the Gulf of Campeche (Campeachy), but no distinction is necessary. This coast has no bays of importance, its rivers are obstructed by sand-bars, and it has only one natural harbour—that of Cármen and the Laguna de Términos, which has sufficient depth for the larger classes of vessels and is sheltered by the islands of Cármen and Puerto Real. Of the principal ports on this coast, Matamoros, Tampico, Tuxpan, Coatzacoalcos and Frontera are on rivers, which are obstructed by bars. Tampico and Coatzacoalcos, however, have been improved by breakwaters or jetties, and the deepening of the Channels across the bars, into safe and commodious harbours. Vera Cruz is an open anchorage inside a series of reefs which afford no protection to vessels from the "northers." A breakwater has remedied this defect and Vera Cruz is no longer considered a dangerous port. Campeche has a small artificial harbour, which is so silted up that vessels drawing 9 ft. must anchor 1 m. outside and larger vessels still farther away. Progreso, Yucatán, has only an open roadstead, and large vessels cannot approach its landing-place nearer than 6 m. On the east coast of Yucatán there are two deep, well-sheltered bays, Ascensión and Espiritu Santo, which afford good anchorages, and at the north end of the island of Cozumel the bay of Santa Maria offers an excellent harbour. The Pacific coast has several deep and well-sheltered bays; but they are separated from the interior by the rough and difficult ranges of the Sierra Madre Occidental. There are two large indentations of the coast—the Gulfs of Tehuantepec and California. The former is opposite the Gulf of Campeche, and possesses no distinguishing characteristic. The Gulf of California, on the other hand, penetrates the continent for a distance of 739 m., from south-east to north-west, with a maximum breadth of 190 m. Its area is usually restricted to the waters north of the latitude of Cape San Lucas, but it should be extended to the outer waters enclosed by a line from Cape San Lucas to Cape Corrientes. Its upper waters are not much navigated because of the aridity of its coasts, but there are two or three important ports towards the south. The Gulf has a considerable number of islands, most of them near the peninsular coast, and several deep, well-protected bays—those of La Paz and Santa Inés in Lower California, Guaymas in Sonora, Agiobampo, Topolobampo and Altata Salinas in Sinaloa. On the Pacific coast of Lower California are the Ensenada de Todos Santos and the bays of San Quentin, Viscaino and Magdalena. The principal bays on the mainland coast are Olas Atlas, which is the harbour of Mazatlán, San Blas, Banderas, Manzanillo, Acapulco, Salina Cruz and Tonalá. Several of these are being improved.

[*Geology*.—By far the greater part of Mexico is covered by deposits of Cretaceous and later date, the pre-Cretaceous rocks occurring only in comparatively small and isolated patches. At the southern extremity of the great table-land, however, in the state of Puebla, there is a considerable mass of crystalline rocks which is believed to be of Archaean age. Similar rocks occur also in Chiapas, Oaxaca, Guerrero and elsewhere; but owing to the absence of any early fossiliferous deposits, the age of these rocks is very uncertain. Silurian and Devonian fossils have been reported at one or two localities, but for the present the observations are open to doubt. The earliest fossiliferous beds which have been proved to exist in Mexico belong to the Carboniferous system. They are found on the borders of Guatemala and consist of limestones and dolomites with Productus.

The Mesozoic beds are of greater importance. The Triassic and Jurassic systems are met with only in scattered patches. The former consists of sandstones and clays, and the fossils found in them are chiefly plants, including *Gangamopteris* and *Macrotaeniopteris*, two characteristic genera of the Indian Gondwana system. The Jurassic beds are marls, sandstones and limestones, which contain marine fossils. The Cretaceous rocks take a far larger share in the formation of the country. They form the greater part of the Sierra Madre Oriental and also cover most of the central plateau. They contain many fossils, including Hippurites and Ammonites. The sedimentary deposits of the Tertiary era do not occupy a very wide area. They occur, however, along the coasts, where they are marine, and also on the central plateau, where they are of lacustrine origin. But by far the most important of the Tertiary rocks are the volcanic lavas, agglomerates and ashes, which cover so much of the country. It is in the western half of Mexico that they are most fully developed, but towards the southern extremity of the plateau they spread nearly to the eastern coast. The eruptions are said to have begun with the ejection of syenites, diorites and diabases, which probably took place at the close of the Cretaceous or the beginning of the Eocene period. In the Miocene period andesites of various kinds were erupted, while at the close of the Pliocene began the great eruptions of basalt which reached their maximum in Quaternary times and continue to the present day.[1] (P. La.)]

Climate.—Mexico stretches across 17 parallels of latitude, with the Tropic of Cancer crossing her territory about midway. This implies tropical and sub-tropical conditions. The relief of the land and varying degrees of rainfall and vegetation, however, serve to modify these conditions in many important particulars. The elevation and extent of the great central plateau, which penetrates deeply into the tropical half of the country, carry with them temperate and sub-tropical conditions over much the greater part of the republic. Above the plateau rise the marginal sierras, while a few isolated peaks in the region of perpetual snow give to Mexico a considerable area of cold temperate and a trace of arctic conditions. Descending to the lowlands on either side of the plateau, the temperature rises steadily until the upper limit of the tropical region, called *tierras calientes*, is reached, where the climate is hot, humid and unhealthy, as elsewhere in the forested coastal plains of tropical America.

---

[1] See J. G. Aguilera, *Sinopsis de geologia mexicana*; "Bosquejo geológico de México," segunda parte, Bol. inst. geol., Mexico, Nos. 4–6 (1897), pp. 189–270, with map—a summary of this paper will be found in *Science Progress*, new series (1897), vol. i. pp. 609–615. See also the *Livret-guide* of the Tenth Cong. Géol. Internat. (1906).

The *tierras calientes* (hot lands) of Mexico include the two coastal zones, the Isthmus of Tehuantepec, the states of Tabasco, Campeche, and part of Chiapas, the peninsula of Yucatán and a part of eastern Oaxaca. The mean temperature ranges from 77° to 82° F., seldom falling below 60°, but often rising to 105°, and in the sultry districts of Vera Cruz, Guaymas and Acapulco to and even above 110°. The rainfall is heavy in the south, except Yucatán, but diminishes gradually toward the north, until on the Pacific and Gulf of California coasts it almost disappears. These lowland districts are densely forested in the south, except Yucatán, and large areas are covered with streams, swamps and lagoons, the abode of noxious insects, pestilential fevers and dysentery. On both coasts yellow fever epidemics appear at frequent intervals. The great fertility of these regions and the marvellous wealth of their forests are irresistible attractions to industrial and commercial enterprise, but their unhealthiness restricts development and is a bar to any satisfactory increase in population. The heavy rainfall on the Gulf coast, however, which reaches a maximum of 90 to 100 in. in the Huatusco district of Vera Cruz, causes the flooding of large areas of lowlands, and will make improvement very difficult. The peninsula of Yucatán, whose general level does not rise above 130 to 200 ft. above the sea, consists almost wholly of an open, dry, calcareous plain. The temperature ranges from 66° to 89°, but the heat is tempered by the cool sea-breezes which sweep unobstructed across its plains. The rainfall is abundant in the rainy season, but in the long dry season it is extremely rare. In the wet season the rain is quickly absorbed by the dry, porous soil; consequently there are no rivers and no lakes except near the forested region of the south-east. These exceptional conditions give to Yucatán a moderately hot, dry, and comparatively healthful climate. Another hot, dry climate is that of the *tierras calientes* of Sonora. The coast is low and extremely arid, and would be uninhabitable were it not for the proximity of the Sierra Madre, where a light rainfall is experienced, and for the numerous rivers that cross the arid belt between the mountains and the sea. The maximum temperatures in this region are 98° at Hermosillo and 119° at Guaymas.

To a large extent the climate of Mexico is determined by vertical zones. According to H. H. Bancroft (*Resources of Mexico*, pp. 3–4), the *tierras calientes*, which include a coastal zone 30 to 40 m. wide and the low-lying states already mentioned, rise from sea-level to an elevation of 3280 ft. The *tierra templada*, or sub-tropical zone, rises to an elevation of 5577 ft., and comprises "the greater portions of Coahuila, Nuevo León, San Luis Potosí, nearly half of Tamaulipas, a small part of Vera Cruz, nearly the whole of Chiapas, nearly all of Oaxaca, a large portion of Guerrero, Jalisco, Sinaloa and Sonora," together with small parts of the inland states of Puebla, Mexico, Morelos and Michoacán. The mean annual temperature is about 75°. Above this is the *tierra fria*, which ranges from 5577 to 8200 ft., and includes all the higher portions of the Mexican plateau, and which corresponds to the temperate regions of Central United States where frosts are very rarely experienced. Even here the high sun temperatures give a sub-tropical character to the country. In the sierras, above the *tierras frias*, which are not "cold lands" at all, are the colder climates of the temperate zone, suitable for cereals, grazing and forest industries, and, farther up, the isolated peaks which rise into the regions of snow and ice.

Speaking generally, the four seasons are clearly marked north of lat. 28° N. only. South of that parallel they merge in the *estación de las aguas*, or rainy season, from May to October, and the *estación seca*, or dry season, which prevails for the rest of the year. The rains generally begin on the east coast and gradually move northwards. The windward slopes of the Sierra Madre Oriental receive the greater part of the rainfall, and the winds, deprived of their moisture, pass over the northern plateau without further precipitation. On the Pacific coast the belt of calms, known as the northern horse latitudes, crosses the northern parts of Lower California and Sonora, which accounts for their extreme aridity. The southern terraces of the plateau have no high mountain barriers between them and the moist winds of the Caribbean, and they too receive an abundant rainfall in the wet season, especially during the prevalence of heavy "northers" on the Gulf coast. The precipitation varies widely, that of the western side of the northern plateau (Chihuahua and Durango) being about 39 in., that of the Valley of Mexico about 25 in., and that of the whole republic 59 in. Long droughts are common in many parts of the country, and on the barren surfaces of the plateau the rains drain away rapidly, leaving but slight beneficial results.

Flora and Fauna.—The types of animal and vegetable life found in Mexico belong, in a general sense, to those of the northern temperate region, and those of the tropical regions of Central and South America. The great central plateau and its bordering lowlands form an intermediate territory in which these dissimilar types are found side by side, the tropical species extending northward along the coast to the United States, while the northern species have found their way to the southern limits of the plateau. The jaguar and puma have found their way into the United States, while the wolf, coyote, bear and beaver have gone far southward on the plateau, and the buffalo was once found in large numbers on its more favoured northern plains. This intermingling of types does not apply to south-eastern Mexico, where animal life is represented by many of the genera and species found in the forested lowlands of the great Amazon basin.

Aside from its origin, the fauna of Mexico includes at least five species of monkey, the jaguar, puma, ocelot (*Felis pardalis*), wolf, coyote, lynx, badger, otter (*Lutra felina*), beaver, muskrat, bear, raccoon (*Procyon*), coati (*Nasua*), tapir, two species of peccary (*Dicotyles torquatus* and *D. labiatus*), skunk (*Mephitis*, *Spilogale* and *Conepatus*), marten, several species of opossum (including a pigmy species of the Tres Marias islands), sloth, two species of ant-bear (*Myrmecophaga tetradactylus* and *Cyclothurus didactylus*), armadillo (*Dasypus novemcinctus*), a small arboreal porcupine (*Synetheres mexicanus*), the kinkajou (*Cercoleptes caudivolvulus*), three species of deer—the white-tailed *Cariacus toltecus*, the little black-faced brocket, *Coassus rufinus*, which is also found in Brazil, and the Sonora deer (*Odocoileus couesi*)—the Mexican bighorn (*Ovis mexicanus*) of Chihuahua, at least two species of hare (*Lepus calotis* and *L. palustris*), rabbits, black, gray, red and ground squirrels, gophers, and many small rodents. Alligators and crocodiles are numerous in the lagoons and rivers of the coast and the iguana is to be found everywhere throughout the tropical lowlands, the large black *Ctenosura acanthinurus* being partly arboreal in habit when full grown. Mexico is a paradise of lizards, which are noted for their diversity in form as well as for their remarkable colouration. Frogs and toads are represented by scores of species, some of which, *e.g.* the tree-frogs (*Hylidae*), are extremely interesting. The ophidians are also very numerous, ranging from the comparatively harmless boa-constrictor to the deadly "palanca" or "fer de lance" (*Lachesis lanceolatus*) and rattlesnake (*Crotalus*), of which there are several species. In southern Mexico in 1902 and 1904 Hans Gadow collected specimens of 44 different kinds of snakes, which he estimated to be only about 45% of the species in the states visited. The arboreal life of the tropical forests has developed the tree-climbing habit among snakes as well as among frogs and toads, and also the habit of mimicry, their colour being in harmony with the foliage or bark of the trees which form their "hunting-grounds." Bats are numerous, both in species and individuals. The sanguinary vampire (*Desmodus rufus*) has an extensive range through the *tierras calientes* and *tierras templadas* of the southern states. The coasts of Mexico, together with their accessible lagoons and rivers, afford innumerable breeding-places for turtles, which include the large green and tortoise-shell species. In some places the capture of the latter is the source of a considerable export trade in tortoise-shell. The coast of Lower California is a favourite resort for the fur-bearing seal, and pearl oysters find a congenial habitat in the south waters of the Gulf. There are some good fishing-grounds on the coasts, but fishing as an organized industry does not exist. The inland waters, with the exception of Lake Chapala, have comparatively few species, but the government has introduced carp, brook-trout and salmon-trout.

The avifauna of Mexico includes most of the species of the tropical and temperate regions of America—such as parrots (chiefly the yellow-headed *Chrysotis*), parakeets (*Conurus canicula*), macaws (*Ara macao* and *A. militaris*), toucans, trogons, herons, egrets, ibis, spoonbills, boat-bills (*Cancroma*), ducks, pelicans, cormorants, bitterns, stilts, sandpipers, curlews, grackles, kingfishers, motmots, "Chachalacas" (*Ortalida poliocephala*), woodpeckers, jays, cuckoos, "garrapateros" (*Crotophaga sulcirostris*), the ingenious weaver-bird (*Icterus*), and another species (*Cassicus*), whose curiously woven, sack-like nests are suspended from the slender limbs of trees, and sometimes even from telegraph-wires, scarlet-crested fly-catchers (*Muscivora mexicana*), tanagers, mocking-birds (called "zenzontl"), turkeys, partridge, quail (*Colinus*, *Lophortyx*, *Callipepla* and *Cyrtonyx*), doves, pigeons, eagles, caracara hawks (*Polyborus*), fish-hawks, falcons, crows, and turkey-buzzards (both the red-faced "aura" of North America and the black-faced "zopilote" of the tropics), which are the scavengers of the country. The most numerous, perhaps, are the humming-birds, of which there are many genera and species, each one distinct in form and colour. They are called "huitzilin" (spikelet) by the Aztecs, and "colibrí," "chupaflor" and "chupa-miel" (flower- or honey-sucker), and "pájaro-mosca" (fly-bird) by the Spanish-speaking Mexicans. These descriptive names are highly poetic, as also that of the Portuguese, "beija-flor" (flower-kisser); but the humming-bird is insectivorous, and thrusts his long bill into flowers in search of insects instead of honey. Mexico is credited with a great variety of song-birds, but these are to be found chiefly in the partly-forested country of the *tierras templadas* and *tierras frias*. Her chief distinction, however, is in birds of varied and gorgeous feathering. The wonderful plumage of the "quetzal" (*Trogon resplendens*) was, it is said, reserved by the Aztec rulers for their own exclusive use. Of the indigenous birds, the turkey has been fully domesticated, and the musk-duck and "chachalaca" are easily reared. Sea-fowl are most numerous on the coasts of Lower California, where certain islands in the arid belt are frequented at night by countless numbers of them. It should be added that many of the migrating birds of North America pass the winter in Mexico.

The insect fauna of Mexico covers a very wide range of genera and species which, like the other forms of animal life, is largely made up of migratory types. No complete study has ever been made of this fauna, but much has been, and is being done by the U.S. Biological Survey and Plant Industry Bureau. To the traveller, the most conspicuous among the Mexican insects, perhaps, are the butterflies, beetles, ants and the myriads of mosquitoes, midges, fleas and chinches. Among the mosquitoes, which are extraordinarily numerous in some of the hot lowland districts, are the species credited with the spread of malarial and yellow fevers. The midges are even more numerous than the mosquitoes. In pleasing contrast to such pests are the butterflies of all sizes and colours, beetles of an inconceivable variety of size, shape and colouration, and ants of widely dissimilar appearance and habits. An interesting species of the last is the leaf-cutting ant (*Eciton*) which lives in large underground colonies and feeds upon a fungus produced by leaf-cuttings stored in subterranean passages to promote fermentation. These ants will strip a tree in a few hours and are very destructive to fruit plantations. Some of the native trees have developed ingenious methods of defence, one of which is that of attracting small colonies of another species to drive away the marauders. Most destructive, also, are the termites or white ants, whose ravages are to be seen in the crumbling woodwork and furniture of all habitations in the hot zones. Some species build their nests in trees—great globular masses sometimes three feet in diameter, supported on the larger branches, and connected with the ground by covered passages on the outside of the tree. These insects are blind and avoid the light. Bees find a highly congenial habitat in Mexico, and some honey is exported. Spiders are also represented by a large number of genera and species, the most dreaded being the venomous "tarantula" and the savage "mygale."

Few countries, if any, can present so great a diversity in plant life as Mexico. This is due not only to its geographical position and its vertical climatic zones, which give it a range from tropical to arctic types, but also to its peculiar combination of humid and arid conditions in which we find an extensive barren table-land interposed between two tropical forested coastal zones. These widely divergent conditions give to Mexico a flora that includes the genera and species characteristic of nearly all the zones of plant life on the western continents—the tropical jungle of the humid coastal plains with its rare cabinet-woods, dye-woods, lianas and palms; the semi-tropical and temperate mountain slopes where oak forests are to be found and wheat supplants cotton and sugar-cane; and above these the region of pine forests and pasture lands. Then, there are the mangrove-fringed coasts and the dripping wooded slopes where rare orchids thrive, and above these, on the inland side of the sierra, a treeless, sun-scorched table-land where only the cactus, yucca, and other coarse vegetation of the desert can thrive without irrigation.

For convenience of description, the flora of Mexico may be divided into four great divisions: that of the comparatively barren plateau and the arid coast regions, the humid *tierras calientes*, the intermediate *tierras templadas* and *tierras frias*, and the higher regions of the sierras. The line of demarcation cannot be very sharply drawn, as the zones everywhere overlap each other and local climatic conditions greatly modify plant types. In general, the aspect of the great central plateau north of the Anáhuac sierras is that of a dusty, treeless plain. There is but little natural vegetation to be seen—ragged yucca trees, many species of agave and cactus, scrubby mesquite bushes, sage bushes and occasional clumps of coarse grasses. The rainy season completely changes the appearance of these plains, new grass appears, and wheat and Indian corn are cultivated. The rains do not last long, however, and sometimes fail altogether. The most common plants of the Mexican plateau are the agaves, yuccas and cacti, each of which is represented by a number of species. The first is chiefly known in the south by the "magueys," from which the national drinks "pulque" and "mescal" are extracted. There is some confusion in the specific names of these agaves; the "pulque"-producing plant is usually described as the *Agave americana*, though *A. atrovirens* and several others are also credited with the product. The mescal-producing magueys have a thinner leaf and are not cultivated, with the exception of the species producing the "tequila" mescal. The chief value of the agaves, however, is in their fibres, of which a great variety is produced. The principal plateau agaves producing fibre are the *A. lechuguilla* and *A. lophantha* and *A. univittata* of the Jaumave Valley, Tamaulipas, which furnish what may be termed the genuine ixtle fibre. The "tapemete" fibre of western Mexico is credited by Mr E. W. Nelson to the *A. vivipara*, which is found chiefly in the warmer and lower elevations of the Pacific slope. There are many other fibre-producing agaves, including some of those from which pulque is derived. The cactus is unquestionably the characteristic plant of Mexico. About one thousand species have been described, a very large percentage of which are to be found on the Mexican plateau.

Explorations by botanists of the United States Department of Agriculture have been made in many localities, in Jalisco, Zacatecas, Michoacán and Tamaulipas, but many years must elapse before the whole ground can be covered. In central and southern Mexico the mountain slopes are forested up to 12,500 to 13,500 ft., juniper bushes continuing up to 14,000 ft. The forests consist of several species of evergreen and deciduous oaks, "oyamel" (*Abies religiosa*), the arbutus or strawberry tree, the long-leaved *Pinus liophylla* and the short-leaved "ocote" or *Pinus montezumae* and the alder, with an undergrowth of elder (*Sambucus mexicana*), broom and shrubby heath. In the Southern Sierra Madre, the "oyamel" and "ocote" pine are the giants of the forest, sometimes rising to a height of 100 ft. Oaks are to be found over a wide area and at lower elevations of the sub-tropical zone as well. They are represented by a number of species, and are called "roble" and "encina" by the natives.

In the intermediate zones between the higher sierras and the *tierras calientes* the flora is very largely composed of species characteristic of the bordering hot and cold regions. Oaks are everywhere common and the "ocote" pine on the Gulf coast is found as far down as 6300 ft. In southern Mexico the pine is found at even lower elevations where the tropical growth has been destroyed by cultivation and fire. The lower slopes of the sierras, especially those of southern Mexico, are well forested and include an immense number of species. The most common families on the eastern slopes, where the precipitation is heavy, are the magnolias, crotons, mimosas, acacias, myrtles, oaks, plane-trees and bamboos. Palms are common, the chestnut abounds in many places, the cacti are almost as numerous as on the open plateau. On the southern slopes of the Ajusco and other sierras considerable forests of the "ahuehuete" or cypress (*Taxodium distichum*) are to be found. The "higuerilla" or castor-oil plant (*Ricinus communis*) is widely distributed throughout the plateau and the open plains of the lower zones. In some localities the characteristic types of the two climatic extremes, the palm and the pine, are to be found growing side by side.

No brief description can adequately portray the marvellous variety and magnificence of the flora of the *tierras calientes*. Its forests are not composed of one or a few dominating species, as in the cold temperate zone, but of countless genera and species closely interwoven together—a confused mass of giant trees, lianas and epiphytes struggling to reach the sunlight. This struggle for existence has completely changed the habits of some plants, turning the palm and the cactus into climbers, and even some normal species into epiphytes. Among the more important and conspicuous trees of these tropical forests are mahogany, rosewood, Spanish cedar (*Cedrela*), cassias, ceibas (*Bombax*), rubber (*Castilloa*), palms of many species including the oil-producing *Attalea* of Manzanillo and *Acrocomia* of Acapulco, guayacan (*Guaiacum*), logwood (*Haematoxylon campechianum*), brazilwood (*H. boreale*) which should not be confounded with the Brazilian *Caesalpinia*, palo blanco (*Lysiloma candida*), the cascalote and divi-divi trees (*Caesalpinia Cacalaco* and *C. coriaria*), the "zapote chico" (*Achras sapota*) from which chicle is extracted, "zapote prieto" (*Diospyros ebenaster*), wild fig, myrtles, bamboos and many of the types already mentioned in connexion with the sub-tropical zone. Of the 114 species of trees and cabinet-woods, 17 of oil-bearing plants, and over 60 of medicinal plants and dyewoods indigenous to Mexico, by far the larger part are represented in the *tierras calientes*. Among the well-known forest products of this zone are arnotto, jalap, ipecacuanha, sarsaparilla, rubber, orchids and a great variety of gums.

Of the economic plants and products of Mexico, the list is surprisingly long and interesting. The cereals, fruits and vegetables of Europe have been introduced and some of them have done well. Wheat is widely cultivated and a considerable part of the population depend upon it for their bread. Indian corn, which is believed to have had its origin in Mexico, also provides food for a large part of the population. "Tunas" or cactus fruit, red peppers, "zapotes" (the fruit of various trees), "arrayan" (*Myrtus arayan*), "ciruelas" or Mexican plums (*Spondias*), guavas, "huamuchil" (*Pithecolobium dulce*), tamarinds, aguacates (*Persea gratissima*), bananas, plantains, pineapples, grapes, oranges, lemons, limes, granadillas, chirimoyas, mammees (*Mammea americana*), coco-nuts, cacao, mangoes, olives, gourds and melons, are among the fruits of the country, and rice, wheat, Indian corn, beans, yams, sweet potatoes, onions and "tomatoes" (*Physalis*) are among its better-known food products. The food of the common people is chiefly made up of Indian corn, beans, red peppers and "tomatoes." There are about 50 known species of beans (*Phaseolus*) in Mexico and Central America, and probably a dozen species of red peppers (*Capsicum*) which are used both in seasoning and in making chili sauce. The "tomato" or "tomatillo" mentioned, is the fruit of the *Physalis ixocarpa*, sometimes called the "strawberry tomato" and the "Mexican ground-cherry," which is used with red peppers to make chili sauce. The common potato (*Solanum tuberosum*), of which wild varieties are found, is not commonly used as a vegetable, but as a flavouring for soups and other dishes. Among other economic plants are the fibre-producing agaves, the best known of which is the *A. rigida* var. *elongata* which produces the "henequen" fibre, or sisal hemp, of Yucatán, silk or tree-cotton (*Ceiba casearia*), sugar-cane, cotton (*Gossypium*), indigo and "canaigre" (*Rumex hymenosepalus*) whose root contains a large percentage of tannin.

Mexico has suffered much from the reckless destruction of her forests, not only for industrial purposes but through the careless burning of grassy areas. The denuded mountain slopes and plateaus of southern Mexico are due to the prehistoric inhabitants who cleared away the tropical forest for their Indian corn fields, and then left them to the erosive action of the tropical rains and subsequent occupation by coarse grasses. Fire was generally used in clearing these lands, with the result that their arboreal vegetation was ultimately killed and their fertility destroyed. In the valleys of some of these denuded slopes oak and pine are succeeding the tropical species where fires have given them a chance to get a good foothold.

Population.—According to the census of 1900 the population of Mexico numbered 13,607,259, of which less than one-fifth (19%) were classed as whites, 38% as Indians, and 43% as mixed bloods. There were 57,507 foreign residents, including a few Chinese and Filipinos. Since then the Japanese have acquired an industrial footing in Mexico. Under the constitution of 1824 all race distinctions are abolished, and these diverse ethnic elements are nominally free and equal. For many years, however, the Indians remained in subjection and took no part in the political activities of their native country. Since about 1866, spurred on by the consciousness that one of their own race, Benito Juárez, had risen to the highest positions in the gift of the country, they have taken greater interest in public affairs and are already making their influence felt. In southern Mexico the Zapotecas furnish schoolmasters for the village schools. Peonage, however, is still prevalent on many of the larger estates, and serious cruelties are sometimes reported. The government itself must be held partly responsible, as for the transportation of the mountain-bred Yaquis to the low, tropical plains of Yucatán (see Herman Whitaker's *The Planter*, 1909), but the influence of three and a half centuries of slavery and peonage cannot be shaken off in a generation.

According to Humboldt, the census of 1810 gave a total population of 6,122,354, of which the whites had 18%, the mestizos 22% and the Indians 60%. The census of 1895 increased the whites to 22%, which was apparently an error, the mixed bloods to 47%, and reduced the Indians to 31%. It is probable that the returns have never been accurate in regard to the mixed bloods and Indians, but it is the general conclusion that the Indians have been decreasing in number, while the mixed bloods have been increasing. Neglect of their children, unsanitary habits and surroundings, tribal intermarriage and peonage are the principal causes of the decreasing Indian population. Recent observers, however, deny the assertion that the Indians are now decreasing in number except where local conditions are exceptionally unfavourable. The death rate among their children is estimated at an average of not less than 50%, which in families of five and six children, on an average, permits only a very small natural increase. The larger part of the population is to be found in the southern half of the republic, owing to the arid conditions prevailing in the north. The unhealthfulness of the coastal plains prevents their being thickly populated, although Vera Cruz and some other states return a large population. The most favourable regions are those of the *tierras templadas*, especially on the southern slopes of the great central plateau which were thickly populated in prehistoric times.

The dissimilar races that compose the population of Mexico have not been sufficiently fused to give a representative type, which, it may be assumed, will ultimately be that of the *mestizos*. Mexico was conquered by a small body of Spanish adventurers, whose success in despoiling the natives attracted thither a large number of their own people. The discovery of rich deposits of gold and silver, together with the coveted commercial products of the country, created an urgent demand for labourers and led to the enslavement of the natives. To protect these adventurers and to secure for itself the largest possible share in these new sources of wealth, the Spanish crown forbade the admission of foreigners into these colonies, and then harassed them with commercial and industrial restrictions, burdened them with taxes, strangled them with monopolies and even refused to permit the free emigration thither of Spaniards. Out of such adverse conditions has developed the present population of Mexico. It was not till after the middle of the 19th century that a long and desperate resistance to foreign intervention under the leadership of Benito Juárez infused new life into the masses and initiated the creation of a new nationality. Then came the long, firm rule of Porfirio Diaz, who first broke up the organizations of bandits that infested the country, and then sought to raise Mexico from the state of discredit and disorganization into which it had fallen. Suspicion and jealousy of the foreigner is disappearing, and habits of industry are displacing the indolence and lawlessness that were once universally prevalent.

The white race is of Spanish descent and has the characteristics common to other Spanish-American creoles. Their political record previous to the presidency of Porfirio Diaz was one of incessant revolutionary strife, in which the idle, unsettled half-breeds took no unwilling part. The Indian element in the population is made up of several distinct races—the Aztec or Mexican, Misteca-Zapoteca, Maya or Yucateco, Otomi or Othomi, and in smaller number the Totonac, Tarasco, Apache, Matlanzingo, Chontal, Mixe, Zoque, Guaicuro, Opata-Pima, Tapijulapa, Seri and Huavi. As the tendency among separated tribes of the same race is to develop dialects and as habitat and customs tend still further to differentiate them, it may be that some of these smaller families are branches of the others. In 1864 Don Manuel Orozco y Berra found no fewer than 51 distinct languages and 69 dialects among the Indian inhabitants of Mexico, to which he added 62 extinct idioms—making a total of 182 idioms, each representing a distinct tribe. Thirty-five of these languages, with 69 dialects, he succeeded in classifying under 11 linguistic families. A later investigator, Don Francisco Belmar (*Lenguas indigenas de Mexico*, Mexico, 1905), has been able to reduce these numerous idioms to a very few groups. None of them were written except through the use of ideographs, in the making of which the Aztecs used colours with much skill, while the Mayas used an abbreviated form, or symbols.

The Aztecs, who called themselves Mejica or Mexicans after they had established themselves on the high table-land of Mexico, belong to a very large family or group of tribes speaking a common idiom called Nahua or Nahóa. These Nahua-speaking tribes were called the Nahuatlaca, and compose a little more than one-fourth of the present Indian population. They inhabit the western Sierra Madre region from Sinaloa southward to Chiapas, the higher plateau states, which region was the centre of their empire when Cortés conquered them, and parts of Vera Cruz, Tabasco, Oaxaca, Morelos, Aguascalientes and San Luis Potosí. They were energetic and warlike and evidently had not reached the zenith of their power when Cortés came. They had been preceded on the same plateau by the Chichimecs, possibly of the same race, who were conquered by the Aztecs sometime in the 15th century after a supposed occupation of the territory about 400 years. The characteristic civilization of prehistoric Mexico, however, antedates both of these periods.

An Aboriginal race called the Toltecs is said to have occupied Vera Cruz and Tabasco and to have extended its empire westward on the plateau to and perhaps beyond the present capital. They were the builders of the pyramids of Cholula and Teotihuacan, near the city of Mexico, and of Papantla, Huatusco and Tuzapan, in Vera Cruz. One of their towns was Tollan (now Tula) 50 m. north of the national capital, and it is not improbable that the people of Cholula, Texcoco and Tlaxcala at the time of the Spanish invasion were occupying the sites of older Toltec towns. There has been much discussion in regard to the origin of the Toltecs, some assuming that they were a distinct race, and others that they belonged to the Nahuatlaca. Another and perhaps a better supposition is that they belonged to the Maya group, and represented a much earlier civilization than that of the builders of Palenque, Quirigua and Copan. Confirmatory evidence of this is to be found, not only in the character of their constructions, but in the circumstance that a tribe closely akin to the Mayas (the Huastecos) still occupies a retired mountain valley of Vera Cruz, entirely separated from their kinsmen of the south, and that a dialect of the Maya language is still spoken in northern Vera Cruz. There is evidence to show that the Aztecs adopted the civilization of the Toltecs, including their religion (Quetzalcoatl being a god of the Toltecs and Mayas), calendar and architecture. Perhaps the most remarkable of the Mexican races are the Mayas, or Maya-Quiché group, which inhabit the Yucatán peninsula, Campeche and parts of Tabasco, Chiapas, and the neighbouring states of Central America (*q.v.*). The remarkable ruins of Palenque, Uxmal, Chichenitza, Lorillard, Ixinché, Tikal, Copan and Quirigua, with their carved stonework and astonishing architectural conceptions, show that they had attained a high degree of civilization. They were agriculturists, lived in large, well-built towns, cultivated the mountain sides by means of terraces, and had developed what must have been an efficient form of government.

The Mistecas, or Mixtecas, and Zapotecas, who occupy the southern slopes of the central plateau, especially Puebla, Morelos, Oaxaca and Guerrero, form another distinct race, whose traditional history goes back to the period when the structures now known as Mitla, Monte Alban, Xochicalco and Zaachila were built. Their prehistoric civilization appears to have been not inferior to that of the Mayas. They were an energetic people, were never subdued by the Aztecs, and are now recovering from their long subjection to Spanish enslavement more rapidly than any other indigenous race. The Otomis comprise a large number of tribes occupying the plateau north of the Anáhuac sierras. They are a hardy people, and are the least civilized of the four principal native races.

The Totonacs inhabit northern Vera Cruz and speak a language related to that of the Mayas; the Tarascos form a small group living in Michoacán; the Matlanzingos, or Matlaltzincas, live near the Tarascos, the savage Apaches, a nomadic group of tribes ranging from Durango northward into the United States; the Opata-Pima group, inhabiting the western plateau region from Sonora and Chihuahua south to Guadalajara, is sometimes classed as a branch of the Nahuatlaca; the Seris, a very small family of savages, occupy Tiburon Island and the adjacent mainland of Sonora; and the Guaicuros, or Yumas, are to be found in the northern part of the peninsula of Lower California. In southern Mexico, the Chontales, Tapijulapas, Mixes and Zoques inhabit small districts among and near the Zapotecas, the first being considered by Belmar a branch of that family. The Huavis inhabit four small villages among the lagoons on the southern shore of Tehuantepec and have been classed by Belmar as belonging to the Maya stock. The census of 1895 gave these Indian races an aggregate population of nearly 4,000,000, of which nearly 3,450,000 belonged to the first four groups. Three of these four had made important progress toward civilization. Some of the others had likewise made notable progress, among which were the Tarascos, Totonacs and Zoques.

The builders of Casas Grandes (*q.v.*), in Chihuahua, evidently belonged to the Pueblo tribes of Arizona and New Mexico. As for the builders of Quemada, in Zacatecas, nothing positive is known. The ruins apparently are of an earlier period than those of Mitla and Xochicalco, and have no inscriptions and architectural decorations, but the use of dressed stone in the walls, rather than adobe, warrants the conclusion that they belonged to the civilization of southern Mexico.

From the records made at the time of the Spanish conquest, and from the antiquities found in the abandoned cities of prehistoric Mexico, it is certain that the Indians lived in substantial houses, sometimes using dressed stone, inscriptions and ornamental carvings on the more pretentious edifices; they cultivated the soil, rudely perhaps, and produced enough to make it possible to live in large towns; they made woven fabrics for dress and hangings, using colours in their manufacture; they were skilful in making and ornamenting pottery, in making gold and silver ornaments, and in featherwork; they used the fibres that Nature lavishly provided in weaving baskets, hangings, mats, screens and various household utensils. Copper was known to them, and it is possible that they knew how to make cutting instruments from it, but they generally used stone axes, hammers and picks, and their most dangerous weapon was a war-club into which chips of volcanic glass were set. Many of these primitive arts are still to be found in the more secluded districts, and perhaps the best work in pottery moulding in Mexico to-day is that of uneducated Indian artists.

Of the half-breed element which has become so important a part of the Mexican population, no safe estimate can be made. Education, industrial occupation, commercial training and political responsibility are apparently working a transformation in a class that was once known chiefly for indolence and criminal instincts, and many of the leaders of modern Mexico have sprung from this race. Settled government, settled habits, remunerative employment and opportunities for the improvement of their condition are developing in them the virtues of the two parent races. Brigandage was formerly so common that travel without an armed escort was extremely dangerous; under President Diaz, however, not only has such lawlessness been repressed but the brigands themselves have been given regular employment as rural guards under the government. This class is also furnishing the small traders of the towns, overseers on the plantations and public works, petty officials, and to some extent the teachers and professional men of the provincial towns.

Political Divisions.—The republic of Mexico is politically divided into 27 states, one federal district, and three territories. The states are generally subdivided into *distritos* (districts) or *partidos,* and these into *municipios* (municipalities) which correspond to the townships of the American system. The state of Nuevo Léon, however, is divided into *municipios* only, while some other states use entirely different titles for the divisions, the larger being described as *departamentos, cantons* and *municipios*, and the smaller as *partidos, directorias* and *vecindarios rurales.* The Federal District consists of thirteen municipalities. The territory of Lower California is divided into two large districts, northern and southern, and the latter into partidos and municipios—the larger divisions practically forming two distinct territories.

The states and territories, with their areas, capitals and populations, are as follows:—

Name.	Area, sq. m.	Pop. 1900.	Capital.	Pop. 1900.
Aguascalientes	2,950	102,416	Aguascalientes	35,052
Campeche	18,087	86,542	Campeche	17,109
Chiapas	27,222	360,799	Tuxtla Gutierrez	9,395
Chihuahua	87,802	327,784	Chihuahua	30,405
Coahuila	63,569	296,938	Saltillo	23,996
Colima	2,272	65,115	Colima	20,698
Durango	38,009	370,294	Durango	31,092
Guanajuato	11,370	1,061,724	Guanajuato	41,486
Guerrero	24,996	479,205	Chilpancingo	7,497
Hidalgo	8,917	605,051	Pachuca	37,487
Jalisco	31,846	1,153,891	Guadalajara	101,208
Mexico	9,247	934,463	Toluca	25,940
Michoacán	22,874	935,808	Morelia	37,278
Morelos	2,773	160,115	Cuernavaca	9,584
Nuevo León	23,592	327,937	Monterrey	62,266
Oaxaca	35,382	948,633	Oaxaca	35,049
Puebla	12,204	1,021,133	Puebla	93,152
Querétaro	3,556	232,389	Querétaro	33,152
San Luis Potosí	25,316	575,432	San Luis Potosí	61,019
Sinaloa	33,671	296,701	Culiacán	10,380
Sonora	76,900	221,682	Hermosillo	10,613
Tabasco	10,072	159,834	San Juan Bautista	10,543

The area and population of Yucatán include those of the territory of Quintana Roo, which formed part of that state at the time of the census.

Baja, or Lower California, is divided into two districts for administrative convenience. The Distrito del Norte is credited with a population of 7583 and has its capital at Ensenada (pop. 1026); the Distrito del Sur has a population of 40,041 and has its capital at La Paz.

Tepic was detached from the north-west part of Jalisco and organized as a territory in 1889.

Quintana Roo was detached from the state of Yucatán in 1902 and received a territorial government.

The principal cities of Mexico, other than the capitals above mentioned, are as follows, the populations being those of 1900 except when otherwise stated: Acapulco (pop. 4932), a famous port on the Pacific coast in Guerrero, which was wrecked by the earthquake of 1909; Carmen, or Laguna de Términos (about 6000), a thriving commercial town and port on the Gulf coast in Campeche; Celaya (25,565), a railway centre and manufacturing town of Guanajuato; Ciudad Guzman, or Zapotlán (about 17,500), an interesting old town of Jalisco; Cholula (about 9000), an ancient native town of Puebla, widely known for its great pyramid; Comitán (9316), the commercial centre of Chiapas; Cordoba (7974 in 1895), a picturesque Spanish town in the sierras of Vera Cruz; Cuautla (6269), the centre of a rich sugar-producing district of Morelos; Guaymas (8648), a flourishing port of Sonora on the Gulf of California; León (62,623), the largest city in Guanajuato and distinguished for its commercial activity, manufactures and wealth; Linares (20,690), the second city of Nuevo León in size and importance; Matamoros (8347), a prominent commercial centre and river port of Tamaulipas; Mazatlán (17,852), the foremost Mexican port on the Pacific coast; Orizaba (32,894), a city of Vera Cruz famous for its delightful climate and picturesque surroundings; Parral (14,748), a well-known mining centre of southern Chihuahua; San Cristobal (about 16,000), once capital of Chiapas and rich in historical associations; Tampico (16,313), a Gulf port and railway terminus of Tamaulipas; Tehuantepec (10,386), the largest town on the Tehuantepec railway in Oaxaca; Vera Cruz (29,164), the oldest and best known Gulf port of Mexico.

Communications.—Railways began in Mexico with a line of four kilometres between the capital and Guadalupe, which was finished in 1854 and afterwards became a part of the Ferrocarril Mexicano. The latter dates from 1857, when a concession was granted for the construction of a railway from the city of Mexico to Vera Cruz. The French invasion of 1862 found only 10 m. in operation outside of Vera Cruz and military needs led to its immediate extension to Paso del Macho, at the foot of the sierras, about 35 m. At the same time the English company holding the concession extended the Guadalupe line to Puebla. Nothing more was accomplished until after the downfall of Maximilian, and with a liberal subsidy from the Mexican government the Ferrocarril Mexicano was pushed to its completion in 1873. It is celebrated because of the difficulties overcome on the precipitous eastern slopes of the Sierra Madre, the beauties of the mountain scenery through which it passes, and the rapid transition from the hot, humid coastal plain to the cool, arid plateau, 7924 ft. above the sea at Boca del Monte. The railway extends 263 m. between Vera Cruz and Mexico City, to which 58 m. were added in branches from Apizaco to Puebla, and from Ometusco to Pachuca. The line was capitalized at $46,000,000 and has paid a good profit on the investment. The period of active railway construction, however, did not begin until 1878, during the first term of President Porfirio Diaz. In 1874 a concession was granted for a line from the port of Progreso to Mérida (22½ m.), and in 1878 four concessions were added under which 806 m. were constructed. The principal of these four concessions was the Ferrocarril Interoceánico running from Vera Cruz to Mexico City and across the republic toward Acapulco. In 1880 concessions were granted to the F.C. Occidental, F.C. Central Mexicano, F.C. Nacional Mexicano and three others of less importance, aggregating nearly 3500 m. The first three of these have become important factors in the development of Mexico. The first runs southward from the capital to Oaxaca through the rich sub-tropical states of Puebla and Oaxaca, and the other two run northward from the same point to the American frontier. These two lines, popularly called the Mexican Central and Mexican National, have their northern termini at Ciudad Juárez and Laredo on the Rio Grande and connect with American trunk lines at El Paso and Laredo. These two great lines were merged in 1908, with an aggregate capital of $460,000,000 Mexican money, of which the Mexican government holds $230,004,580, or a controlling interest. Important branches of these lines extend to Tampico on the Gulf coast, to Manzanillo on the Pacific coast, and westward and southward into Michoacán and Guerrero, with a coast terminus at or near Acapulco. The next important line is the F.C. Internacional Mexicano, running from Ciudad Porfirio Diaz, on the Rio Grande, south-westward across the plateau to Durango, and is to be extended to Mazatlán, on the Pacific coast. This line was built with American capital and without a subsidy. Another line built with American capital and in connexion with American railway interests extends southward from Nogales, on the northern frontier, to Hermosillo, Guaymas and Mazatlán; it is to be extended to Guadalajara and possibly to other points in southern Mexico. Monterrey is connected with Tampico by a Belgian line known as the F.C. de Monterrey al Golfo Mexicano, and the capital is to have direct connexion with the Pacific, other than the F.C. Interoceánico, by a line through Cuernavaca and Iguala to the coast. Indirectly the capital has a Pacific coast connexion by way of Cordoba and the F.C. Vera Cruz al Pacifico to a junction with the Tehuantepec line. One of the most important railways in Mexico is the F.C. Nacional Interoceánico de Tehuantepec, also called the Tehuantepec National, and the Mexican Isthmus railway, which is 192 m. long and was formally opened in 1907. This line crosses the Isthmus of Tehuantepec from Coatzacoalcos (officially Puerto Mexico) on the Gulf coast to Salina Cruz on the Pacific coast, and has been under construction many years. The railway was first completed in 1894, but light and defective construction, together with lack of shipping facilities at its terminal points, rendered it useless. To correct these defects the line was completely rebuilt and terminal ports constructed. In 1909 the ports were ready to receive large ocean steamships, and regular traffic was begun, including cargoes of Hawaiian sugar for New York. The highest point on the line (Chivela Pass) is 735 ft. above sea-level. The railway has been built by the Mexican government as a transcontinental route for international commerce. Its final construction together with that of its two ports were executed by S. Pearson & Sons, Ltd., of London, who also undertook the working of the line when open. It was estimated in 1907 that the total cost of the railway and ports when completed would be about £13,000,000. The line is connected at the station of Santa Lucrecia (109 m. from Salina Cruz) with the Vera Cruz and Pacific railway which gives an all-rail connexion with Vera Cruz and Mexico City, the distance between the latter and Salina Cruz being 520 m. According to the President's Message of April 1909, there were 14,857 m. of railway in operation, of which 11,851 m. belonged to or were controlled by the government. It is the evident policy of the Mexican government to prevent the absorption of its railways by private monopolies, and this is effected by state ownership of a controlling share in most of the trunk lines.

Mexico is well provided with tramway lines in its larger cities. A British consular report for 1904 stated that Mexico City and Torreon only were using electric traction, but that Guadalajara, Monterrey, Aguascalientes, Lagos, Colima, Vera Cruz and San Luis Potosí would soon be using it. No official reports are available. The telegraph lines had an aggregate length of 35,980 m. at the end of 1907, of which 33,000 m. belonged to the national government. The President reports an addition of 1626 m. in 1908. Wireless telegraphy was represented in 1908 by a connexion between Mazatlán and Lower California, which was in successful operation. Telephone lines were in use in all the large cities and in connexion with the large industrial enterprises and estates, beside which the government had 500 m. of its own in 1908.

Commerce.—In 1905 the mercantile marine of Mexico comprised only 32 steamers, of 13,199 tons, and 29 sailing vessels, of 8451 tons. The ocean-carrying trade was almost wholly in the hands of foreigners, the government wisely refraining from an attempt to develop an occupation for which its citizens had no natural aptitude. The coastwise trade is principally under the Mexican flag, but the steamers are owned abroad. An official publication entitled "Mexico: Yesterday and To-day, 1876–1904," states that while the number of steamers engaged in the foreign trade increased from 841 to 969 in the 17 years from 1886 to 1903, the number of Mexican steamers decreased from 55 to 4. For the year 1906–1907 the entries of vessels from foreign ports numbered 1697, of 3,282,125 tons, and the clearances were 1669, of 3,257,932 tons. Subventions are paid for regular steamship service at the principal ports, the total expenditure in 1907–1908 being £42,876. These ports are well served by a large number of foreign steamship companies, which give direct communication with the principal ports of the United States, Europe, and the west coast of South America, and the initiation of a Japanese line in 1908 also brings Mexico into direct communication with the far East. The larger ports for foreign trade are Vera Cruz, Tampico, Progreso, Carmen and Coatzacoalcos on the Gulf coast, and Guaymas, La Paz, Mazatlán, Manzanillo, San Blas, Acapulco and Salina Cruz on the Pacific coast. Some of these—Vera Cruz, Tampico, Coatzacoalcos, Salina Cruz, Manzanillo and Mazatlán—have been greatly improved with costly port works. Among the smaller ports, some of which are open to foreign trade, are Matamoros, Tuxpan, Alvarado, Tlacotálpan, Frontera, Campeche and the island of Mujeres (coast of Yucatán) on the Gulf side, and Ensenada, Altata, Santa Rosalia and Soconusco on the Pacific.

The foreign trade has shown a steady increase during the period of industrial development, to which better means of transport have been an invaluable aid. In 1906–1907 the imports were valued at $111,234,968 U.S. gold, and the exports at $123,512,969, of which very nearly one half consisted of precious metals. According to an official report issued early in 1909 there had been a heavy decrease in both imports and exports, the former being returned at $36,195,469 and the latter at $54,300,896 for the six months ending the 31st of December 1908. Too rapid development and overtrading were given as reasons for this decline. Import and export duties are levied, the former in many cases for the protection of national industries. The imports largely consist of railway material, industrial machinery, cotton, woollen and linen textiles and yarns for national factories, hardware, furniture, building material, mining supplies, drugs and chemicals, wines and spirits, wheat, Indian corn, paper and military supplies and equipment. The exports include gold, silver, copper, coffee, henequén or sisal, ixtle and other fibres, cabinet woods, chicle, rubber and other forest products, hides and skins, chickpeas, tobacco and sugar.

Agriculture.—The agricultural resources of Mexico are large and unusually varied, as they comprise some of the cereals and other food products of the temperate zone, and most of the leading products of the tropics. Agriculture, however, received slight attention, owing to the early development of the mining industries. An indirect result of the industrial development of Mexico, which began during the last quarter of the 19th century, has been an increased interest in agriculture, and especially in undertakings requiring large investments of capital, such as coffee, sugar and rubber plantations. A large part of the country is too arid for agriculture, and even with irrigation the water supply is sufficient for only a small part of the dry area. This region has, for the most part, a temperate climate, and produces wheat, barley, Indian corn and forage crops. Long droughts often destroy the wheat and Indian corn and compel their importation in large quantities to supply the people with food. This uncertainty in the wheat crop extends to the southern limits of the higher plateau, and is a serious obstacle to the increased production of this cereal. Indian corn, also, is a comparatively uncertain product on the plateau, and for the same reason. As it is a staple food with the poorer classes, the deficiency is made up through importation. These drawbacks tend to restrict agriculture on the plateau to comparatively limited areas, and the country people are, in general, extremely poor and badly nourished. A comparatively new product in this region is that of canaigre, which is grown for the tannin found in its root. It is a native of the arid regions and is now cultivated with success. The district about Parras, in southern Coahuila, produces grapes, which are principally used in the manufacture of wine and brandy. An important product of the plateau and of the open districts of the *tierras calientes*, growing in the most arid places, is the " nopal " or prickly pear cactus (*Opuntia ficus indica*). Its fruit, called " tuna " by the natives, is refreshing and wholesome and is a staple food in spite of its spiny covering. In the *tierras calientes* of Mexico, however, better conditions prevail. A fertile soil, abundant rainfall and high temperatures have covered these mountain slopes and lowland plains with a wealth of vegetation. The problem for the agriculturist here is not irrigation, but drainage and keeping down spontaneous growths. In these regions, sugar, tobacco, indigo, cacao, rice, sweet potatoes, alfalfa, beans and cassava are produced, and Indian corn yields two and three crops a year. Fruits also are plentiful, both wild and cultivated. Among them are the banana, plantain, tuna, chili pepper, olive, coco-nut, orange, lemon, lime, mango, pomegranate, " piña " or pineapple (wild and cultivated), fig, ahuacatl (*Persea gratissima*), chirimoya (*Anona chirimolia*), papaya, gourd, melon, guava, ciruela (plum), and the several " zapote " fruits, including " chico zapote " from the *Achras sapota*, which produces the " chicla " or chicle-gum of commerce, " zapote blanco " from the *Casimiroa edulis*, " zapote-barracho " (or " amarillo ") from the *Lucuma salicifolia*, " zapote-prieto " (or " negro ") from the *Diospyros obtusifolia*, and " zapote-mamey." The production of rubber is becoming an important industry, large plantations having been set with both *Hevea* and *Castilloa* rubber trees. Lying between these two regions is the subtropical belt where coffee of an excellent quality is produced, and where cotton is cultivated. Coffee has become an important article of export, but cotton does not yield enough for the domestic factories. Better cultivation would probably increase the output and make it an article of export. A peculiar and highly profitable branch of Mexican agriculture is the cultivation of the *Agave* for two widely different purposes—one for its fibre, which is exported, and the other for its sap, which is manufactured into intoxicating liquors called " pulque " and " mescal." In Yucatán immense plantations of the *Agave rigida* var. *elongata* are cultivated, from which large quantities of " henequén " or " sisal," as the fibre is called, are exported. It is produced on light shallow soils overlying calcareous rock. It is also cultivated in Campeche and Chiapas. The pulque industry is located on the plateau surrounding the city of Mexico, the most productive district being the high, sandy, arid plain of Apam, in the state of Hidalgo, where the " maguey " (*Agave americana*) finds favourable conditions for its growth—a dry calcareous surface with moisture sufficiently near to be reached by its roots. Its cultivation is the chief industry of the states of Mexico, Hidalgo, Puebla and Tlaxcala. Of the 208 plantations in the state of Hidalgo in 1897, 129 were devoted to maguey. The plant is propagated from suckers and requires very little attention after transplanting to the field where it is to remain, but it takes six to eight years to mature and then yields an average of ten gallons of sap during a period of four or five months, after which it dies. " Pulque " is the fermented drink made from this sap: " mescal " is the distilled spirit made from the leaves and roots of the plant. There are other agaves used both in the production of drinks and fibres, but they are not cultivated. The " ixtle " fibres shipped from Tampico and Chiapas are all obtained from the agaves and yuccas found growing wild.

The natural and forest products of Mexico include the agave and yucca (ixtle) fibres already mentioned; the " ceibón " fibre derived from the silk-cotton tree (*Bombax pentandria*); rubber and vanilla in addition to the cultivated products; palm oil; castor beans; ginger; chicle, the gum extracted from the " chico-zapote " tree (*Achras sapota*); logwood and other dye-woods; mahogany, rosewood, ebony, cedar and other valuable woods; " cascalote " or divi-divi; jalap root (*Ipomaea*); sarsaparilla (*Smilax*); nuts and fruits.

Stock-raising dates from the earliest Spanish settlements in Mexico and received no slight encouragement from the mother country. For this reason much importance has always been attached to the industry, and stock-raising of some sort is to be found in every state of the republic, though not always to a great extent. The Spaniards found no indigenous domestic animals in the country, and introduced their own horses, cattle, sheep and swine. From these are descended the herds and flocks of to-day, with no admixture of new blood until toward the end of the 19th century. The horses and cattle are of a degenerate type, small, ungainly and inured to neglect and hard usage. The horse is chiefly used for saddle purposes and is not reared in large numbers. The mule is more generally used in every part of the country, being hardier, more intelligent and better adapted for service as a draft and pack animal. The transport of merchandise and produce was wholly by means of pack animals before the advent of railways, and is still the common means of transport away from the railway lines. For this purpose the sure-footed mule is invaluable. In some districts, however, oxen and ox-carts are employed, especially in the southern states, and always in the open, level country. The varying climatic conditions of Mexico have produced breeds of cattle that have not only departed from the original Spanish type, but likewise present strikingly different characteristics among themselves. Those of the northern plateau are small, hardy and long-lived, being bred on extensive ranges in a cooler atmosphere, and accustomed to long journeys in search of water and pasture. In the south they are larger and better nourished, owing to the permanent character of the pasturage, but are less vigorous because of the heat and insect plagues. In Yucatán the open plains, rich pasture, and comparative freedom from moist heat, insects and vampire bats, have been particularly favourable to cattle-raising, and the animals are generally rated among the best in Mexico. Notwithstanding the frequency of long, destructive droughts, cattle-raising is a preferred industry among the landowners of the northern states, and especially near the American frontier. Almost total losses are frequently experienced, but the profits of a favourable year are so great that losses seldom deter ranchers from trying again. In the sierra regions of western Chihuahua and Durango, Nuevo León, Coahuila, Aguascalientes, San Luis Potosí, and the plateau states farther south, the rainfall is more abundant and the conditions more favourable. The largest herds are to be found in Chihuahua and Durango. Above 5000 ft. the wild pasturage is short, tender and reproduces itself annually. It is exceptionally nutritious, but it disappears altogether in the dry season because of its short roots. The lowland pasture, from 2000 to 5000 ft., is composed of more vigorous grasses, with an undergrowth of an exceptionally succulent character. The stock-raiser on the border pastures his herds on the uplands during the rainy season, and on the lower pastures during the remainder of the year. Next in importance is the breeding of sheep, which is largely confined to the cooler sierra districts. They are commonly of the Spanish merino breed, and suffer in many localities on account of insufficient pasturage. Some attention is given to the breeding of goats because of the local demand for their skins, but the industry is apparently stationary. The raising of swine, however, is increasing. In the last decade of the 19th century the capital invested in these live-stock industries was estimated (by Bancroft) to exceed $700,000,000, but an official return of the 30th of June 1902 gave an aggregate valuation of only $120,523,158 (Mexican), or about £12,052,316. According to this report, which is not strictly trustworthy, there were in the republic 5,142,457 cattle, 859,217 horses, 334,435 mules, 287,991 asses, 3,424,430 sheep, 4,206,011 goats and 616,139 swine. Two years later home consumption returns noted the slaughter of 958,058 cattle (129,938 in the Federal District), 561,982 sheep, 992,263 goats and 887,130 hogs—the last item being larger than the census return of 1902. The greater part is consumed in the country, but there is a considerable export of cattle to the United States, Cuba and Central America, and of hides and skins to the United States and Europe. A few mules are sent to Central America, but the home demand usually exceeds the supply.

Other Industries.—There are no fisheries of importance except the pearl fisheries on the eastern coast of Lower California, and the tortoise fisheries on the coasts of Campeche, Yucatán, and some of the states facing the Pacific. The pearl fisheries have been worked since the arrival of the Spaniards, and were once very productive notwithstanding the primitive methods employed. Since the closing years of the last century pearl fishing in the Gulf of California has been carried on with modern appliances and better results by an English company under a concession from the government. Mother-of-pearl or abalone and other shells are also found, and, with sponges, are exported. Fishing for the tortoiseshell turtle gives employment to a large number of natives in the season, and considerable quantities of the shell are exported. Other industries of a desultory character include the collection of archil, or Spanish moss, on the western side of the Californian peninsula, hunting herons for their plumes and alligators for their skins, honey extraction (commonly wild honey), and the gathering of cochineal and ni-in insects. The cochineal insect was once an important commercial product, but the industry has fallen into decay. The "ni-in" (also known as "axe") is a small scale insect belonging to the genus *Coccus*, found in Yucatán, Oaxaca, Vera Cruz, Michoacán and other southern states, where it inhabits the spondia trees and produces a greasy substance called "ni-inea," which is much used by the natives as a varnish, especially for domestic utensils, as it resists fire as well as water.

Mining.—The best-known and most productive of the industries of Mexico is that of mining. It was the chief object of Spanish exploration, and the principal occupation of European residents and capital during three centuries of Spanish rule. Agricultural and pastoral industries gradually gained footholds here and there, and in time became important, but mining continued far in advance until near the end of the 19th century. Mines of some description are to be found in 26 of the 31 states and territories, and of these the great majority yield silver. According to the official records, there were registered in September 1906, 23,191 mining properties, of which very nearly five-sixths were described as producing silver, either by itself or in combination with other metals. The properties were classed as 1572 gold, 5461 silver, 970 copper, 383 iron, 151 mercury, 94 lead, 86 sulphur, 52 antimony, 49 zinc, 40 tin, 21 opals, 9 manganese, 6 "sal gema," 5 tourmalines, 1 bismuth and 1 turquoise—the remainder being various combinations of these minerals. The absence of coal from this list is due to the circumstance that coal mines were at that time considered as private property and were not registered under the general mining laws. A comparison with 1888–1889, when 8970 properties were registered, will show how rapidly the mining industries have been developed during that period. Besides the above, the mineral resources of Mexico include coal, petroleum, asphalt, platinum, graphite, soda and marble. In 1906 the productive mines numbered 1786, of which 491 were in Sonora, 282 in Chihuahua, 211 in Durango, 113 in Oaxaca and 105 in Nuevo León. Gold is found in Chihuahua, Durango, Guanajuato, Guerrero, Jalisco, Mexico, Morelos, Oaxaca, Puebla, Sinaloa, Sonora, Vera Cruz, Zacatecas, and to a limited extent in other states; silver in every state and territory except Campeche, Chiapas, Tabasco, Tlaxcala and the Yucatán peninsula; copper in Lower California, Guanajuato, Guerrero, Jalisco, Michoacán, Sonora, Tamaulipas and some other states; mercury chiefly in Guanajuato, Guerrero, San Luis Potosí, Vera Cruz and Zacatecas; tin in Guanajuato; coal, petroleum and asphalt in 20 states, but chiefly in Coahuila, Hidalgo, Michoacán, Oaxaca, Puebla, Sonora, Tabasco, Tamaulipas and Vera Cruz; iron in Durango, Hidalgo, Oaxaca and other states; and lead in Hidalgo, Querétaro and in many of the silver-producing districts. The most celebrated iron deposit is that of the Cerro del Mercado, in the outskirts of the city of Durango—a mountain 640 ft. in height, 1100 in breadth, and 4800 in length, reputed to be almost a solid mass of iron. Large masses of the metal are also said to exist in the sierras of Lower California. The principal coalfields that have been developed are in the vicinity of Sabinas, Coahuila. They have been opened up by American capitalists and the coal is used on the railways passing through that region. Mexican coal is of a low grade—similar to that found in Texas, but as an official geological report of 1908 estimates the supply in sight at 300,000,000 tons its industrial value to the country cannot be considered inferior to that of the precious metals. The same is true of the petroleum deposits in Tamaulipas, near Tampico, and in southern Vera Cruz. An investigation by the U.S. Geological Survey in 1909 finds that the crude Mexican oils are of low grade, but that while not equal to those found in the upper Mississippi basin for refining purposes, they furnish an excellent fuel for railway engines and other industrial purposes. Many of the Mexican railways are using these fuel oils, which are superseding imported coal. In 1909 a well was opened in the southern oilfields whose yield was equal to the best American product.

Manufactures.—Although Mexico is usually described as a non-manufacturing country, its industrial development under President Porfirio Diaz will warrant some modification of this characterization. Manufacturing for international trade has not been and may never be reached, but the industry certainly has reached the stage of meeting a great part of the home demand for manufactured goods, where the raw material can be produced in the country. There were of course some crude industries in existence before the arrival of the Spaniards, such as weaving and dyeing of fabrics made from various fibres, and making earthenware utensils, images, &c. The Spaniards introduced their own industries, including sugar-making, weaving, tanning, and leather- and metal-working, some of which still exist. The early methods of making cane sugar, clarified with clay and dried in conical moulds, are to be found all over Mexico, and the annual output of this brown or muscovado sugar (called "panela" by the natives) is still very large. The sugar crop of 1907-1908 was reported as 123,285 metric tons, in addition to which the molasses output was estimated at 70,947·5 metric tons, and "panela" at 50,000 tons. Other estimates make the "panela" output much larger, the product being largely consumed in the rural districts and never appearing in the larger markets. The estimated number of sugar mills in 1904 was about 2000, of which only about 300 were important for size and equipment. Merino sheep were introduced in 1541 and woollen manufactures date from that time. Large factories are now to be found in all parts of Mexico, and good and serviceable grades of broadcloths, cassimeres, blankets and other fabrics are turned out. There is also a considerable quantity of carpeting, underwear and hosiery manufactured. An important branch of this industry is the manufacture of "zarapes" (called "ponchos" in other parts of Spanish America)—a blanket slit in the centre for the head to pass through, and worn in place of a coat by men of the lower classes. The most important textile industry is cotton manufacture, which has become a highly successful feature in the industrial life of the republic. There were 146 factories in 1905, of which 19 were idle, and these were distributed over a very large part of the country. About one-half the raw cotton consumed was produced in Mexico, and the balance imported in fibre or as yarn. The industry is protected by a high tariff, as is also the production of raw cotton, and further encouragement is offered through a remission of internal revenue taxes where Mexican fabrics are exported for foreign consumption. The cotton factories of 1905 were equipped with 22,021 looms having 678,058 spindles, and with 38 stamping machines, employed 30,162 operatives, and turned out 13,731,638 pieces of cloth. Statistical returns, however, are somewhat incomplete and conflicting, and cannot be used with confidence. Coarse fabrics chiefly are manufactured, but the product also comprises percales, fine calicoes, ginghams, shirtings, towelings, sheetings and other kinds of goods. Considerable attention is given to the manufacture of "rebozos," the long shawls worn by women. Another very important manufacturing industry is that of tobacco, the consumption of its various products being large among all classes of the population. There were 467 tobacco factories reported in 1905 to be engaged in the manufacture of cigars, cheroots, cigarettes, snuff and cut tobaccos for the pipe. The number of factories reported for 1899 was 743, but as the consumption of leaf tobacco increased from 5,546,677 to 8,587,356 kilogrammes, it may be assumed that the decrease in factories is due to the absorption or disappearance of the small shops using old-fashioned methods. Other important manufactories are flour mills, of which there were over 500 in 1904; iron and steel works, of which there are 7 large establishments, including the immense plant at Monterey; 90 smelters for the reduction of precious metals; tanneries, potteries, and factories for the manufacture of hats, paper, linen, hammocks, harness and saddles, matches, explosives, aerated waters, soap, furniture, chocolate and sweetmeats. There are also a large number of distilleries, breweries, and establishments for the manufacture of "pulque," "mescal," and imitation or counterfeited liquors. In addition to these are the many small domestic industries, such as the making of straw hats, mats, baskets, pottery, ropes and rough textiles. The policy of the Mexican government is to encourage national manufactures, and protective duties are levied for that purpose. Other favours include exemption from taxation and exemption from import duties on machinery and raw materials. These inducements have attracted large sums of foreign capital and have brought into the country large numbers of skilled operatives, especially in the cotton, iron and steel, and smelting industries.

Constitution.—Under the Constitution of the 5th of February 1857, subsequently modified in many important particulars, the government of Mexico is described as a federation of free and sovereign states invested with representative and democratic institutions. Practically it is a Federal Republic with centralized executive powers. Its political divisions consist of 27 states (originally 19) having independent local governments, 3 territories and 1 federal district in which the national capital stands. The central government consists of three co-ordinate branches—executive, legislative and judicial—each nominally independent of the other. The executive branch consists of a president and vice-president, assisted by a cabinet of 8 secretaries of state: (1) foreign affairs; (2) interior; (3) justice; (4) public instruction and fine arts; (5) fomento, colonization and industry; (6) communications and public works; (7) finance and public credit; (8) war and marine. The president and vice-president are elected indirectly through an electoral college chosen by popular vote, and serve for a period of six years (the term was four years previous to 1904), the vice-president succeeding to the office in case of the death or permanent disability of the president. The office of vice-president was created on the 6th of May, 1904, and that official serves as president of the senate. A constitutional amendment of 1890 permits the re-election of the president without limit, the original clause prohibiting such a re-election. A candidate for the presidency must be a native-born Mexican citizen in the full exercise of his political rights, 35 years of age, not an ecclesiastic, and a resident of the republic at the time of the election. Although the authority of the president is carefully defined and limited by the Constitution, the exercise of dictatorial powers has been so common that the executive may be considered practically supreme and irresponsible. Previous to the presidency of General Porfirio Diaz in 1877 political disorders and changes in government were frequent.

The legislative branch of government consists of a Congress of two chambers—a senate and a chamber of deputies. Two ordinary congressional sessions are held each year—April 1 to May 31 and September 16 to December 15—and a permanent committee of 29 members (14 senators and 15 deputies) sits during recess, with the power to confirm executive appointments, to give assent to a mobilization of the national guard, to convene extra legislative sessions, to administer oaths, and to report at the next session on matters requiring congressional action. The senate is composed of 56 members—or two from each state and from the federal district—who are elected by popular vote for a term of four years, one-half the number retiring every two years. A senator must be not under 30 years of age, a Mexican citizen in the full enjoyment of his rights, a resident of the state he represents, and not an ecclesiastic. The chamber of deputies is composed of popular representatives, in the proportion of one deputy for each 40,000 inhabitants or fraction over 20,000, who are elected for a term of two years. A deputy must be not less than 25 years of age, other qualifications being the same as those for a senator. The salary for either senator or deputy is $3000 and that of the president $50,000. Federal officials and ecclesiastics are ineligible for election to either chamber.

Mexican citizenship includes all persons born of Mexican parents, all naturalized aliens, and all foreigners owning real estate in the republic or having children by Mexican mothers unless formal declaration is made of an intention to retain the citizenship of another country. In some cases exemptions are granted from specified taxes and military duties, otherwise naturalized citizens are treated the same as native-born. Aliens are granted the civil rights enjoyed by Mexicans, but the government reserves the right to expel those guilty of pernicious conduct. Suffrage is extended to all Mexican citizens who possess honest means of livelihood, the age limit being 18 for the married and 21 for the unmarried.

The judicial branch of the government consists of a supreme court of justice, three circuit courts, and 32 district courts. The supreme court is composed of 11 "ministros" or justices, four alternates, a "fiscal" or public prosecutor and the attorney-general—all elected by popular vote for a term of six years. It has jurisdiction in cases arising from the enforcement of the federal laws, except cases involving private interests, in admiralty cases, in cases where the republic is a party, in those between two or more states, or between a state and the citizens of another state, in those originating in treaties with foreign states, and in those affecting diplomatic and consular officials. There are likewise supreme and inferior courts in most of the states, governed by the civil and criminal codes in force in the federal district. The territories are governed by federal laws. The department of justice has oversight in matters relating to the enforcement of the federal laws and the administration of justice through minor courts. The police service is both municipal and federal in character. In some states a local police service is maintained, but in most states the federal government maintains a very efficient force of mounted "*rurales.*"

The states are organized very much like the federal government, each with its own governor, legislature, laws and judiciary. Elections are generally indirect, like those for the national executive, and official terms correspond closely to those of similar offices in the national organization. The state is nominally sovereign within its own boundaries, and the authority of its officers and courts in local questions is supreme except in cases where federal intervention or supervision is provided for by the federal constitution. The larger political divisions of the state (*partidos, distritos*, &c.) are governed by a *jefe politico*, or prefect, and the smaller by a municipal council called an *ayuntamiento*.

Defence.—The Mexican army consisted in 1908 of 2474 officers and 24,132 men, organized on modern lines, and commanded by a general staff at the capital. There were 30 battalions of infantry and 4 battalions cadres with an effective strength of 730 officers and 14,898 men; 14 regiments of cavalry and 4 regimental cadres with 493 officers and 6058 men; 2 regiments and 3 cadres of field artillery; one regiment and one cadre each of horse and mountain artillery, 4 sections of garrison artillery, and one mitrailleuse company, in all 147 officers and 1647 men; and the remainder divided among other services. Administration and headquarters staffs comprised 885 officers and 531 men. This force represented the peace footing of the army, which is recruited in part by voluntary enlistments and in part by a form of conscription that might be called impressment. Mauser rifles (1901 model) and carbines are used by the infantry and cavalry, and Schneider Canet quick-firing guns by the field and horse artillery. The nominal war strength of the army is rated at 2510 officers and 81,984 men. Factories for arms and ammunition have been established with modern machinery, and uniforms and other equipment are made in the country. The military school in the capital occupies a part of the historic castle of Chapultepec and has been thoroughly reorganized on modern lines. There is also an artillery school at Vera Cruz and subordinate schools in other parts of the republic. The national guard, to which reference is sometimes made, has no effective organization.

Mexico may be said to have no navy, the ten small vessels in commission in 1908 hardly meriting such a designation. There were 2 old despatch boats and 2 old unarmoured gunboats, a steel training cruiser, the "Zaragoza," and 5 small modern gunboats. The personnel consisted of 198 officers and 965 men. Six new cruisers were projected, but the republic has no pressing need of a navy. Small naval schools are maintained at Campeche and Mazatlán.

Education.—Education in Mexico may be said to have entered upon a progressive phase. The institutions founded by the Spaniards were wholly under ecclesiastical control. The first college in Mexico was founded during the administration of Viceroy Mendoza (1535–1550), but it taught very little beyond Latin, rhetoric, grammar and theology. The university of Mexico, planned by Mendoza and founded on the 21st of September 1551, was formally opened on the 25th of January 1553, with faculties of law, philosophy and theology. Practically nothing was done for the natives beyond oral instruction in the catechism. The university of Mexico received much support from both church and state, but it never gained a position comparable to the universities of South America—Cordoba, Lima (San Marcos) and Bogotá. The overthrow of Spanish rule in Mexico was the beginning of a new period, and efforts were made to introduce educational reforms, but the colonists and ecclesiastics were still governed by their fears and prejudices, and little was accomplished. In 1833 the university of Mexico suspended work, and in 1865 passed out of existence altogether. In 1857 the adoption of a more liberal and democratic constitution paved the way for a new period in the educational history of the country. Its realization was delayed by the wars that devastated the country down to the overthrow of Maximilian, but the leaven was at work, and with the return of peace a marked increase in the number of primary and secondary schools was noted. Colleges of law, medicine and engineering were created in Mexico City in 1865 in place of the old university and were successful from the beginning. Professional schools were also established in several of the more important provincial capitals, and everywhere increasing interest in educational matters was apparent. The best proof of this was to be found in the development of the primary schools, of which there were 8226 in 1874, with an attendance of 360,000 pupils. Of these, 603 were supported by the national government, 5240 by municipalities, 2260 by private enterprise, 117 by the Catholic church, and the remainder by Protestant denominations. Handsome schools were built in the cities and larger towns, and schools were opened in all the villages and hamlets. In some parts the natives made most creditable progress in all branches of learning. This was especially true of the Mixtecos and Zapotecas of Oaxaca, from whom have come some of the leading men of the republic. The national school laws now in force had their origin in the recommendations made by a national congress of public education convened on the 1st of December 1889, and again on the 1st of December 1890. The first result was a law regulating free and compulsory education in the federal district and national territories, which came into effect on the 17th of January 1892. From 1822 to this time the government primary schools had been under the supervision of the Compañia Lancasteriana, but they were now placed under charge of the Department of Public Education. On the 19th of May 1896 a general public education law was promulgated, which provided further regulations for the public schools, and outlined a comprehensive system. Compulsory attendance had been adopted in 1888, but did not come into effect until after the enactment of the law of 1896. It provides for uniform, free and non-sectarian primary instruction, and compulsory attendance for children of 6 to 12 years of age. Preparatory courses for professional training in the government schools were also made free and secular. As the states have control of the schools within their own boundaries there was at first a great lack of uniformity, but the national system is being generally adopted. In the official report for 1904 the number of public schools, exclusive of infant schools, was returned at 9194 (against 5843 in 1874), with an enrolment of 620,476. Of these 6488 were supported by the national and state governments and 2706 by the municipalities. The private, religious and association schools numbered 2281, with 135,838 pupils. For secondary instruction the national and state schools numbered 36 with 4642 pupils, and for professional instruction 65 with 9018 students, of whom 3790 were women. Normal schools for the training of teachers are also maintained at public expense and are giving good results. Besides these, the government maintains schools of law, medicine, agriculture and veterinary practice, engineering, mining, commerce and administration, music and fine arts. There is also a mechanics' training school (*artes y oficios*) for men and a similar school for women, schools for the blind and for deaf-mutes, reform schools, and garrison schools for soldiers. Early estimates were that 90% of the population were illiterate. In 1895 this percentage was reduced to about 84%, and the work of the schools is slowly cutting it down. Mention must be made of the National Library in Mexico City with about 225,000 volumes, and 138 public libraries (in 1904) in other parts of the republic, 34 museums for scientific, educational and art purposes, and 11 meteorological observatories. Newspapers and periodicals, whose educational value varies widely, numbered 459 in 1904, of which 439 were in Spanish and 12 in English.

Religion.—The people of Mexico are almost wholly of the Roman Catholic faith, the census of 1900 returning 13,533,013 communicants of that church, 51,795 Protestants (in great part foreigners), 3811 of other faiths, and 18,640 of no faith. The constitution of 1857 grants toleration to all religions, and since 1868 several Protestant denominations have established missions in the towns, but their numbers are still comparatively small. The Roman Catholic religion was enforced at the time of the conquest, but a large percentage of the natives may still be considered semi-pagan, the gods of their ancestors being worshipped in secret, and the forms and tenets of the dominant faith, which they but faintly comprehend, being largely adulterated with superstitions and practices of pagan origin. The church hierarchy consists of 3 archbishops and 23 suffragan bishops. It dates from the creation of the bishopric of Mexico in 1530, with Fray Juan de Zumárraga as bishop, although two previous creations had been proclaimed at Rome, that of Yucatán in 1518 and Puebla in 1525. In 1545 the bishopric of Mexico was elevated to an archbishopric, which in 1863 was divided into three archdioceses—Mexico, Michoacán and Guadalajara. An Inquisition tribunal was established in the capital in 1571, and in 1574 its first *auto-da-fé* was celebrated with the burning of "twenty-one pestilent Lutherans." The Inquisition was active in Mexico during two and a half centuries, and was finally suppressed on the 31st of May 1820. The great power exercised by the Roman Catholic church during the colonial period enabled it not only to mould the spiritual belief of the whole people, but also to control their education, tax their industries, and shape the political policies governing their daily life. In this way it acquired great wealth, becoming the owner of extensive estates in every part of the country and of highly productive properties in the towns. It was said in 1859 that the church owned one-third of the real and personal property of the republic. The reform laws of that year nationalized its property, abolished its numerous orders and institutions and deprived it of state support and of all participation in political affairs. Subsequent legislation removed clerical influence from public instruction, made marriage a civil ceremony and closed all conventual establishments. The church still exercises a boundless influence over the Mexican lower classes, and is still the most influential organization in the republic.

Finance.—The national revenues are derived from import and export duties, port dues and other taxes levied on foreign commerce; from excise and stamp taxes and other charges upon internal business transactions; from direct taxes levied in the federal district and national territories, covering a land tax in rural districts, a house tax in the city, commercial and professional licences, water rates, and sundry taxes on bread, pulque, vehicles, saloons, theatres, &c.; from probate dues and registry fees; from a surcharge on all taxes levied by the states, called the "federal contribution," which is paid in federal revenue stamps; from post and telegraph receipts; and from some minor sources of income. The most fruitful revenue is the duty on imports, which is sometimes used for the protection of national industries, and which yields from 40 to 45% of the total receipts. The excise taxes in 1905 were levied on tobacco, alcohol and alcoholic beverages, and on cotton goods. Mining taxes, which are subject to periodic changes, consist of an initial or registry tax on the claim (*pertenencia*), an annual or rental tax on each claim, and a tax of 3½% (1905) on the export of unrefined gold and silver, 2½% on partially refined ores, and 1½% on pure silver. The expenditures are chiefly for the services of the public debt, military expenses, public works and internal affairs (Department of the Interior). The public debt service alone required $26,201,873 (£2,620,187) in 1908.

For the fiscal year 1906–1907 the revenue produced a total of 114,286,122 *pesos* (dollars), or, approximately, £11,428,612, and the expenditure was 85,076,641 *pesos*, or £8,507,664. The estimates for 1908–1909 show a marked decline owing to the commercial depression, the revenue being computed at 103,385,000 *pesos*, and the expenditure at 103,203,830 *pesos*. Of the former 46,500,000 *pesos* are credited to import duties, 31,930,000 *pesos* to stamps, excise taxes, &c., 10,930,000 *pesos* to direct taxes, and the balance to various sources. Owing to the circumstance that the great majority of the Mexican people own no property, carry on no industry, and are not even to be considered regular productive labourers, the revenues are small in relation to the population and are comparatively inelastic.

The revenues and expenditures of the states and municipalities in 1904, the latest date available, aggregated as follows:—

	Revenue.	Expenditure.
States	24,519,926 pesos	23,557,968 pesos
Municipalities . . .	14,605,022 ,,	14,160,132 ,,

The taxes cover a great variety of occupations and property, often to a minute and vexatious degree, and the expenditure includes the expenses of local administration, schools, police, streets and other objects of purely local interest.

The public indebtedness of Mexico includes a foreign debt payable in gold, an internal debt payable in silver, and a floating debt covering unpaid balances on appropriations, unpaid interest, and other credits and obligations. The paper money issues are by banks and not by the government, and the national treasury keeps no cash in its vaults and has no sinking funds to offset this indebtedness. The foreign debt dates from 1825, when £10,000,000 were borrowed in London through two loans. Interest defaults led to a conversion of the debt in 1851, the interest rate being reduced from 5% to 3%. Further defaults followed and in 1888 another adjustment was made by the issue of 6% gold-bearing bonds. From this time the Mexican government has met its obligations promptly, in consequence of which its credit is rated high and its bonds have even been quoted at a premium. In 1899 the government placed a loan of £22,700,000 in Europe at 5% for the conversion of its 6% bonds, securing it by the hypothecation of 62% of its import and export duties. Further loans have considerably increased the debt since then, but it is still within the normal resources of the country. According to Matias Romero (*Mexico and the United States*, 1898), a new type of indebtedness was inaugurated in 1850 in the shape of an internal debt payable in silver. Other loans and obligations contracted during periods of disorder were afterwards consolidated under this type, and later on unpaid railway subsidies were also included. The rate of interest is from 3% to 5%, and both principal and interest are payable in silver. The rapid development of railway construction has largely increased this part of the public debt, the revenues of the country being insufficient to meet the subsidy obligations, but as the railways are built for the development of valuable resources and the opening of needed trade communications, the increase has occasioned no loss of credit. At the end of 1908 the total public indebtedness of the republic was:—

Foreign, or gold debt, including City of Mexico loan . . .		£30,927,348
Internal, or silver debt . . .	$130,892,100	
Floating debt	860,495	
	$131,752,595 or	£13,175,259
Total		£44,102,607

The fiscal or tax valuation of property throughout the republic in 1904 was computed to be—the fiscal value being two-thirds of the real value:—

Urban	$312,950,983
Rural	488,182,009
Federal District	252,716,454
Total	$1,053,849,446

Previous to 1905 all monetary transactions in Mexico were based in practice on a fluctuating silver standard and free coinage. By a law of the 9th of December 1904, promulgated by an executive decree of the 25th of March 1905, the gold standard was adopted, and the silver *peso*, ·9027 fine and containing 24·438 grammes of pure silver, was made the monetary unit with a valuation of ·75 grammes of gold. At the same time the free coinage of silver was suspended, the government reserving to itself the sole privilege of coining money. The coinage of Mexico, now concentrated at the mint in the capital (all others having been closed) is based (since November 28, 1867) on the decimal system—the *peso* being divided into 100 *centavos*—and consists of gold, silver, nickel and bronze coins, whose weight and fineness are determined by the monetary law of 1904. The coins minted under this law are:—

GOLD: 10 *pesos*, ·900 fine, weighing 8·333⅓ grammes.
5 *pesos*, ,, ,, ,, 4·116⅔ ,,
(the first called a "hidalgo" and the second a "medio hidalgo").

SILVER: 1 *peso*, ·9027 fine, containing 24·438 grammes of pure silver,
50 *centavos*, ·800 fine,
20 " " "
10 " " "
NICKEL: 5 "
BRONZE: 1 and 2 *centavos*, 95 parts copper , 4 tin, 1 zinc.

Provisions are also made for continuing the coinage of "trade dollars" for export, which have a wide circulation in the Orient but are not current at home. Fractional silver coin is not legal tender above 20 *pesos*, and bronze and nickel coins not above 1 *peso*, but the government maintains conversion offices where such coins can be converted into silver *pesos* without loss. The amount of gold in circulation is small, the bank notes convertible into gold taking its place. Foreign coins are permitted to circulate in the republic.

There were 34 chartered banks in Mexico in 1908, of which 29 enjoyed the privilege of issuing bank notes; the total note circulation on the 31st of December 1906 was 97,787,878 *pesos*. These note issues are everywhere current at full nominal value, being secured under the provisions of the national banking law of 1896 by metallic reserves. The notes are not legal tender, and it is forbidden to count them as "cash on hand" in bank returns, but ample safeguards both as to issue and redemption inspire full confidence in their employment as a substitute for gold. Restrictions on speculative operations in real estate and on the use of hypothecated and discounted paper as security for other transactions, together with the publication of detailed monthly balance sheets, have kept these banks free from unsound methods, and their record thus far (1909) has been conspicuously good. Mortgage and loan banks have also been established in accordance with the law of 1896, and are subject to official supervision. Private banks are numerous, but foreign banks are not encouraged to open agencies. The use of cheques is very limited because of the stamp tax.

Weights and Measures.—Mexico adopted the metric system in 1862, and it is used in all official transactions, land measurements, railway calculations and public school work. The old Spanish weights and measures, modified in many particulars, continued in private use, however, and in 1895 it became necessary to declare the metric system the only legal system and to make its use compulsory after the 16th of September 1896.

BIBLIOGRAPHY.—The historical student will find valuable material in Bernal Diaz del Castillo, *Crónica de la conquista de Nueva España* (Madrid, 1632, and other dates); Antonio Herrera *História generál de los hechos de los Castellános en las islas y tierra firma del mar oceáno* (4 vols., Madrid, 1601); F. C. Mac Nutt, *Letters of Cortés to Charles V.* (London, 1908); W. H. Prescott, *Conquest of Mexico* (3 vols., London, 1845); and the works of Gomara, Helps, Kingsborough, Las Casas, Sahagun and Justin Winsor.

HISTORY

I.—Ancient Mexico.

The name Mexico is connected with the name of the group of American tribes calling themselves *Mexica* (sing. *Mexicatl*) or *Azteca*. The word is related to or derived from the name of the Mexican national war-god, Mexitl, better known as Huitzilopochtli. The Aztecs from the 12th century appear to have migrated from place to place over the mountain-walled plateau of *Anahuac*, the country "by the water," so called from its salt lagoons, which is now known as the Valley of Mexico. About 1325 they founded on the lake of Tezcuco the permanent settlement of Mexico Tenochtitlan, which is still represented by the capital city, Mexico. The name Mexico[1] was given by the Spanish conquerors to the group of countries over which the Aztec power more or less prevailed at the time of the European invasion. Clavigero (*Storia antica del Messico*, vol. i.) gives a map of the so-called "Mexican empire," which may be roughly described as reaching from the present Zacatecas to beyond Guatemala; it is noticeable that both these names are of Mexican origin, derived respectively from words for "straw" and "wood." Eventually Mexico and New Mexico came to designate the still vaster region of Spanish North America, which (till cut down by changes which have limited the modern republic of Mexico) reached as far as the Isthmus of Panama on the south and took in California and Texas on the north. Mexico in this wide sense is of high interest to the anthropologist from the several native American civilizations which appear within its limits, and which conveniently if loosely group themselves round two centres, the Mexican proper and the Central American.

When early in the 16th century the Spaniards found their way from the West India Islands to this part of the mainland of America, they discovered not rude and simple tribes like the islanders of the Antilles, but nations with armies, official administrators, courts of justice, high agriculture and mechanical arts, and, what struck the white men especially, stone buildings whose architecture and sculpture were often of dimensions and elaborateness to astonish the builders and sculptors of Europe. Here was a problem which excited the liveliest curiosity and gave rise to a whole literature. Hernandez and Acosta shared the opinion of their time that the great fossil bones found in Mexico were remains of giants, and that, as before the deluge there were giants on the earth, therefore Mexico was peopled from the Old World in antediluvian times. On the other hand the multitude of native American languages suggested that the migration to America took place after the building of the tower of Babel, and Siguenza arrived at the curiously definite result that the Mexicans were descended from Naphtuhim, son of Mizraim and grandson of Noah, who left Egypt for Mexico shortly after the confusion of tongues. Although such speculations have fallen out of date, they induced the collection of native traditions and invaluable records of races, languages and customs, which otherwise would have been lost for ever. Even in the 19th century Lord Kingsborough spent a fortune in printing a magnificent compilation of Mexican picture-writings and documents in his *Antiquities of Mexico* to prove the theory advocated by Garcia a century earlier, that the Mexicans were the lost tribes of Israel. Modern archaeologists approach the question from a different standpoint, but the origin of the American aborigines and of Mexican civilization remains extremely obscure (see AMERICA, where the primitive Mexican cultures are fully illustrated, and CENTRAL AMERICA).

Real information as to the nations of Mexico before Spanish times is very imperfect, but not altogether wanting. The accurate and experienced Alexander von Humboldt considered the native Americans of both continents to be substantially similar in race-characters. Such a generalization will become sounder, if, as is now generally done by anthropologists, the Eskimo with their pyramidal skulls, dull complexion and flat noses are removed into a division by themselves. Apart from these polar nomads, the American indigenes group roughly into a single division of mankind, of course with local variations. If our attention is turned to the natives of Mexico especially, the unity of type will be found particularly close. The native population of the plateau of Mexico, mainly Aztecs, may still be seen by thousands without any trace of mixture of European blood. Their stature is estimated to be about 5 ft. 3 in., but they are of muscular and sturdy build. Measurements of their skulls show them mesocephalic (index about 78), or intermediate between the dolichocephalic and brachycephalic types of mankind. The face is oval, with low forehead, high cheek-bones, long eyes sloping outward towards the temples, fleshy lips, nose wide and in some cases flattish but in others aquiline, coarsely moulded features, with a stolid and gloomy expression. Thickness of skin, masking the muscles, has been thought the cause of a peculiar heaviness in the outlines of body and face; the complexion varies from yellow-brown to chocolate (about 40 to 43 in the anthropological scale); eyes black; straight coarse glossy black hair; beard and moustache scanty. Among variations from this type may be mentioned higher stature in some districts, and lighter complexion in Tehuantepec and elsewhere. If now the native Americans be compared with the races of the regions across the oceans to their east and west, it will be seen that their unlikeness is extreme to the races eastward of them, whether white Europeans or black Africans. On the other hand they are considerably like the Mongoloid peoples of north and east Asia (less so to the Polynesians); so that the general tendency among anthropologists has been to admit a common origin, however remote, between the tribes of Tartary and of America. This original connexion, if it may be accepted, would seem to belong to a long-past period, to judge from the failure of all attempts to discover an affinity between the languages of America and Asia. At whatever date the Americans began to people America, they must have had time to import or develop the numerous families of languages actually found there, in none of which has community of origin been satisfactorily proved with any other language-group at home or abroad. In Mexico itself the languages of the Nahua nations, of which the Aztec is the best-known dialect, show no connexion of origin with the language of the Otomi tribes, nor either of these with the languages of the regions of the ruined cities of Central America, the Quiché of Guatemala and the Maya of Yucatan. The remarkable phenomenon of nations so similar in bodily make but so distinct in language can hardly be met except by supposing a long period to have elapsed since the country was first inhabited by the ancestors of peoples whose language has since passed into so different forms. The original peopling of America might then well date from the time when there was continuous land between it and Asia.

---

[1] In this, as in all other Aztec names, the *x* (or *j*) represents the English sound *sh*; hence *Mexitli* and *Mexico* should be properly pronounced *Meshitli*, *Meshico*. But they do not appear to have ever been so pronounced by the Spaniards, who naturally gave to the *x* its ordinary Spanish sound of the German *ch*.

It would not follow, however, that between these remote ages and the time of Columbus no fresh immigrants can have reached America. We may put out of the question the Scandinavian sea-rovers who sailed to Greenland about the 10th century. But at all times communication has been open from east Asia, and even the South Sea Islands, to the west coast of America. The importance of this is evident when we consider that late in the 19th century Japanese junks still drifted over by the ocean current to California at the rate of about one a year, often with some of the crew still alive. Further north, the Aleutian islands offer a line of easy sea passage, while in north-east Asia, near Bering's Strait, live Chukchi tribes who carry on intercourse with the American side. Moreover there are details of Mexican civilization which are most easily accounted for on the supposition that they were borrowed from Asia. They do not seem ancient enough to have to do with a remote Asiatic origin of the nations of America, but rather to be results of comparatively modern intercourse between Asia and America. Humboldt (*Vues des Cordillères*, Pl. xxiii.) compared the Mexican calendar with that in use in eastern Asia. The Mongols, Tibetans, Chinese and other neighbouring nations have a cycle or series of twelve animals, viz. rat, bull, tiger, hare, dragon, serpent, horse, goat, ape, cock, dog, pig, which may possibly be an imitation of the ordinary Babylonian-Greek zodiac familiar to ourselves. The Mongolian peoples not only count their lunar months by these signs, but they reckon the successive days by them, rat-day, bull-day, tiger-day, &c., and also, by combining the twelve signs in rotation with the elements, they obtain a means of marking each year in the sixty-year cycle, as the wood-rat year, the fire-tiger year, &c. This method is highly artificial, and the reappearance of its principle in the Mexican and Central American calendar is suggestive of importation from Asia. Humboldt also discussed the Mexican doctrine of four ages of the world belonging to water, earth, air and fire, and ending respectively by deluge, earthquake, tempest and conflagration. The resemblance of this to some versions of the Hindu doctrine of the four ages or yuga is hardly to be accounted for except on the hypothesis that the Mexican theology contains ideas learnt from Asiatics. Among Asiatic points of resemblance to which attention has since been called is the Mexican belief in the nine stages of heaven and hell, an idea which nothing in nature would suggest directly to a barbaric people, but which corresponds to the idea of successive heavens and hells among Brahmans and Buddhists, who apparently learnt it (in common with our own ancestors) from the Babylonian-Greek astronomical theory of successive stages or concentric planetary spheres belonging to the planets, &c. The Spanish chronicles also give accounts of a Mexican game called *patolli*, played at the time of the conquest with coloured stones moved on the squares of a cross-shaped figure, according to the throws of beans marked on one side; the descriptions of this rather complicated game correspond closely with the Hindu backgammon called *pachisi* (see Tylor in *Jour. Anthrop. Inst.*, viii. 116).

The native history of Mexico and Central America is entitled to more respect than the mere recollections of savage tribes. The Mexican pictures so far approached writing proper as to set down legibly the names of persons and places and the dates of events, and at least helped the professional historians to remember the traditions repeated orally from generation to generation. Thus actual documents of native Aztec history, or copies of them, are still open to the study of scholars, while after the conquest interpretations of these were drawn up in writing by Spanish-educated Mexicans, and histories founded on them with the aid of traditional memory were written by Ixtilxochitl and Tezozomoc. In Central America the rows of complex hieroglyphs to be seen sculptured on the ruined temples probably served a similar purpose. The documents written by natives in later times thus more or less represent real records of the past, but the task of separating myth from history is of the utmost difficulty. Among the most curious documents of early America is the *Popol-Vuh* or national book of the Quiché kingdom of Guatemala, a compilation of traditions written down by native scribes, found and translated by Father Ximenez about 1700, and published by Scherzer (Vienna, 1857) and Brasseur de Bourbourg (Paris, 1861). This book begins with the time when there was only the heaven with its boundaries towards the four winds, but as yet there was no body, nothing that clung to anything else, nothing that balanced itself or rubbed together or made a sound; there was nought below but the calm sea alone in the silent darkness. Alone were the Creator, the Former, the Ruler, the Feathered Serpent, they who give being and whose name is Gucumatz. Then follows the creation, when the creators said "Earth," and the earth was formed like a cloud or a fog, and the mountains appeared like lobsters from the water, cypress and pine covered the hills and valleys, and their forests were peopled with beasts and birds, but these could not speak the name of their creators, but could only chatter and croak. So man was made first of clay, but he was strengthless and senseless and melted in the water; then they made a race of wooden mannikins, but these were useless creatures without heart or mind, and they were destroyed by a great flood and pitch poured down on them from heaven, those who were left of them being turned into the apes still to be seen in the woods. After this comes the creation of the four men and their wives who are the ancestors of the Quichés, and the tradition records the migrations of the nation to Tulan, otherwise called the Seven Caves, and thence across the sea, whose waters were divided for their passage. It is worth while to mention these few early incidents of the national legend of Guatemala, because their Biblical incidents show how native tradition incorporated matter learnt from the white men. Moreover, this Central American document, mythical as it is, has an historical importance from its bringing in names belonging also to the traditions of Mexico proper. Thus Gucumatz, "Feathered Serpent" corresponds in name to the Mexican deity Quetzalcoatl; Tulan and the Seven Caves are familiar words in the Aztec migration traditions, and there is even mention of a chief of Toltecat, a name plainly referring to the famed Toltecs. Thus the legends of the *Popol-Vuh* confirm what is learnt from comparing the culture of Central America and Mexico proper, that, though these districts were not connected by language, the intercourse between them had been sufficient to justify the anthropologist in including both districts in one region. Historical value of the ordinary kind may be found in the latter part of the *Popol-Vuh*, which gives names of chiefs down to the time when they began to bear Spanish names and the great city of Quiché became the deserted ruin of Santa Cruz. The Maya district of Yucatan has also some vestiges of native traditions in the manuscript translated by D. Pio Perez (in Stephens, *Incidents of Travel in Yucatan*) and in the remarkable 16th century *Relacion de las cosas de Yucatan* by Diego de Landa, published by Brasseur de Bourbourg (Paris, 1864). As in the Guatemala traditions, we hear of ancient migration from the Mexican legendary region of Tula; and here the leaders are four famous chiefs or ancestors who bear the Aztec name of the Tutul-Xiu, which means "Bird-Tree." Unfortunately for the historical standing of these four ancestors, there are in the Aztec picture-writings representations of four trees, each with a bird perched on it, and placed facing the four quarters, which make it probable that the four Tutul-Xiu of tradition may be only mythic personifications of the four cardinal points (see Schultz-Sellack in *Zeitschr. f. Ethn.*, 1879, p. 209). Nevertheless, part of the later Maya records may be genuine—for instance, when they relate the war about three centuries before the Spanish conquest, when the king of Chichen-Itza destroyed the great city of Mayapan. Though the Central American native kings have too little interest for traditions of them to be dwelt on here, they bring into view one important historical point—that the ruined cities of this region are not monuments of a forgotten past, but that at least some of them belong to history, having been inhabited up to the conquest, apparently by the very nations who built them.

Turning now to the native chronicles of the Mexican nations, these are records going back to the 12th or 13th century, with some vague but not worthless recollections of national events from times some centuries earlier. These traditions, in some measure borne out by linguistic evidence of names, point to the immigration of detachments of a widespread race speaking a common language, which is represented by the Aztec, still a spoken language in Mexico. This language was called *nahuatl*, and one who spoke it as his native tongue was called *nahuatlacatl*, so that modern anthropologists are following native precedent when they use the term *Nahua* for the whole series of peoples now under consideration. Earliest of the Nahua nations, the Toltecs are traditionally related to have left their northern home of Huehuetlapallan in the 6th century; and there is other evidence of the real existence of the nation. Their name *Toltecatl* signifies an inhabitant of *Tollan* (land of reeds), a place which has a definite geographical site in the present Tulan or Tula, north of the valley of Anahuac, where a Toltec kingdom seems to have had its centre. To this nation was due the introduction of maize and cotton into Mexico, the skilful workmanship in gold and silver, the art of building on a scale of vastness still witnessed to by the mound of Cholula, said to be Toltec work, and the Mexican hieroglyphic writing and calendar. With the Toltecs is associated the tradition of Quetzalcoatl, a name which presents itself in Mexican religion as that of a great deity, god of the air, and in legend as that of a saintly ruler and civilizer. His brown and beardless worshippers describe him as of another race, a white man with noble features, long black hair and full beard, dressed in flowing robes. He came from Tulan or from Yucatan (for the stories differ widely), and dwelt twenty years among them, teaching men to follow his austere and virtuous life, to hate all violence and war, to sacrifice no men or beasts on the altars, but to give mild offerings of bread and flowers and perfumes, and to do penance by the votaries drawing blood with thorns from their own bodies. Legend tells stories of his teaching men picture-writing and the calendar, and also the artistic work of the silversmith, for which Cholula was long famed; but at last he departed, some say towards the unknown land of Tlapallan, but others to Coatzacoalcos on the Atlantic coast on the confines of Central America, where native tradition still keeps up the divine names of Gucumatz among the Quichés and Cukulcan among the Mayas, these names have the same meaning as Quetzalcoatl in Aztec, viz. "Feathered Serpent." Native tradition held that when Quetzalcoatl reached the Atlantic he sent back his companions to tell the Cholulans that in a future age his brethren, white men and bearded like himself, should land there from the sea where the sun rises and come to rule the country. That there is a basis of reality in the Toltec traditions is shown by the word *toltecatl* having become among the later Aztecs a substantive signifying an artist or skilled craftsman. It is further related by the Mexican historians that the Toltec nation all but perished in the 11th century by years of drought, famine and pestilence, a few only of the survivors remaining in the land, while the rest migrated into Yucatan and Guatemala. After the Toltecs came the Chichimecs, whose name, derived from *chici*, dog, is applied to many rude tribes; they are said to have come from Amaquemecan under a king named Xolotl, names which being Aztec imply that the nation was Nahua; at any rate they appear afterwards as fusing with more cultured Nahua nations in the neighbourhood of Tezcuco. Lastly is recorded the Mexican immigration of the seven nations, Xochimilca, Chalca, Tepaneca, Acolhua, Tlahuica, Tlascalteca, Azteca. This classification of the Nahuatlac tribes has a meaning and value. It is true that Aztlan, the land whence the Aztecs traced their name and source, cannot be identified, but the later stages of the long Aztec migration seem historical, and the map of Mexico still shows the names of several settlements recorded in the curious migration map, published by Gemelli Careri (*Giro del mondo*, Venice, 1728) and commented on by Humboldt; among these local names are Tzompanco, "place of skulls," now Zumpango in the north of the Mexican valley, and Chapultepec, "grasshopper hill," now a suburb of the city of Mexico itself, where the Aztecs are recorded to have celebrated in 1195 the festival of tying up the "bundle of years" and beginning a new cycle.

The Aztecs moving from place to place in Anahuac found little welcome from the Nahua peoples already settled there. One of the first clear events of the Aztec arrival is their being made tributary by the Tepanecs, in whose service they showed their warlike prowess in the fight near Tepeyacac, where now stands the famous shrine of Our Lady of Guadalupe. Thus they overcame the Acolhuas, who had made Tezcuco a centre of prosperity. By the 13th century the Aztecs by their ferocity had banded their neighbours together against them; some were driven to take refuge on the reedy lake shore at Acoculco, while others were taken as captives into Culhuacan. The king of this district was Coxcoxtli, whose name has gained an undeserved reputation even in Europe as "Coxcox, the Mexican Noah," from a scene in the native picture-writing where his name appears together with the figure of a man floating in a dug-out tree, which has been mistaken even by Humboldt for a representation of the

Mexican deluge-myth. Coxcoxtli used the help of the Aztecs against the Xochimilco people; but his own nation, horrified at their bloodthirsty sacrifice of prisoners, drove them out to the islands and swamps of the great salt lagoon, where they are said to have taken to making their *chinampas* or floating gardens of mud heaped on rafts of reeds and brush, which in later times were so remarkable a feature of Mexico. As one of the Aztec chiefs at the time of the founding of their city was called Tenoch, it is likely that from him was derived the name Tenochtitlan or "Stone-cactus place." Written as this name is in pictures or rebus, it probably suggested the invention of the well-known legend of a prophecy that the war-god's temple should be built where a prickly pear was found growing on a rock, and perched on it an eagle holding a serpent; this legend is still commemorated on the coins of Mexico. Mexico-Tenochtitlan, founded about 1325, for many years afterwards probably remained a cluster of huts, and the higher civilization of the country was still to be found, especially among the Acolhuas in Tezcuco. The wars of this nation with the Tepanecs, which went on into the 15th century, were merely destructive, but larger effects arose from the expeditions under the Culhua king Acamapichtli, where the Aztec warriors were prominent, and which extended far outside the valley of Anahuac. Especially a foray southward to Quauhnahuac, now Cuernavaca, on the watershed between the Atlantic and Pacific, brought goldsmiths and other craftsmen to Tenochtitlan, which now began to rise in arts, the Aztecs laying aside their rude garments of aloe-fibre for more costly clothing, and going out as traders for foreign merchandise. In the 14th century the last great national struggle took place. The Acolhuas had at first the advantage, but Ixtlilxochitl did not follow up the beaten Aztecs but allowed them to make peace, whereupon, under professions of submission, they fell upon and sacked the city of Tezcuco. The next king of Tezcuco, Nezahualcoyotl, turned the course of war, when Azcapuzalco, the Tepanec stronghold, was taken and the inhabitants sold as slaves by the conquering Acolhuas and Aztecs; the place thus degraded became afterwards the great slave-market of Mexico. In this war we first meet with the Aztec name Moteuczoma, afterwards so famous in its Spanish form Montezuma. About 1430 took place the triple alliance of the Acolhua, Aztec and Tepanec kings, whose capitals were Tezcuco, Mexico and Tlacopan, the latter standing much below the other two. In fact the rest of native history may be fairly called the Aztec period, notwithstanding the magnificence and culture which make Tezcuco celebrated under Nezahualcoyotl and his son Nezahualpilli. When the first Moteuczoma was crowned king of the Aztecs, the Mexican sway extended far beyond the valley plateau of its origin, and the gods of conquered nations around had their shrines set up in Tenochtitlan in manifest inferiority to the temple of Huitzilopochtli, the war-god of the Aztec conquerors. The rich region of Quauhnahuac became tributary; the Miztec country was invaded southward to the Pacific, and the Xicalanca region to what is now Vera Cruz. It was not merely for conquest and tribute that the fierce Mexicans ravaged the neighbour-lands, but they had a stronger motive than either in the desire to obtain multitudes of prisoners whose hearts were to be torn out by the sacrificing priests to propitiate a pantheon of gods who well personified their bloodthirsty worshippers. (E. B. T.)

Ancient Civilization.

Government.

While the prairie tribes of America lived under the loose sway of chiefs and councils of old men, the settled nations of Mexico had attained to a highly organized government. This may be seen by the elaborate balance of power maintained in the federation of Mexico, Tezcuco and Tlacopan, where each king was absolute in his own country, but in war or other public interests they acted jointly, with powers in something like the proportion in which they divided conquered lands and spoil, which was two-fifths each to Mexico and Tezcuco and one-fifth to Tlacopan. The successor of the Aztec king was customarily a chosen brother or nephew, the eldest having the first claim unless set aside as incompetent; this mode of succession, which has been looked on as an elaborate device for securing practical advantages, seems rather to have arisen out of the law of choice among the descendants of the female line, found in American tribes of much lower culture. Something like this appears in the succession of kings of Tezcuco and Tlacopan, which went to sons by the principal wife, who was usually of the Aztec royal family. The Mexican chronicles, however, show instances of the king's son succeeding or of powerful chiefs being elected to the kingship. The term republic is sometimes used to describe the little state of Tlascala, but this was in fact a federation of four chiefs, with an assembly of nobles. In the Zapotec district the Wiyatao or high-priest of Zopaa was a divine ruler before whom all prostrated themselves with faces to the ground; he was even too sacred to allow his foot to touch the earth, and was only seen carried in a litter.

Palaces, &c.

The accounts of the palaces of the native kings must be taken with some reserve, from the tendency to use descriptive terms not actually untrue, but which convey erroneous ideas taken from European architecture; thus what are called columns of porphyry and jasper supporting marble balconies might perhaps be better described as piers carrying slabs, while the apartments and terraces must have been more remarkable for number and extent than architectural grandeur, being but low one-storied buildings. The principal palace of Mexico consisted of hundreds of rooms ranged round three open squares, of such extent that one of the companions of Cortes records having four times wandered about till he was tired, without seeing the whole. Not less remarkable was the palace of Tezcuco, surrounded with its groves and pleasure-gardens; and, though now hardly anything remains of the buildings above ground, the neighbouring hill of Tezcotzinco still has its stone steps and terraces; and the immense embankment carrying the aqueduct-channel of hewn stone which supplied water to basins cut in the solid rock still remains to prove that the chroniclers' descriptions, if highly coloured, were at any rate genuine. Till the 18th century the gigantic figures of Axayacatl and his son Montezuma were to be seen carved in the porphyry hill of Chapultepec, but these as well as the hanging gardens have been destroyed, and only the groves of *ahuehuete* (cypress) remain of the ancient beauties of the place. That in the palace gardens flowers from the *tierra caliente* were transplanted, and water-fowl bred near fresh and salt pools fit for each kind, that all kinds of birds and beasts were kept in well-appointed zoological gardens, where there were homes even for alligators and snakes—all this testifies to a cultivation of natural history which was really beyond the European level of the time. From the palaces and retinues of thousands of servants attached to the royal service may be inferred at once the despotic power of the Mexican rulers and the heavy taxation of the people; in fact some of the most remarkable of the picture-writings are tribute-rolls enumerating by hundreds and thousands the mantles, ocelot-skins, bags of gold-dust, bronze hatchets, loads of chocolate, &c., furnished periodically by the towns. Below the king was a numerous and powerful class of nobles, the highest of whom (*tlatoani*) were great vassals owing little more than homage and tribute to their feudal lord, while the natural result of the unruliness of the noble class was that the king to keep them in check increased their numbers, brought them to the capital as councillors, and balanced their influence by military and household officers, and by a rich and powerful merchant class. The nobles not only had privileges of rank and dignity, but substantial power over the plebeian or peasant class (*macehualli*). The greatest estates belonged to the king, or had been granted to military chiefs whose sons succeeded them, or were the endowments of temples, but the *calpulli* or village community still survived, and each freeman of the tribe held and tilled his portion of the common lands. Below the freemen were the slaves, who were war-captives, persons enslaved for punishment, or children sold by their parents. Prisoners of war were mostly doomed to sacrifice, but other classes of slaves were mildly treated, retaining civil rights, and their children were born free.

Justice.

The superior courts of law formed part of the palace, and there were tribunals in the principal cities, over each of which presided a supreme judge or *cihuacoatl*, who was irremovable, and whose criminal decisions not even the king might reverse; he appointed the lower judges and heard appeals from them; it is doubtful whether he judged in civil cases, but both kinds of suits were heard in the court below, by the *tlacatecatl* and his two associates, below whom were the ward-magistrates. Lands were set apart for the maintenance of the judges, and indeed nothing gives a higher idea of the elaborate civilization of Mexico than this judicial system, which culminated in a general court and council of state presided over by the king. The laws and records of suits were set down in picture-writings, of which some are still to be seen; sentence of death was recorded by drawing a line with an arrow across the portrait of the condemned, and the chronicles describe the barbaric solemnity with which the king passed sentence sitting on a golden and jewelled throne in the divine tribunal, with one hand on an ornamented skull and the golden arrow in the other. Among the resemblances to old-world law was the use of a judicial oath, the witness touching the ground with his finger and putting it to his lips, thus swearing by Mother Earth. The criminal laws were of extreme severity, even petty theft being punished by the thief being enslaved to the person he had robbed, while to steal a tobacco pouch or twenty ears of corn was death; he who pilfered in the market was then and there beaten to death, and he who insulted Xipe, the god of the gold- and silversmiths, by stealing his precious metal, was skinned alive and sacrificed to the offended deity. Though aloe-beer or "pulque" was allowed for feasts and to invalids in moderation, and old people over seventy seem to be represented in one of the picture-writings as having liberty of drunkenness, young men found drunk were clubbed to death and young women stoned. For such offences as witchcraft, fraud, removing landmarks, and adultery the criminal had his heart cut out on the altar, or his head crushed between two stones, while even lesser punishments were harsh, such as that of slanderers, whose hair was singed with a pine-torch to the scalp.

War. Based on conquest as the Aztec kingdom was, and with the most bloodthirsty religion the world ever saw, the nation was, above all, a fighting community. To be a tried soldier was the road to honour and office, and the king could not be enthroned till he had with his own hand taken captives to be butchered on the war-god's altar at his coronation. The common soldiers were promoted for acts of daring, and the children of chiefs were regularly trained to war, and initiated by being sent into battle with veterans, with whose aid the youth took his first prisoner, but his future rise depended on how many captives he took unaided in fight with warlike enemies; by such feats he gained the dignity of wearing coloured blankets, tassels and lip-jewels, and reached such military titles as that of "guiding eagle." The Mexican military costumes are to be seen in the picture-writings, where the military orders of princes, eagles and tigers are known by their braided hair, eagles' beaks and spotted armour. The common soldiers went into battle brilliant in savage war-paint, but those of higher rank had helmets like birds and beasts of prey, armour of gold and silver, wooden greaves, and especially the *ichcapilli*, the quilted cotton tunic two fingers thick, so serviceable as a protection from arrows that the Spanish invaders were glad to adopt it. The archers shot well and with strong bows, though their arrows were generally tipped only with stone or bone; their shields or targets, mostly round, were of ordinary barbaric forms; the spears or javelins had heads of obsidian or bronze, and were sometimes hurled with a spear-thrower or *atlatl*, of which pictures and specimens still exist, showing it to be similar in principle to those used by the Australians and Eskimo. The most characteristic weapon of the Mexicans was the *maquahuitl* or "hand-wood," a club set with two rows of large sharp obsidian flakes, a well-directed blow with which would cut down man or horse. These two last-mentioned weapons have the look of highly developed savage forms, while on the other hand the military organization was in some respects equal to that of an Asiatic nation, with its regular companies commanded each by its captain and provided with its standard. The armies were very large, an expedition often consisting of several divisions, each numbering eight thousand men; but the tactics of the commanders were quite rudimentary, consisting merely of attack by arrows and javelins at a distance, gradually closing into a hand-to-hand fight with clubs and spears, with an occasional feigned retreat to draw the enemy into an ambuscade. Fortification was well understood, as may still be seen in the remains of walled and escarped strongholds on hills and in steep ravines, while lagoon-cities like Mexico had the water approaches defended by fleets of boats and the causeways protected by towers and ditches; even after the town was entered, the pyramid-temples with their surrounding walls were forts capable of stubborn resistance. It was held unrighteous to invade another nation without a solemn embassy to warn their chiefs of the miseries to which they exposed themselves by refusing the submission demanded, and this again was followed by a declaration of war, but in Mexico this degenerated into a ceremonial farce, where tribute was claimed or an Aztec god was offered to be worshipped in order to pick a quarrel as a pretext for an invasion already planned to satisfy the soldiers with lands and plunder, and to meet the priests' incessant demands for more human sacrifices.

Religion. Among the accounts of the Mexican religion are some passages referring to the belief in a supreme deity. The word *teotl*, god, has been thought in some cases to bear this signification, but its meaning is that of deity in general, and it is applied not only to the sun-god but to very inferior gods. It is related that Nezahualcoyotl, the poet-king of Tezcuco, built a nine-storied temple with a starry roof above, in honour of the invisible deity called Tloquenahuaque, "he who is all in himself," or Ipalnemoani, "he by whom we live," who had no image, and was propitiated, not by bloody sacrifices, but by incense and flowers. These divinities, however, seem to have had little or no place in the popular faith, which was occupied by polytheistic gods of the ordinary barbaric type. Tezcatlipoca was held to be the highest of these, and at the festival of all the gods his footsteps were expected to appear in the flour strewn to receive this sign of their coming. He was plainly an ancient deity of the race, for attributes of many kinds are crowded together in him. Between him and Quetzalcoatl, the ancient deity of Cholula, there had been old rivalry. As is *related in the legends, Quetzalcoatl* came into the land to teach men to till the soil, to work metals and to rule a well-ordered state; the two gods played their famous match at the ball-game, and Tezcatlipoca persuaded the weary Quetzalcoatl to drink the magic pulque that sent him roaming to the distant ocean, where he embarked in his boat and disappeared from among men.[1] These deities are not easily analysed, but on the other hand Tonatiuh and Metztli, the sun and moon, stand out distinctly as nature gods, and the traveller still sees in the huge adobe pyramids of Teotihuacan, with their sides oriented to the four quarters, an evidence of the importance of their worship. The war-god Huitzilopochtli was the real head of the Aztec pantheon; his idol remains in Mexico, a huge block of basalt on which is sculptured on the one side his hideous personage, adorned with the humming-bird feathers on the left hand which signify his name, while the not less frightful war-goddess Teoyaomiqui, or "divine war-death," occupies the other side. Centeotl, the goddess of the all-nourishing maize, was patroness of the earth and mother of the gods, while Mictlanteuctli, lord of dead-land, ruled over the departed in the dim under-world. There were numbers of lesser deities, such as Tlazolteotl, goddess of pleasure, worshipped by courtesans, Tezcatzoncatl, god of strong drink, whose garment in grim irony clothed the drunkard's corpse, and Xipe, patron of the goldsmiths. Below these were the nature-spirits of hills and groves, whose shrines were built by the roadside. The temples were called *teocalli* or "god's house," and rivalled in size as they resembled in form the temples of ancient Babylon. They were pyramids on a square or oblong base, rising in successive terraces to a small summit-platform. The great teocalli of Huitzilopochtli in the city of Mexico stood in an immense square, whence radiated the four principal thoroughfares, its courtyard being enclosed by a square, of which the stone wall, called the *coatepantli* or serpent-wall from its sculptured serpents, measured nearly a quarter of a mile on each side. In the centre, the oblong pyramid of rubble cased with hewn stone and cemented 375 × 300 ft. at the base, and rising steeply in five terraces to the height of 86 ft., showed conspicuously to the city the long processions of priests and victims winding along the terraces and up to corner flights of steps. On the paved platform were three-storey tower temples in whose ground-floor stood the stone images and altars, and before that of the war-god the green stone of sacrifice, humped so as to bend upward the body of the victim that the priest might more easily slash open the breast with his obsidian knife, tear out the heart and hold it up before the god, while the captor and his friends were waiting below for the carcase to be tumbled down the steps for them to carry home to be cooked for the feast of victory. Before the shrines reeking with the stench of slaughter the eternal fires were kept burning, and on the platform stood the huge drum, covered with snakes' skin, whose fearful sound was heard for miles. From the terrace could be seen seventy or more other temples within the enclosure, with their images and blazing fires, and the *tzompantli* or "skull-place," where the skulls of victims by tens of thousands were skewered on cross-sticks or built into towers. There also might be seen the flat circular *temalacatl* or "spindle-stone," where captives armed with wooden weapons were allowed the mockery of a gladiatorial fight against well-armed champions. The great pyramid of Cholula with its hemispherical temple of Quetzalcoatl at the top, now an almost shapeless hill surmounted by a church, was about thrice as long and twice as high as the teocalli of Mexico. A large fraction of the Mexican population were set apart as priests or attendants to the services of the gods. The rites performed were such as are found elsewhere—prayer, sacrifice, processions, dances, chants, fasting and other austerities, but there are some peculiarities of detail. Prayers and other formulas have been copied down by Sahagun and other chroniclers, of endless prolixity, but not without occasional touches of pathos. These prayers seem essentially genuine; indeed there was no European model from which they could have been imitated; but at the same time it must be remembered that they come down in Spanish writing, and not untouched by Spanish influence, as in one passage where there is a mention of sheep, an animal unknown to the Mexicans. As to sacrifice, maize and other vegetables were offered, and occasionally rabbits, quails, &c., but, in the absence of cattle, human sacrifice was the chief rite, and cannibalism prevailed at the feasts. Incense was constantly used, especially the *copalli* (copal) well known to us for varnish; little terra-cotta censers are among the commonest of Mexican antiquities. Long and severe religious fasts were customary at special seasons, and drawing blood from the arms, legs and body, by thrusting in aloe-thorns, and passing sharp sticks through the tongue, was an habitual act of devotion recalling the similar practices of devotees in India. The calendar of religious festivals for the Mexican year has been preserved. Each 20-day period had one or more such celebrations. In the month of the "diminishing of waters" the rain gods or Tlalocs were propitiated by a procession of priests with music of flutes and trumpets carrying on plumed litters infants with painted faces, in gay clothing with coloured paper wings, to be sacrificed on the mountains or in a whirlpool in the lake. It is said that the people wept as they passed by; but if so this may have been a customary formality, for the religion of these nations must have quenched all human sympathy. In the next month the god Xipe-totec, already mentioned, had his festival called the "flaying of men" from the human victims being flayed, after their hearts were torn out, for young men to dress in their skins and perform dances and sham fights. The succeeding festival of Camaxtli was marked by a severe fast of the priests, after which stone knives were prepared with which a hole was cut through the tongue of each, and numbers of sticks passed through. For the great festival of Tezcatlipoca, the handsomest and noblest of the captives of the year had been chosen as the incarnate representative of the god, and paraded the streets for public adoration dressed in an embroidered mantle with feathers and garlands on his head and a retinue like a king; for the last month they married him to four girls representing four goddesses; on the last day wives and pages escorted him to the little temple of Tlacochcalco, where he mounted the stairs, breaking an earthenware flute against each step; this was a symbolic farewell to the joys of the world, for as he reached the top he was seized by the priests, his heart torn out and held up to the sun, his head spitted on the tzompantli, and his body eaten as sacred food, the people drawing from his fate the moral lesson that riches and pleasure may turn into poverty and sorrow. The manner of the victim's death in these festivals afforded scope for variety; they dressed them and made them dance in character, threw them into the fire for the fire-god, or crushed them between two balanced stones at the harvest-festival. The ordinary pleasures of festivals were mingled with all this, such as dances in beast-masks, sham fights and children's games, but the type of a religious function was a sickening butchery followed by a cannibal feast.

---

[1] One of the most important sources for the ancient Mexican traditions and myths is the so-called "Codex Chimalpopoca," a manuscript in the Mexican language discovered by the Abbé Brasseur de Bourbourg. It is the interpretation of different mythological and historical Mexican picture-writings, composed by an anonymous author some time after the conquest and copied by Fernando de Alva (Ixtlilxochitl, 1568–1648). It belonged to the priceless collection of Mexican documents brought together in the 18th century by Lorenzo Boturini (see his "Catálogo del Museo historico indiano," appendix of his *Idea de una nueva historia general de la America septentrional*, Madrid, 1746, § viii., No. 13). It is named there *Historia de los reynos de Colhuacan y de Mexico*. Other copies of the same manuscript, made by Leon y Gama, José Pichardo, Aubin and Brasseur, exist in the Paris National Library in the Aubin-Goupil collection. Brasseur died before he could realize his plan to publish the whole MS. in Nahuatl with a translation. Some extracts are to be found in his *Histoire des nations civilisées du Mexique*, and in Leon y Gama, *Dos Piedras* . . . , ed. Bustamente (Mexico, 1832). Larger fragments of the Ixtlilxochitl copy were published in the *Anales del museo nacional de Mexico*, tom. iii., appx. pp. 7–70; but in this edition the Mexican text is very corrupt, and the two Spanish translations are by no means exact. The Paris MSS. and the Ixtlilxochitl copy were carefully collated by Dr Walter Lehmann (see *Zeitschrift für Ethnologie*, 1906, pp. 752–760; *Journal de la Société des Américanistes de Paris, nouv. sér.* vol. iii. No. 2; Dr E. Seler, *Verhandlungen des XVI. Internationalen Amerikanisten-Kongresses*, Vienna, 1909, II., pp. 129–150). The precious Ixtlilxochitl copy was found by Lehmann in the library of the National Museum of México, and arrangements were made for the publication of the whole MS. by him in conjunction with Professor E. Seler. Another very important MS. was discovered by Dr Lehmann, in Guatemala. It is the MS. of Father Francisco Ximenez, *Historia de la Provincia de San Vicente de Chiapa y de Guatemala*, in three big volumes in folio, which contain the famous Spanish translation of the Quiché myths or the "Popol-Vuh." The MS. was bought at the expense of the duke of Loubat, who decided to present it, after the death of Dr Lehmann, to the Royal Library at Berlin.

Picture-writing.

The Mexican priesthood were much concerned with the art of picture-writing, which they used systematically as a means of recording religious festivals and legends, as well as keeping calendars of years and recording the historical events which occurred in them. Facsimiles of several of these interesting documents, with their translations, may be seen in Kingsborough; splendid reproductions of the beautiful Mexican and Mixteco-Zapotecan codices have also been published at the expense of the duke of Loubat and by the "Junta Colombina" (Mexico, 1892). Gods are represented with their appropriate attributes—the fire-god hurling his spear, the moon-goddess with a shell, &c.; the scenes of human life are pictures of warriors fighting with club and spear, men paddling in canoes, women spinning and weaving, &c. An important step towards phonetic writing appears in the picture-names of places and persons. The simplest forms of these depict the objects signified by the name, as where *Chapultepec* or "grasshopper-hill" is represented by a grasshopper on a hill, or a stone with a cactus on it stands for *Tenoch* or "stone-cactus," the founder of *Tenochtitlan*. The system had, however, risen a stage beyond this when objects were drawn to represent, not themselves, but the syllables forming their names, as where a trap, an eagle, a pricker, and a hand are put together not to represent these objects, but in order that the syllables of their names *mo-quauh-zo-ma* should spell the word Moquauhzoma (see Aubin's introduction to Brasseur, *Hist. du Mexique*, i. 68.). The analogy of this to the manner in which the Egyptian hieroglyphs passed into phonetic signs is remarkable, and writing might have been invented anew in Mexico had it not been for the Spanish conquest. The Aztec numerals, which were vigesimal or reckoned by scores, were depicted by dots or circles up to 20, which was represented by a flag, 400 (a score of scores) by a feather, and 8000 (a score of scores of scores) by a purse; but for convenience these symbols might be halved and quartered, so that 534 might be shown by one feather, one quarter of a feather, one flag, one-half of a flag, and four dots. The Mexican calendar depended on the combination of numbers with picture-signs, of which the four principal were the rabbit, reed, flint, house—*tochtli*, *acatl*, *tecpatl*, *calli*. The cycle of 52 years was reckoned by combining these signs in rotation with numbers up to 13, thus: 1 rabbit, 2 reed, 3 flint, 4 house, 5 rabbit, 6 reed, &c. By accident this calendar may be exactly illustrated with a modern pack of cards laid out in rotation of the four suits, as, ace of hearts, 2 of spades, 3 of diamonds, 4 of clubs, 5 of hearts, 6 of spades, &c. In the Mexican ritual calendar of the days of the year, the same method is carried further, the series of twenty day-signs being combined in rotation with numbers up to 13; as this cycle of days only reaches 260, a series of nine other signs are affixed in addition, to make up the 365-day year. It is plain that this rotation of signs served no useful purpose whatever, being less convenient than ordinary counting such as the Mexicans employed in their other calendar already mentioned, where the 20-day periods had each a name like our months, and their days had signs in regular order. Its historical interest depends on its resemblance to the calendar-system of central and eastern Asia, where among Mongols, Tibetans, Chinese, &c., series of signs are thus combined to reckon years, months and days; for instance, the Mongol cycle of 60 years is recorded by the zodiac or series of 12 signs—mouse, bull, tiger, &c., combined in rotation with the five male and female elements—fire, earth, iron, water, wood; as "male-fire-bull" year, &c. This comparison is worked out in Humboldt's *Vues des Cordillères*, as evidence of Mexican civilization being borrowed from Asia. Naturally the Mexican calendar-system lent itself to magic in the same way as the similar zodiac-signs of the Old World, each person's fate being affected by the qualities of the signs he was born under, and the astrologer-priests being called in to advise on every event of life. Of all Mexican festivals the most solemn was that of the *xiuhmolpilli*, or "year-binding," when the 52-year cycle or bundle of years came to an end. It was believed that the destruction of the world, which after the Hindu manner the Mexicans held to have already taken place three or four times, would happen again at the end of a cycle. As the time drew near, the anxious population cleansed their houses and put out all fire, and on the last day after sunset the priests, dressed in the garb of gods, set out in procession for the hill of Huixachtla, there to watch for the approach of the Pleiades to the zenith, which gave the auspicious signal for the lighting of the new fire. The finest of the captives was thrown down and fire kindled on his breast by the wooden drill of the priest; then the victim's heart was torn out, and his body flung on the pile kindled with the new flame. The people watching from their flat housetops all the country round saw with joy the flame on the sacred hill, and hailed it with a thank-offering of drops of blood drawn from their ears with sharp stone-flakes. Swift runners carried burning brands to re-kindle the fires of the land, the sacred fire on the teocalli of the war-god blazed up again, and the people began with feasting and rejoicing the new cycle.

Education.

Mexican education, at any rate that of the upper class, was a systematic discipline much under the control of religion, which here presents itself under a more favourable light. After the birth of a child, the *tonalpouhqui* or "sun-calculator" drew its horoscope from the signs it was born under, and fixed the time for its solemn lustration or baptism, performed by the nurse with appropriate prayers to the gods, when a toy shield and bow were provided if it was a boy, or a toy spindle and distaff if it was a girl, and the child received its name. An interesting picture-writing, to be seen in Kingsborough, shows the details of the boy's and girl's education, from the early time when three small circles over the child show it to be three years old, and a drawing of half a tortilla or corn-cake shows its allowance for each meal; as they grow older the lads are seen beginning to carry burdens, paddle the canoe and fish, while the girls learn to spin and weave, grind maize, and cook—good conduct being enforced by punishments of increasing severity, up to pricking their bodies with aloe-thorns and holding their faces over burning chillies. The schools were extensive buildings attached to the temples, where from an early age boys and girls were taught by the priests to sweep the sanctuaries and keep up the sacred fires, to fast at proper seasons and draw blood for penance, and where they received moral teaching in long and verbose formulas. Those fit for a soldier's life were trained to the use of weapons and sent early to learn the hardships of war; children of craftsmen were usually taught by their fathers to follow their trade; and for the children of nobles there was elaborate instruction in history, picture-writing, astrology, religious doctrines and laws. Marriages depended much, as they do still in the East, on comparison of the horoscopes of the pair to ascertain if their birth-signs were compatible. Old women were employed as go-betweens, and the marriage ceremony was conducted by a priest who after moral exhortations united the young couple by tying their garments together in a knot, after which they walked seven times round the fire, casting incense into it; after the performance of the marriage ceremony, the pair entered together on a four days' fast and penance before the marriage was completed.

Marriages.

Funerals.

The funeral rites of the Mexicans are best seen in the ceremonies at the death of a king. The corpse laid out in state was provided by the priest with a jug of water for his journey, and with bunches of cut papers to pass him safely through each danger of the road—the place where the two mountains strike together, the road guarded by the great snake and the great alligator, the eight deserts and the eight hills; they gave him garments to protect him from the cutting wind, and buried a little dog by his side to carry him across the nine waters. Then the royal body was invested in the mantles of his patron-gods, especially that of the war-god, for Mexican kings were warriors; on his face was placed a mask of turquoise mosaic, and a green chalchihuite-stone as a heart between his lips. In older times the dead king was buried on a throne with his property and dead attendants round him. But after cremation came in a mourning procession of servants and chiefs carrying the body to the funeral pyre to be burnt by the demon-dressed priests, after which the crowd of wives and slaves were exhorted to serve their lord faithfully in the next world, were sacrificed and their bodies burnt. Common people would not thus be provided with a ghostly retinue, but their simpler funeral ceremonies were as far as they went similar to those of their monarch.

The staple food of the Mexicans before the conquest has continued with comparatively little change among the native race, and has even been adopted by those of European blood. **Agriculture and food.** Maize or Indian corn was cultivated on patches of ground where, as in the Hindu *jūm*, the trees and bushes were burnt and the seed planted in the soil manured by the ashes. A sharp-pointed planting stick, a wooden shovel, and a bronze-bladed hoe called a *coatl* were the simple implements. The Mexicans understood digging channels for irrigation, especially for the cultivation of the *cacahuatl*, from which they taught the Europeans to prepare the beverage *chocollatl*; these native names passed into English as the words cacao, or coco and chocolate. Other vegetables adopted from Mexico are the tomato (*tomatl*) and the *chilli*, used as flavouring to native dishes. The maize was ground with a stone roller on the grinding stone or *metlatl*, still known over Spanish America as the *metate*, and the meal baked into thin oval cakes called by Aztecs *tlaxcalli*, and by Spaniards *tortilla*, which resemble the *chapati* of India and the oatcake of Scotland. The Mexicans were also skilful makers of earthen pots, in which were cooked the native beans called by the Spanish *frijoles*, and the various savoury stews still in vogue. The juice extracted by tapping the great aloe before flowering was fermented into an intoxicating drink about the strength of beer, *octli*, by the Spaniards called *pulque*. Tobacco, smoked in leaves or cane-pipes or taken as snuff, was in use, especially at feasts. **Clothing and Ornaments.** In old times Mexican clothing was of skins of woven aloe and palm fibre, but at the time of the conquest cotton was largely cultivated in the hot lands, spun with a spindle, and woven in a rudimentary loom without a shuttle into the mantles and breech-cloths of the men and the chemises and skirts of the women, garments often of fine texture and embroidered in colours. Ornaments of gold and silver, and jewels of polished quartz and green chalchihuite were worn—not only the ears and nose but the lips being pierced for ornaments. **Metal-work.** The artificers in gold and silver melted the metals by means of a reed-blowpipe and cast them solid or hollow, and were also skilled in hammered work and chasing, as some fine specimens remain to show, though the famous animals modelled with gold and silver, fur, feathers and scales have disappeared. Iron was not known, but copper and tin ores were mined, and the metals combined into bronze of much the same alloy as in the Old World, of which hatchet blades and other instruments were made, though their use had not superseded that of obsidian and other sharp stone flakes for cutting, shaving, &c. Metals had passed into a currency for trading purposes, especially quills of gold-dust and T-shaped pieces of copper, while coco-beans furnished small change. The vast size of the market-squares with their surrounding porticos, and the importance of the caravans of merchants who traded with other nations, show that mercantile had risen into some proportion to military interests. Nor was the wealth and luxury of Mexico and surrounding regions without a corresponding development of art. **Art and Pastime.** The stone sculptures such as that remaining of Xochicalco, which is figured by Humboldt, as well as the ornamented woodwork, feather-mats, and vases, are not without artistic merit. The often-cited poems attributed to Nezahualcoyotl may not be quite genuine, but at any rate poetry had risen above the barbaric level, while the mention of ballads among the people, court odes, and the chants of temple choirs would indicate a vocal cultivation above that of the instrumental music of drums and horns, pipes and whistles, the latter often of pottery. Solemn and gay dances were frequent, and a sport called the bird-dance excited the admiration of foreigners for the skill and daring with which groups of performers dressed as birds let themselves down by ropes wound round the top of a high mast, so as to fly whirled in circles far above the ground. The ball-game of the Mexicans, called *tlachtli*, was, like tennis, the pastime of princes and nobles; special courts were built for it, and the ball of india-rubber (perhaps the first object in which Europeans became acquainted with this valuable material) might not be touched by the hands, but was driven against the walls by blows of the knee or elbow, shoulder or buttock. The favourite game of *patolli* has been already mentioned for its similarity to the *pachisi* of modern India.

The accounts given by Spanish writers of the Central Americans in their state after the Spanish conquest are very scanty in comparison with the voluminous descriptions of Aztec life. They bring out perfectly, however, the fact of close connexion between the two civilizations. **Central-American Culture.** Some Central-American peoples were actually Mexican in their language and culture, especially the Pipils and a large part of the population of Nicaragua. The investigations made by Dr Walter Lehmann in Central America (1907–1909), prove that these Mexican elements were extended through Guatemala, Salvador, a small part of Nicaragua (the territory of the Nicaraos) and on several places in the peninsula of Nicoya (Costa Rica) amongst the autochthonous Chorotega or Mangue. It is an error of the Spanish authorities to pretend that the Pipil civilization in Guatemala and Salvador is not older than the time of King Ahuitzotl (*c.* 1482–1486). The language spoken by the Pipils of Salvador (Balsam Coast) is a very old dialect of the Mexican language of the highland of Mexico. It has preserved in the conjugation and in the formation of the plural older forms than the classical Nahuatl itself. The separation of the Pipils from the chief tribes of the Nahuatl branch happened centuries before the conquest, and they developed a singular and characteristic civilization, which can be seen in the wonderful stone-reliefs and sculptures of Sta Lucia de Cozumalhuapa on the Pacific coast of Guatemala.

Dr Lehmann's archaeological and linguistic researches, especially in Salvador and Nicaragua, also enabled him to prove another very important fact, viz. that these Pipils, who may be descendants from the peoples of the Mexican Plateau, migrated into territories previously occupied by an older race of Mayan origin. The archaeological and linguistic evidence proves also that a great part of Salvador and Honduras was once occupied by peoples of the Maya race—Pokomam, Chorti and perhaps other unknown tribes. They left typical Mayan ruins in Honduras (Tenampua) and in Salvador (Opico near Tehuacan, Quelepa near San Miguel), which seem, however, to be destitute of Mayan hieroglyphic inscriptions. The easternmost limit of prehistoric Mayan civilization, on the Pacific coast of Central America, is Fonseca Bay, with the island of Zacate Grande.

It is noteworthy that archaeological objects of the type characteristic of northern Honduras (Ulloa Valley) have been found on the Pacific coast of Salvador. A strange stone sculpture of the so-called Chac-Mol type, known before only from the country of the Tarascs, from Tlaxcala and Chichen Itza, was discovered in Salvador (Ahuachapan).

In the nearly unexplored central part of Nicaragua Dr Lehmann found fragments of painted polychrome clay pottery similar to objects known from the Ulloa Valley (Honduras) amongst other ceramic pieces which seem to have been left by the ancestors of the Sumo Indians, now extinct in that territory. It is possible that these remains of Mayan pottery came into central Nicaragua as articles of commerce.

It is significant that Mayan civilization cannot be traced in any other part of Nicaragua or Costa Rica.

The above-mentioned prehistoric Mayan peoples lived in contact with "barbarous" nations and with another little-known civilized race. The barbarians belonged to the great family of the Sumo-Misquito Indians, the civilized race was that of the Chorotega or Mangue (Dirian, Orotiñan, &c.). The Sumo-Misquito Indians occupied the Atlantic coast and the interior of Nicaragua and Honduras, where they still live in small tribes; a dialect of the hitherto unknown Sumo languages is the Matagalpan, now extinct in Nicaragua, and nearly identical with the Matagalpan is the language spoken by the Indians of Cacaopera in Salvador (Ultra-Lempa territory). There is no doubt that, at the time of the Pipil invasion, tribes of the Sumo-Misquito family were the immediate neighbours of the Pipils towards the east and north. This fact is proved by the names of some places in Salvador, *e.g.* Santiago Nonohualco, San Juan Nonohualco and San Pedro Nonohualco. The word *Nonohualco* signifies in the Mexican language a place where a language changes, where another idiom begins. To the east of the three places whose names are compounded with "Nonohualco," must have dwelt, in the time of the Pipil Indians, the Nonoualca, called also by Mexican tribes Chontales or Popoloca. The western neighbours of the Sumo Indians were and are (though few still survive) the Lenca Indians, who formerly occupied large parts of Honduras. A linguistic relationship can be established between all the Indian languages spoken on the Atlantic coast and in the interior of Nicaragua and Honduras. Several tribes, such as the Paya (or Poya) and the Jicaques, form together with the Lenca, Sumo (Matagalpa, Tauakhca and Ulua) and Misquito one great family.

The position of the isolated Xinca (or Sinca) Indians, regarded from this point of view, becomes very interesting. There are scientific reasons to believe that the Xinca also belong to the same great family as the Lenca, Jicaques, Paya, Misquito-Sumo. It may be possible either that these tribes are the autochthonous inhabitants who dwelt in Guatemala, Salvador, Honduras and Nicaragua before the immigration of the prehistoric Maya peoples; or else that they invaded this region after it had been deserted by a prehistoric oriental branch of the Maya family.

The Chorotega race had its centre in Nicaragua (Pacific coast) and at one time extended thence as far as Guanacaste (Costa Rica); at another time it extended as far as Honduras (actual department of Choluteca) and into eastern Salvador as far as the state of Chiapas in Mexico, where the Chorotega penetrated amongst the Mixe. The Chorotega or Mangue language, so closely affiliated to the Chiapanec, is now extinct, but its former extension is to be recognized by many Indian local names. It seems that there was formerly a mutual interpenetration between Lenca, Sumo and Chorotega tribes. The territories of all these tribes can be, more or less exactly, calculated by the existence of Indian local names. The Misquito country is characterized by names terminating in *laya*, water, or *auala*, river; the Sumo and Ulua country by names in *uas*, water; the Matagalpan by names in *li*, water; the Lenca by names in *tique*, *lique*, *isque and* (*ai*) *quin*. Such Lenca names occur on the north-eastern boundary of the Ultra-Lempa country of Salvador. It is strange that there is not a single place-name in Salvador either of Mayan origin, or, as it seems, of Chorotegan origin. Probably the Mexican elements superseded the Maya so completely that there remained no trace of the Maya except archaeological objects; it is to be supposed that the Lenca and Sumo tribes superseded the Chorotega in Salvador. If we can be sure—and the linguistic evidence admits of no doubt—that the Chorotega had their centre in Nicaragua and thence extended north-westwards, it may be hoped that Chorotegan remains will be found in the vast territory occupied for many centuries by the Maya peoples in the Pacific part of Guatemala. These remains would, of course, be archaeological or place-names.

How closely related some of the Central-American nations were in institutions to the Mexicans appears, not only in their using the same peculiar weapons, but in the similarity of their religious rites; the connexion is evident in such points as the ceremony of marriage by tying together the garments of the couple, or in holding an offender's face over burning chillies as a punishment; the native legends of Central America make mention of the royal bali-play, which was the same as the Mexican game of tlachtli already mentioned. At the same time many of the Central-American customs differed from the Mexican; thus in Yucatán we find the custom of the youths sleeping in a great bachelor's house, an arrangement common in various parts of the world, but not in Mexico; the same remark applies to the Maya exogamous law of a man not taking a wife of his own family name (see Diego de Landa, *Relacion de Yucatan*, ed. Brasseur de Bourbourg, p. 140), which does not correspond with Mexican custom. We have the means of comparing the personal appearance of the Mexicans and Central Americans by their portraits on early sculptures, vases, &c.; and, though there does not appear any clear distinction of race-type, the extraordinary back-sloping foreheads of such figures as those of the bas-reliefs of Palenque prove that the custom of flattening the skull in infancy prevailed in Central America to an extent quite beyond any such habit in Mexico. The notion that the ruined cities now buried in the Central-American forests were of great antiquity and the work of extinct nations has no solid evidence; some of them may have been already abandoned before the conquest, but others were inhabited by the ancestors of the Indians who now build their mean huts and till their patches of maize round the relics of the grander life of their ancestors. In comparing these ruins in Yucatán, Chiapas, Guatemala and Honduras, it is evident that, though they are the work of two or more nations highly distinct in language, yet these nations had a common system of pictorial or written characters. One specimen of a Central-American inscription may give a general idea of them all, whether it be from the sculptured façade of a temple sketched by Catherwood, or from the painted deerskin called the Dresden Codex (reproduced in Kingsborough), or from the chapter of Diego de Landa where he professes to explain and translate the characters themselves. These consist of combinations of faces, circles, lines, &c., arranged in compartments in so complex a manner that hardly two are found alike. How they conveyed their meaning, how far they pictorially represented ideas or spelt words in the different languages of the country, is a question not yet answered in a complete way; Landa's description (p. 320) gives a table of a number of their elements as phonetically representing letters or syllables, but, though there may be a partial truth in his rules, they are insufficient or too erroneous to serve for any general decipherment. One point as to the Central-American characters is clear, that part of them are calendar-signs recording dates. From the accounts given by Landa and other writers it is plain that the Central-American calendar, reckoning the year in twenty-eight periods of thirteen days, was the same in its principle of combining signs as that of Mexico. The four leading Maya signs called *kan*, *muluc*, *ix*, *cauac* corresponded in their position to the four Aztec signs rabbit, reed, flint, house, but the meanings of the Maya signs are, unlike the Aztec, very obscure. A remarkable feature of the Central-American ruins is the frequency of truncated pyramids built of hewn stone, with flights of steps up to the temple built on the platform at top. The resemblance of these structures to the old descriptions and pictures of the Mexican teocallis is so striking that this name is habitually given to them. The teocallis built by the Nahua or Mexican nations have been mostly destroyed, but two remain at Huatusco and Tusapan (figured in Bancroft, iv. 443, 456), which bear a strong resemblance to those of Palenque. On the whole it is not too much to say that, in spite of differences in style, the best means of judging what the temples and palaces of Mexico were like is to be gained from the actual ruins in Central America. On the other hand, there are features in Central-American architecture which scarcely appear in Mexican. Thus at Uxmal there stands on a terraced mound the long narrow building known as the governor's house (Casa del Gobernador), 322 ft. long, 39 ft. wide, 26 ft. high, built of rubble stone and mortar faced with square blocks of stone, the interior of the chambers rising into a sloping roof formed by courses of stonework gradually overlapping in a "false arch." The same construction is seen in the buildings forming the sides of a quadrangle and bearing the equally imaginary name of the nunnery (Casa de Monjas); the resemblance of the interior of one of its apartments to an Etruscan tomb has often been noticed (see Fergusson, *History of Architecture*, vol. i; Viollet-le-Duc, in Charnay).

The explorations made by Dr Lehmann in 1909 in the famous ruins of Teotihuacan, near Mexico city throw new light upon certain chronological problems. Like the excavations made by Dr Max Uhle in Peru, they tend to determine the relative antiquity of the different periods of the ancient civilization. They also show that these various culture-periods followed one another among the Mexicans in much the same sequence as among the Peruvians. At a considerable depth below the foundations of a temple-palace at Teotihuacan, Dr Lehmann discovered certain ceramic fragments of a type quite different from any hitherto classed as Mexican. These are painted on a fine stucco in beautiful colours (notably a kind of turquoise-green) and represent archaic forms of flowers and butterflies. The relation between the wall paintings of Teotihuacan and ornaments at Chichen Itza, as also the existence of sculptured stone yokes in Teotihuacan, in the country of the Totonacs, in Guatemala and in Salvador, furnish important material for the investigation of the obscure problems of the Toltecs and Olmecs, and of the extension of Maya peoples on the Atlantic coast of the Mexican Gulf from Campeche as far as Tabasco and Vera Cruz.

Attempts to trace the architecture of Central America directly from Old-World types have not been successful, while on the other hand its decoration shows proof of original invention, especially in the imitations of woodwork which passed into sculptured ornament when the material became stone instead of wood. Thus the architectural remains, though they fail to solve the problem of the culture of the nations round the Gulf of Mexico, throw much light on it when their evidence is added to that of religion and customs. At any rate two things seem probable—first, that the civilizations of Mexico and Central America were pervaded by a common influence in religion, art, and custom; second, that this common element shows traces of the importation of Asiatic ideas into America.

BIBLIOGRAPHY.—The most illuminating and fundamental work on Mexican archaeology is the *Gesammelte Abhandlungen*, of Eduard Seler (vol. i. Berlin, 1902; vol. ii., 1904). For the earliest descriptions of the ancient cities of Mexico the writings of Cogolludo, Landa, Antonio del Rio, Sahagun, Torquemada and others are of the greatest value. The account by Antonio de Leon y Gama, *Descripcion historica y cronologica de las dos piedras que . . . se hallaron en la plaza principal de Mexico el año de 1790* (Mexico, 1792; 2nd ed. by C. M. de Mustamentel), may be specially mentioned. Much of this material is to be found in Lord Kingsborough's monumental work in 9 vols., seq., on the *Antiquities of Mexico* (London, 1831–1848). Alexander von Humboldt's *Vues des Cordillères et monuments des peuples indigènes de l'Amerique* was published in Paris in 1816. At the beginning of the 19th century the colonial government undertook a comprehensive exploration of the best known groups of ruins and three expeditions were made in 1805–1808 under the direction of Captain Guillaume Dupaix, accompanied by Luciano Castañeda as artist. The reports were not published, however, until Kingsborough included them in his work, though some of the drawings appeared in other works. In many respects these reports are the best of the early accounts. Another early explorer was the French artist Frédéric de Waldeck, who published *Voyage pittoresque et archéologique dans la province d'Yucatan* (Paris, 1838), and whose collection of drawings appeared in 1866, with the descriptive text by Brasseur de Bourbourg, under the title *Monuments anciens du Mexique*. Among other and later works, including some who have devoted themselves more especially to Maya inscriptions, are: Arnold and Frost, *The American Egypt* (London, 1909); H. H. Bancroft, *The Native Races of the Pacific States* (5 vols., New York, 1874–1876, vol. iv. is devoted to "Antiquities"); A. F. Bandelier, *Report on an Archaeological Tour in Mexico, 1881* (Archaeol. Inst. of America, papers, Am. Ser. II.); Leopoldo Batres, *Cuadro arqueólógico y etnográfico de la Republica Mexicana* (Mexico, n.d.); W. W. Blake, *Catalogue of the Historical and Archaeological Collections of the National Museum of Mexico* (Mexico, 1884); Eug. Boban, *Cuadro arqueológico y etnográfico de la Republica Mexicana* (Paris, 1885); Daniel G. Brinton, *The American Race* (New York, 1891) and *Ancient Phonetic Alphabets of Yucatan*; Desiré Charnay, *The Ancient Cities of the New World* (Transl. New York, 1887); Charnay and Viollet-le-Duc, *Cités et ruines américaines* (Paris, 1863); Alfredo Chavero (ed.) *Antiguedades mexicanas* (Mexico, 1892); Dupaix, *Antiquités mexicaines* (Paris, 1834–1836); E. Förstemann (Numerous articles in *Globus* and other German publications, 1893–1897, on Maya inscriptions); E. T. Hamy, *Decades americanae* (Paris, 1888, 1898, 1902); Wm. H. Holmes, *Archaeological Studies among the*

Ancient Cities of Mexico (Parts I. and II. Field Columbian Museum, Chicago, 1895–1897); W. Lehmann, *Ergebnisse und Aufgaben der mexikanischen Forschung* (*Archiv. für Anthropologie, neue Folge*, iii., 2; 1907), Eng. trans.: *Methods and Results in Mexican Research*, by Seymour de Ricci (Paris, 1909); Theobert Maler, *Neue Entdeckung von Ruinen-Städten in Mittel-Amerika* (*Globus*, lxx. 149–150, Braunschweig, 1896), and also contributions to American archaeological publications; A. P. Maudslay, *Biologia Centrali-Americana-Archaeology* (London, 1897); J. F. A. Nadaillac, *Prehistoric America* (New York, 1895); Zelia Nuttall, *The Fundamental Principles of the Old and New World Civilizations* (Arch. and Ethn. Papers, Peabody Museum, Cambridge, 1901); Antonio Penafiel, *Monumentos del arte mexicano antiguo* (1 vol. text, 2 vols. plates; Berlin, 1890); Carl Sapper, *Das nördliche Mittel-Amerika* (Braunschweig, 1897); Caecilie Saler, *Auf alten Wegen in Mexico und Guatemala* (Berlin, 1900); Eduard K. Seler, "Der Charakter der aztekischen und Maya-Handschriften" (*Zeitschrift für Ethnologie*, Berlin, 1888), and other papers in various German publications; John L. Stephens (F. Catherwood, artist), *Travels in Central America* (2 vols., New York, 1841), and *Incidents of Travel in Yucatan* (2 vols., New York, 1843).

(E. B. T.; W. L.*)

II.—Colonial Period. 1520–1821.

The conquest of Mexico by the Spanish forces under Hernando Cortes (*q.v.*) in 1520, and the death of the last Aztec emperor, Guatemozin, introduced what is known as the colonial period of Mexican history, which lasted down to the enforced resignation of the last viceroy, O'Donoju, in 1821. During these three centuries, after a brief but most unsatisfactory experience of government by audiencias (1521–1535), sixty-four viceroys ruled over New Spain. Of these a few were ecclesiastics: two had two terms of office; only two or three were of native birth, and their previous official life had always been passed in other parts of the Spanish dominions.

New Spain: Extent.

New Spain was one of four great viceroyalties, the other three being New Granada, Buenos Aires and Peru. Its viceroy ruled over districts differing in status and with overlapping and conflicting authorities, some of these being appointed directly by the king of Spain, and responsible to him. New Spain in its widest meaning includes the audiencias or judicial districts of Manila, San Domingo and Guatemala, and the viceroy had some sort of authority over them: but in its narrower meaning it comprised the audiencia district of Mexico and the subordinate audiencia district of Guadalajara, which together extended from Chiapas and Guatemala to beyond the eastern boundary of the modern state of Texas and northwards, eventually, to Vancouver's Island. In the course of the 18th century this came to consist of the following divisions: (1) the kingdom of Mexico, which included the peninsula of Yucatán but not the present state of Chiapas or a part of Tabasco, these belonging to Guatemala. Approximately its south border ran from a point slightly east of Tehuantepec to the bay of Honduras, and its north limit was that of the modern states of Michoacan and Guanajuato, then cutting across San Luis Potosí to a point just above Tampico. (2) The kingdom of New Galicia, including the present states of Zacatecas, Jalisco and part of San Luis Potosí. (3) The Nuevo Regno de Leon (the present state of that name). (4) The Provincias Internas, *i.e.* "interior" regarded from the capital, viz. Nuevo Santander (Tamaulipas, and Texas to the bay of Corpus Christi, founded 1749), the several provinces of Nuevo Biscaya or Chihuahua, Durango, Sonora with Sinaloa, Coahuila, Texas (from Corpus Christi Bay to the mouth of the Mermenton in the present state of Louisiana), and the two Californias.

Government and Organization.

The audiencia councils also advised the viceroy in matters of administration; and, as with other officials, his career was subject at its close to a formal examination by a commission—a process known as "taking his residencia." Local government till 1786 was largely in the hands of *alcaldes majores* and *corregidores*, the latter established in 1531 to look after the Indians, and both appointed by purchase. Towns, which were to some extent founded after the conquest as centres of civilization for the Indians, were governed by civic officials appointed in the first instance by the governor of the province, but subsequently as a rule purchasing their posts.

The Church and the People.

The church rapidly supplemented the work of the conquerors. The first Franciscan mission arrived in 1524; other orders followed. The announcement of the apparition of the Virgin to an Indian near Mexico City provided a place of pilgrimage and a patroness in Our Lady of Guadalupe; and the friars ingeniously used the hieroglyphic writing for instruction in Christian doctrine, and taught the natives trades, for which they showed much aptitude. The university of Mexico was founded in 1553. The Jesuits established themselves in 1572, devoting themselves actively to the education both of whites and of natives, and were a powerful factor in the exploring and civilizing of the northern districts. The Inquisition was introduced in 1571. With the natives south of the latitude of Tampico there was little trouble after the Mixton War (in Guadalajara) in 1540–1562, save for occasional risings in Yucatán, Tehuantepec, and in 1711 in the Nayarit mountain region west of Zacatecas, and Tamaulipas was conquered in 1748; but the wild Indians of Sonora and New Mexico gave constant trouble to the missions and outlying settlers. There were occasionally riots due to scarcity of corn (notably in Mexico itself in 1692). As in other Spanish possessions, Indian labour was replaced or supplemented by that of negro slaves, but these were almost wholly confined to the coast regions of Vera Cruz and Acapulco, and early in the 19th century there were only some 10,000 in all.

Races and Castes.

As the Spanish conquerors brought few women, there was much mixture of races. Among the pure whites—who were practically all of Spanish extraction—there were two well-defined classes, the Gachupines or chapetones, Spaniards born in Europe, said to be so named in allusion to their spurs, from Aztec words meaning "prickers with the foot," and the native-born or creoles: the former, though a small minority, had almost all the higher positions both in the public services and in commerce. Besides these there were five well-defined *castas*: mestizoes (Indian and white); mulattoes (negro and white); Zambos (negro and Indian), who were regarded as specially vicious and dangerous; native Indians and negroes. But there were about a dozen intermediate "named varieties," of which the *salto-atras* (tending away from white) and *tente en l'aire* (tending towards white) may be mentioned; and many of the last named eventually passed into the Creole class, sometimes by the decree of a court. The fact that the trade route to Manila passed through Vera Cruz, Mexico City and Acapulco entailed the settlement also of a few Chinese and Malays, chiefly on the Pacific coast.

Position of the Natives.

The natives were subject to tribute and kept in perpetual tutelage: divided at the conquest, with the land, as serfs of the conquerors, in *repartimientos* or *encomiendas*, they were gradually freed at an early date from their serfage, and allowed to sell their labour as they pleased; they were, however, to a great extent kept in villages or settlements, compelled to cultivate land which they held for their life only, and strictly controlled by the friars or the priests. Their numbers were several times seriously reduced by the *matlazhuatl*, apparently analogous to yellow fever, but not attacking the whites, and unknown before the conquest. The negroes were allowed to buy their freedom gradually at rates fixed by the judicial authorities, and slavery seems never to have taken much hold except in the coast region.

Leading Events: 1535-1822.

Of the events of this period only a bare outline can here be given. The term of office of the first viceroy, Antonio de Mendoza, was marked by the Mixton War, by an attempt to suppress the encomienda system, and by a violent epidemic among the natives. Under his successor, Velasco, the measures taken for the relief of the natives provoked the landowners to a conspiracy (repressed with great severity) to set up Cortes' son as king of New Spain. In 1568 the island of Sacrificios, near Vera Cruz, was seized by John Hawkins (*q.v.*), who was surprised by the Spanish fleet accompanying the new viceroy, de Almansa, and escaped with Sir Francis Drake (*q.v.*), but without the remaining ships of his squadron. In 1572 and 1578, however, Drake took abundant vengeance, and in 1587 Cavendish captured the Manila galleon—a success repeated in the next century.

The Drainage of the Capital.

For the next sixty years an urgent question was the prevention of floods in the capital. Situated on the lowest of four lakes, whose waters had only one small outlet from the valley, it was only 4 ft. above the level of the lowest, and was flooded on an average once in every twenty-five years. It had been protected under the native kings by a system of dikes, which were added to under the earlier viceroys, but serious inundations in 1553 and 1580 flooded the city, and the latter suggested the relief of the highest lake, that of Zumpango, by a tunnel carrying its chief affluent into a tributary of the Panuco, and so to the Atlantic. This, however, was not then undertaken, and when mooted again in 1603 was opposed as certain to involve a heavy sacrifice of Indian life. Another inundation, in 1604, suggested the transfer of the city to Tacubaya, but the landowners opposing and the city being again inundated in 1607, the Nochistongo tunnel was begun under the auspices of a Jesuit, Enrico Martinez, and roughly completed in eleven months. It passed under a depression in the mountains of the extreme north of the valley. Humboldt states that it was 6600 metres long, 3½ wide and 4 high. But it did nothing for the southern lakes, so that a further system of dikes was recommended in preference, in 1614, by the Dutch engineer Adrian Boot; it was inadequate for its work and, not being lined with masonry, it was liable to be choked by falls. Repairs were suspended in 1623, and a further inundation, with great losses of life, occurred from 1629 to 1634. The removal of the city was again mooted and, though sanctioned by the king of Spain, successfully opposed by the landowners. Another flood occurred in 1645. After a disastrous attempt to enlarge the tunnel in 1675, it was eventually converted into an open cutting, but the work was not finished till 1789, and the bottom was then 29 ft. 6 in. above the level of the lowest lake. The drainage was only satisfactorily accomplished at the end of the 19th century (see below).

Church and State.

A negro revolt in the Vera Cruz region (1609) and an Indian rebellion in Sinaloa and Durango may be mentioned among the events of the earlier part of the 17th century. The regular and secular clergy had early come into conflict, particularly over the tithe and the control of the Indians; and in 1621, the marquis de Gelves, an energetic reformer, who as viceroy favoured the appointment of the regulars to deal with the natives, came into conflict with Archbishop Serna of Mexico, who placed the city under interdict, excommunicated the viceroy and constrained him to hide from the mob. Some years later the bishop of Puebla, Juan de Palafox y Mendoza, transferred many native congregations from the friars to secular priests, and subsequently, in 1647, came into conflict with the Jesuits, whom he excommunicated, but who eventually triumphed with the aid of the Dominicans and the archbishop. The power of the church may be judged from the petition of the Ayuntamiento of Mexico to Philip IV. (1644) to stop the foundation of religious houses, which held half the property in the country, to suspend ordinations because there were 6000 unemployed priests, and to suppress feast days because there were at least two per week.

Buccaneer Raids.

To check the Dutch and British corsairs the Barlovento ("windward") squadron had been set up in 1635; but the British capture of Jamaica (1655) aggravated the danger to the Spanish convoys. During the rest of the century the ports of Yucatán and Central America were frequently raided, and in 1682 Tampico suffered a like disaster; in May 1683 Vera Cruz itself was captured through stratagem by two buccaneers, Van Horn and Laurent, who plundered the town for ten days, committed shocking outrages, and escaped as the Spanish fleet arrived. In 1685–86 the Pacific coast was ravaged by Dampier and Swan, and in 1709 Woodes Rogers, with Dampier as pilot, captured the Manila treasure galleon, a feat repeated by Anson in 1743. But the European wars of the 18th century had little effect on Mexico, save that the privileges of trade given to Great Britain by the treaty of Utrecht facilitated smuggling. In the first half of the 18th century we may note the appearance, intermittently at first, of the first Mexican periodical—the *Gaceta de Mexico*—in 1722, a severe epidemic of yellow fever in 1736, and the establishment about 1750 of a standing army with a nucleus of Walloons and Swiss, negroes and Indians being excluded and the half-breeds admitted under restrictions. But the great event of the 18th century was the expulsion of the Jesuits from Mexico, as from the other Spanish dominions, in 1767, under orders from Charles III. They were arrested *en masse* on the night of the 26th of June; their goods were sequestrated, and they themselves deported to Havana, then to Cadiz, Genoa, and eventually Corsica. They had done much to civilize the natives and to educate the whites, and their expulsion, which was greatly resented by the Creoles, probably tended to increase the popular discontent and prepare for the overthrow of Spanish rule.

Centralized Government.

In 1769 Don José de Galvez was sent out as special commissioner to devise reforms, with powers independent of the then viceroy, but without much immediate result. It was, however, a consequence of his work that in 1786 the provinces and kingdoms were replaced by twelve intendencias (Guadalajara, Zacatecas, Durango, Sonora, Puebla, Vera Cruz, Merida, Oaxaca, Valladolid, Guanajato, San Luis Potosí, Mexico), whose governors and minor officials were directly dependent on the viceroy, the former alcaldes, mayores and corregidores, who were very corrupt, being abolished. Possibly it is from this reform that we may date the antithesis of Federals and Centralists, which is so conspicuous in the history of republican Mexico. Among the later viceroys the Conde de Revillagigedo (1789–1794) deserves mention as a progressive ruler who developed commerce and improved administration, and took the first, but very imperfect, census, on which Humboldt based his estimate of the population in 1803 at 5,840,000.

Beginnings of Severance.

The European wars of the French revolutionary period interfered with the traffic with Spain, and so relaxed the bonds of a commercial system which hampered the manufactures of Mexico and drained away its wealth. Already in 1783 the Conde de Aranda had suggested to the Spanish king the scheme of setting up three Spanish-American kingdoms bound to Spain by perpetual treaties of alliance and reciprocity and by frequent royal intermarriages, and with the king of Spain as overlord. The plan was devised as a means of rivalling Anglo-Saxon supremacy, but was rejected through fear of the mixed races predominating over the whites. A similar fear helped to keep down the tendencies inspired by French revolutionary literature, though plots occurred against the viceroy Branciforte in 1798 and 1799. But the real causes of the revolution were local. The chief was the Creole jealousy of the Spanish immigrants. There was oppressive taxation, restriction on commerce and manufacture in the interest of Spain, even vineyards having been prohibited; and the courts were very corrupt. But to these grievances was added in 1804 the sequestration, to provide for Spain's needs, of the benevolent funds (*obras pias*) in Mexico, amounting to about $45,000,000, and nearly all invested on mortgage. The mortgages were called in: forced sales were necessary, the mortgagers were frequently ruined, and less than a fourth of the total was realized. Other confiscations and exactions followed; and when the rule of Fernando VII. was succeeded by that of Joseph Bonaparte, the municipality of Mexico invited Iturrigaray, the viceroy, to declare the country independent. He proposed the convocation of a national congress, but was overthrown by a conspiracy of Spaniards under one Yermo, who feared that they would lose their privileged position through severance from Spain. The two next viceroys were incompetent; further demands from the Spanish authorities in revolt against Joseph Bonaparte increased the disaffection, which was not allayed by the grant of representation in the Spanish Cortes to the colonies; and, on the demands being repeated by a third viceroy, Venegas, Creole conspiracies arose in Querétaro and Guanajato. Their discovery in 1810 was followed by the outbreak of the revolution. Hidalgo, a parish priest, and Allende, a captain of cavalry, with forces consisting largely of Indians, captured a stronghold at Guanajato and even threatened the capital; but the revolutionists were defeated in 1811 at Calderon, and the leaders executed. Another priest, however, named Morelos, continued the movement, and, despite defeat in the terrible siege of Cuatla (now Morelos) on the 2nd of May 1812, raised the south, so that in the next year his forces overran most of the kingdom of Mexico and held its southern parts, and he was able to convoke a congress and issue a constitution. But he also was captured, and executed at Mexico City in 1815. Though revolutionary movements still continued, by 1817 only one leader, Vincente Guerrero, was left in the field. But in March 1820 the Spanish constitution, repudiated by King Fernando VII. soon after his restoration, was restored after a military rising in Spain. It was promulgated in Mexico, and the ecclesiastics and Spaniards, fearing that a Liberal Spanish government would force on them disendowment, toleration and other changes, induced Augustin de Iturbide, who had already been conspicuous in suppressing the risings, to take the field in order to effect what may be called a reactionary revolution.

III.—Independent Mexico.

General Characteristics.

Thenceforward, till the second election of Porfirio Diaz to the presidency in 1884, the history of Mexico is one of almost continuous warfare, in which Maximilian's empire is a mere episode. The conflicts, which may at first sight seem to be merely between rival generals, are seen upon closer examination to be mainly (1) between the privileged classes, *i.e.* the church and (at times) the army, and the mass of the other civilized population; (2) between Centralists and Federalists, the former being identical with the army, the church and the supporters of despotism, while the latter represent the desire for republicanism and local self-government. Similar conflicts are exhibited, though less continuously, by most of the other Spanish-American states. On both sides in Mexico there was an element consisting of honest doctrinaires; but rival military leaders exploited the struggles in their own interest, sometimes taking each side successively; and the instability was intensified by the extreme poverty of the peasantry, which made the soldiery reluctant to return to civil life, by the absence of a regular middle class, and by the concentration of wealth in a few hands, so that a revolutionary chief was generally sure both of money and of men. But after 1884 under the rule of Diaz, the Federal system continued in name, but it concealed in fact, with great benefit to the nation, a highly centralized administration, very intelligent, and on the whole both popular and successful—a modern form of rational despotism.

General Iturbide becomes Emperor, 1822-1823.

Iturbide eventually combined with Guerrero, and proclaimed the "Plan of Iguala," which laid down, as the bases of the new state, the maintenance of the Roman Catholic religion and the privileges of the clergy, the establishment of a limited monarchy, and equality of rights for Spaniards and native-born Mexicans. Iturbide sought the co-operation of the viceroy Apodaca, who, however, refused; but he was presently superseded by General O'Donojú, who, being unable to get beyond Vera Cruz, recognized the independence of Mexico. O'Donojú shortly afterwards died; the Spanish government repudiated his act; and Spanish troops held the fortress of San Juan de Ulúa, off Vera Cruz, till 1827. A provisional Junta, nominated by Iturbide, issued a declaration of independence (Oct. 1821), and nominated a regency of five, with Iturbide as its president. The first Mexican Congress met on the 24th of February 1822. A section of it favoured a republic; another, monarchy under Iturbide; another, which was broken up by the refusal of Spain (continued until 1836) to recognize Mexican independence, monarchy under a Bourbon prince. A conflict now arose between the republican majority and Iturbide, which was settled by a military pronunciamiento in his favour, and the Congress elected him emperor. He was crowned on the 21st of July 1822. Fresh conflicts broke out between him and the Congress, and Antonio Lopez de Santa Anna, captain-general of Vera Cruz, proclaimed a republic, promising to support the Plan of Iguala. He was defeated at Jalapa and driven to Vera Cruz; but the army deserted Iturbide, who was compelled to abdicate (April 19, 1823). The Congress deported him to Italy, and granted him a pension. He returned, almost immediately, on the pretext that Spain was intriguing against Mexican independence, and on landing (having been previously outlawed) was arrested and executed (July 1, 1824).

President Guerrero, 1825-1831.

Santa Anna, Dictator, 1834.

Bustamante, President, 1837.

The Congress had meanwhile undone much of his work, and had divided into Federalists and Centralists, the latter largely Monarchists and Freemasons. The Federalists were strong enough to secure the adoption of a constitution (Oct. 4, 1824) modelled on that of the United States, with additional clauses, notably one declaring the Roman Catholic religion to be alone recognized. A source of abundant discord was opened by the provision that each state should contribute its quota to the Federal revenues. No proper statistical basis for estimating the quotas existed, and the device gave each state a plausible reason for attempting secession on occasion. Moreover, the capital and some territory round it was made into a "Federal district"—another grievance intensifying the antagonism of the state to the central power. The Freemasons had been largely instrumental in overthrowing Iturbide; they now divided into the Escoceses (lodges of the Scottish ritual), who were Monarchist and Centralist, and the Yorkinos, who took their ritual from New York, and their cue, it was alleged, from the American minister, Joel Poinsett. An attempt at revolt, headed by Nicolas Bravo, vice-president, the Grand Master of the Escoceses, was suppressed, but dissensions ensued in the Yorkino party between the followers of President Guerrero (a man largely of native blood, and the last of the revolutionary leaders) and of Gomez Pedraza, the war minister. A conflict broke out, the Guerrerists were victorious, and the pillage of foreign shops in Mexico City (1828), among them that of a French baker, gave a basis for the foreign claims which, ten years later, caused the "Pastry War" with France. Meanwhile, attacks on Spanish ships off Cuba by a Mexican squadron, commanded by an American, David Porter, had induced Spain to send an expedition to reconquer Mexico (1829) which was checked at Tampico by Santa Anna. During the invasion Vice-President Antonio Bustamante declared against President Guerrero; the bulk of the army supported him. Guerrero was deposed, and his partisans in the south were defeated at Chilpancingo (Jan. 2, 1831); and Guerrero, retiring to Acapulco, was enticed on board an Italian merchant-ship, and treacherously seized, tried and executed (Jan.–Feb. 1831). Next year, however, a revolt broke out against Bustamante, which was joined by Santa Anna, and eventually resulted in a pronunciamiento in favour of Gomez Pedraza. He, and his successor, Vice-President Gomez Farias (1833), assailed the exemption of the clergy and of military officers from the jurisdiction of the civil courts, and the latter attempted to laicize higher education and to relax monastic bonds. Santa Anna took advantage of the situation to assume the presidency. He eventually became dictator, dissolved Congress (May 31, 1834) and the state legislatures, and substituted creatures of his own for the governors of the states and mayors of towns, then retiring into private life. A new Congress, having resolved itself into a constituent assembly, followed up this Centralist policy (Dec. 30, 1836) by framing a new constitution, the Siete Leyes or Seven Laws, which converted the states into departments, ruled by governors appointed by the central authority, and considerably reduced popular representation. Antonio Bustamante became the first president under it. The French claims set up by the pillage of foreign shops in Mexico had, however, remained unsatisfied, and in 1838 a French fleet blockaded the coast, bombarded the fortress of San Juan de Ulúa, off Vera Cruz, and occupied the town. The Mexican government gave way, threatened by Federalist risings and secessions of states, which culminated in 1841. Santa Anna appeared, nominally as a

Santa Anna Restored, 1841.

mediator, and put forward the bases of Tacubaya (Sept. 28, 1841), abolishing all the Siete Leyes except the part relating to the judicial system, arranging for a new constituent assembly, and reserving for the president (himself) full power of re-organizing the administration. The Centralist government, after a vain attempt to defeat him by professing a more thorough Federalism, gave way to force, and Bustamante was allowed to leave the country. But the new Congress was too Federalist for Santa Anna, and he retired, leaving the reins to Nicolas Bravo, under whom a new Centralist constitution was established (1843). This expressly retained the privileges of the clergy and army, and was in some respects more anti-Liberal than that of 1836.

The Texas Question.

But new complications were now introduced by the question of Texas. Though a state of the Mexican Union, it had been settled from the United States in consequence of a land grant given by the Spanish viceroy to Stephen Austin in 1820, and had been estranged from Mexico partly by the abolition of slavery under a decree of President Guerrero, and partly by the prospect of the Centralist constitution of 1836. It then seceded. Santa Anna attempted to reduce it, showing great severity, but was eventually defeated and captured by Houston at the battle of San Jacinto, and compelled to sign a treaty recognizing Texan independence, which was disavowed on his return to Mexico. A state of war thus continued nominally between Mexico and its seceded member, whose independence was recognized by England, France and the United States. The slaveholders in the United States favoured annexation of Texas, and pressed the claims due from Mexico to American citizens, partly perhaps with the aim of forcing war. Most of these claims were settled by a mixed commission, with the king of Prussia as umpire, in 1840–1841, and a forced loan was raised to pay them in 1843, which stimulated the revolt of Paredes against Santa Anna, who had returned to power in 1844. It resulted in Santa Anna's downfall, imprisonment at Perote and eventual exile (Dec. 1844 to Jan. 1845), and the election of General José Joaquin Herrera as president. But Herrera was displaced in the last days of 1845 by a pronunciamiento in favour of Paredes, who undertook to uphold the national rights against the United States, and who was elected president on the 3rd of January 1846. Texas had meanwhile applied for admission into the American Union. The annexation, rejected in 1844 by the United States Senate, was sanctioned on the 1st of March 1845, and carried out on the 22nd of December 1845. The Mexican minister withdrew from Washington, and both sides made active preparations for war.

War with United States, 1846-48.

The United States forces were ordered by President Polk to advance to the Rio Grande in January 1846. They established a depot at Point Ysabel (behind the opening of Brazos Santiago), and erected a fort in Texan territory, commanding Matamoros, on the Mexican side of the Rio Grande. This provoked the Mexican forces into a defensive invasion of Texas, to cut the American communications with Point Ysabel. They were, however, defeated at Palo Alto (May 8) and Resaca de la Palma (May 9). There was an outburst of warlike feeling in the United States (with a counter-movement in the North), and an invasion of Mexico was planned by three routes—from Matamoros towards Monterey in New Leon, from San Antonio de Bexar to Chihuahua, and from Fort Leavenworth to New Mexico. Importance attaches chiefly to the movements of the first force under General Zachary Taylor. During the war preparations President Paredes, suspected of intriguing to overthrow the Republic and set up a Spanish prince, had to give place to his vice-president Bravo, who in his turn gave way before Santa Anna, who was hastily recalled from his exile at Havana to assume the presidency and the conduct of the war (Aug. 1846). He was allowed by the American squadron blockading Vera Cruz to pass in without hindrance. Probably it was thought his presence would divide the Mexicans.

Treaty of Peace.

The preparations of the United States took some months. It was not till the 5th of September 1846 that General Zachary Taylor could leave his depôt at Camargo on the Rio Grande, and march on Monterey. It was taken by assault on the 23rd of September; Santa Anna was defeated at Buena Vista (near Saltillo) on the 23rd of February 1847, and forced back on San Luis Potosí. New Mexico was occupied without opposition; Chihuahua was occupied, but not held, owing to the difficulties in maintaining communications; and Upper California was seized in the autumn of 1846 by John C. Fremont, who had been exploring a route across the continent, and by the United States Pacific squadron, and made secure by the aid of the New Mexico expedition. But as Mexico still continued to fight, it was determined to reach the capital via Vera Cruz. That city was taken by General Scott after a siege and bombardment (March 7 to 29, 1847); and after winning the battle of Cerrogordo (April 18), and a long delay at Puebla, Scott marched on Mexico City, stormed its defences against greatly superior forces, and effected an entrance after severe fighting on the 13th of September 1847. This virtually ended the war; Santa Anna was deprived of his command, and the treaty of Guadalupe Hidalgo, concluded on the 2nd of February 1848, ceded to the United States Texas, New Mexico and Upper California, in return for a payment of $15,000,000 by the United States to Mexico, and the assumption of liability by it for the claims of its subjects which it had hitherto been pressing against Mexico. This payment was doubtless intended to strengthen the United States' title to the conquered territory. It is generally admitted that Mexico was provoked into aggression in order that additional territory might be available for the extension of slavery.

Herrera, President, 1848-1851.

The American forces were withdrawn in May and June 1848 after the ratification of the treaty by Mexico. Under the presidency of Herrera (1848–1851) attempts were made to restore order and the public credit. An arrangement was effected with English holders of Mexican stock; an attempt was made to carry out a consolidation of the internal debt, which failed; the army was reduced and reorganized, and the northern frontier was defended by military colonies, formed partly of civilized Seminole Indians from the United States. But the financial situation was desperate; the federal revenue, mostly from customs—which were evaded by extensive smuggling—was not half the expenditure; and Indian revolts in Yucatan (1847–1850) and in the Sierra Gorda had added to the strain. Arista succeeded Herrera as president (Jan. 1851), but resigned (Jan. 1853).

Santa Anna in Power, 1853-1854.

After a sort of interregnum (Jan.–March 1853) Santa Anna was recalled (by a vote of the majority of the states under the Plan of Arroyozarco, on the 4th of February 1853, the result of a pronunciamiento), and made dictator in the interests of federation. His measures, partly inspired by an able Conservative leader, Lucas Alaman, proved strongly Centralist: one is especially noteworthy, the establishment of the ministry of "fomento," or encouragement to public works, education, and intellectual and economic development, which is a conspicuous aid to Mexican welfare to-day. He also negotiated (at the end of 1853) the sale of the Mesilla valley (now Arizona) to the United States, but the purchase money was soon dissipated. On the 16th of December 1853 Santa Anna issued a decree making himself dictator, with the title of serene highness. On the 1st of March 1854, at Ayutla in Guerrero, a section of the army under Colonel Villareal proclaimed the Plan of Ayutla, demanding Santa Anna's deposition and the establishment of a provisional government to secure a new constitution. Among the leaders in the movement were Generals Alvarez and Comonfort, and it is said that Porfirio Diaz, subsequently president, then a young soldier, made his way to Benito Juarez, then in prison, and arranged with him the preliminaries of the revolt. It spread, and Santa Anna left the country (Aug. 1854).[1]

Two filibustering expeditions at this time—one by William Walker, afterwards notorious in Nicaragua, in Lower California

---

[1] Santa Anna tried to get back to politics in Mexico after Maximilian's fall, without success. He was amnestied with other exiles in 1874, and died in obscurity in 1876.

(Dec. 1853), the other by Count Raousset de Boulbon in Sonora (July 1854)—added to the general disorder.

Benito Juarez.

The provisional president, General Carrera, proving too Centralist, was replaced by Alvarez (Sept. 24, 1855), two of whose ministers are conspicuous in later history—Ignacio Comonfort, minister of war, and Benito Juarez, minister of finance. Juarez (b. 1806) was of unmixed Indian blood. The son of a Zapotec peasant in a mountain village of Oaxaca, he was employed as a lad by a bookbinder in Oaxaca city, and aided by him to study for the priesthood. He soon turned to the law, though for a time he was teacher of physics in a small local college; eventually went into politics, and did excellent work in 1847 as governor of his native state. Juarez almost immediately secured the enactment of a law (Ley Juarez, Nov. 23, 1855) subjecting the clergy and the army to the jurisdiction of the ordinary courts. "Benefit of clergy" was the curse of Mexico. Officers and soldiers could be tried only by courts-martial, the clergy (including numbers of persons in minor orders, who were practically laymen) only by ecclesiastical courts. The proposed reform roused the Clericals to resistance. Alvarez gave place (Dec. 8, 1855) to his war minister Comonfort, who represented the less anti-Clerical Liberals. He appointed a commission to consider the question of draining the valley of Mexico, which adopted the plan ultimately carried out in 1890–1900; suppressed a Clerical rising in Puebla (March 1856), which was punished by a considerable confiscation of church property; sanctioned a law releasing church land from mortmain, by providing for its sale, for the benefit, however, of the ecclesiastical owners (called after its author Miguel Lerdo de Tejada, brother of the subsequent president), and a new draft constitution, largely modelled on that of the United States (Feb. 5, 1857). The clergy protested violently, and the Plan of Tacubaya (Dec. 17, 1857), which made Comonfort dictator, provided for the construction of a new constitution under his auspices. He was presently displaced by a thorough reactionary, General Zuloaga, and expelled from Mexico early in 1858; and for three years Mexico was a prey to civil war between two rival governments —the Republicans at Vera Cruz under Juarez, who, as Chief Justice of the Supreme Court, succeeded Comonfort; and the reactionaries at the capital. The latter were at first presided over by Zuloaga, who, proving incompetent, was replaced at the end of 1858 by Pezuela, who early in 1859 gave place to Miguel Miramon, a young, able and unscrupulous soldier who was shortly afterwards accepted as "constitutional" president by his party. The Juarists were defeated outside the city of Mexico twice, in October 1858 and on the 11th of April 1859.

Miramon.

On the second occasion the whole body of officers, who had surrendered, were shot with Miramon's authority, if not by his express orders, together with several surgeons (including one Englishman, Dr Duval) (the fifty-three "martyrs of Tacubaya"). This atrocity caused great indignation in Mexico and abroad: the reactionists were divided; their financial straits were extreme, as the Juarists held all the chief ports. Juarez was recognized by the United States, and allowed to draw supplies of arms and volunteers thence; and in July 1859 he published laws suppressing the religious orders, nationalizing ecclesiastical property (of the estimated value of $45,000,000), establishing civil marriage and registration, transferring the cemeteries to civil control, and, in short, disestablishing the church. But the apparent hopelessness of any ending to the conflict, together with the frequent outrages of both parties on foreigners, afforded strong reasons for foreign intervention. Early in 1859 President Buchanan had recommended the step to Congress, which did not respond. On the 12th of December 1859 the M'Lean-Juarez treaty was concluded, which gave the United States a sort of disguised protectorate over Mexico, with certain rights of way for railroads over the Isthmus of Tehuantepec and between the Rio Grande and Pacific. The American Senate, however, did not ratify the treaty, and a motion for its reconsideration late in 1860 came to nothing, owing to the approach of the War of Secession.

When Napoleon III. was in captivity at Ham he dreamed of a Central America civilized and opened up to modern enterprise by a transoceanic canal: and the clerical refugees in Paris, among them Labastida, archbishop of Mexico, easily influenced the Empress Eugénie, herself a Spaniard, to interest her husband in the cause of centralized monarchy and the church: it is said that even in 1859 they had thoughts of setting up the Archduke Maximilian as ruler of Mexico.

Overthrow of Miramon, 1860.

The question of a joint intervention of Great Britain, France, Spain and Prussia was mooted between those powers in 1860. Early in 1859 the outrages on British subjects had caused the British minister to break off diplomatic relations. Forced contributions had been levied by both sides on goods or bullion, being European property, the reactionaries being the worst offenders; and there were numerous cases of murder and robbery of Europeans. At last, on the 17th of November 1860, Miramon, under the plea of necessity, seized $630,000 in specie which had been left under seal at the British Legation and was intended for the bondholders. On the 22nd of December 1860 his forces were routed by the Juarist general Ortega at Arroyozarco, and his government was overthrown.

European Intervention, 1861.

Juarez entered Mexico City on the 11th of January 1861. He soon found that his government was held responsible to Europe for the excesses of its rival as well as its own. Miramon's government had violated the British Legation; the Spanish minister, the papal legate and the representatives of Guatemala and Ecuador were expelled from the country for undue interference on behalf of the reactionaries; the payments of the British loan were suspended by Juarez's Congress in July 1861; and various outrages had been committed on the persons and property of Europeans for which no redress could be obtained. The French *chargé d'affaires*, Dubois de Saligny, who had been sent out in November 1860, urged French intervention, and took up the Jecker claims. Jecker, a Swiss banker settled in Mexico, had lent Miramon's government in 1859 $750,000 (subject, however, to various deductions): in return, Miramon gave him 6% bonds of the nominal value of $15,000,000 which were ingeniously disguised as a conversion scheme. Jecker had failed early in 1860, Miramon was overthrown a few months later. Jecker's creditors were mostly French, but he still held most of the bonds, and there is reason to believe that he won over Dubois de Saligny by corrupt means to support his claims. Intercepted correspondence (since confirmed from the archives of the Tuileries) showed that the Duc de Morny promised Jecker his patronage in return for 30% of the profits (De la Gorce, *Hist. du Second Empire*, IV. c. 1). An imperial decree naturalized Jecker in France, and Napoleon III. took up his claim. A convention between Great Britain, France and Spain for joint interference in Mexico was signed in London on the 31st of October 1861. A separate arrangement of the British claims was negotiated by Juarez, but rejected by the Mexican Congress, November 1861; and the assistance of the United States with a small loan was declined, Mexican territory being demanded as security. On the 14th of December Vera Cruz was occupied by Spanish troops under General Prim; the French fleet and troops arrived soon after, with instructions to seize and hold the Gulf ports and collect the customs for the three Powers till a settlement was effected; Great Britain sent ships, and landed only 700 marines. In view of the unhealthiness of Vera Cruz, the convention of Soledad was concluded with the Mexican government, permitting the foreign troops to advance to Orizaba and incidentally recognizing Mexican independence. But as the French harboured leaders of the Mexican reactionaries, pressed the Jecker claims and showed a disposition to interfere in Mexican domestic politics, which lay beyond the terms of the joint convention, Great Britain and Spain withdrew their forces in March 1862.

More troops were sent from France. Their advance was checked by Zaragoza and Porfirio Diaz in the battle of Cinco de Mayo, on the 5th of May 1862; and in September of that year 30,000 more French troops arrived under General Forey. Wintering at Orizaba, they recommenced their advance

(Feb. 17, 1863), besieged and reduced Puebla, and entered Mexico City on the 7th of June. A provisional government of Mexicans, nominated directly or indirectly by Dubois de Saligny, adopted monarchy, offered the crown to Maximilian of Austria, brother of the Emperor Francis Joseph, and should he refuse, left its disposal to Napoleon III.

French Expedition, 1862-63.

Maximilian Emperor, 1864.

Maximilian, after some difficulty as to renouncing his right of succession to the throne of Austria, accepted the crown subject to the approval of the Mexican people, and reached Mexico city on the 12th of June 1864. Juarez meanwhile had set up his capital, first in San Luis Potosí, then in Chihuahua. The new empire was unstable from the first. Before Maximilian arrived the provisional government had refused to cancel the sales of confiscated Church lands, as the clericals demanded. When he came, a host of new difficulties arose. A new loan, nominally of about eight millions sterling, but yielding little more than four, owing to discount and commission, was raised in Europe, but no funds were really available for its service. Maximilian carried the elaborate etiquette of the court of Vienna to Mexico, but favouring toleration of Protestantism, and the supremacy of the Crown over the Church, he was too liberal for the clericals who had set him up. As a foreigner he was unpopular, and the regiments of Austrians and Belgians which were to serve as the nucleus of his own army were more so. His reforms, excellent on paper, could not be carried out, for the trained bureaucracy necessary did not exist. For a time he nominally held sway over about two-thirds of the country—roughly, from lat. 18° to 23°, thus excluding the extreme north and south. Oaxaca city, under Porfirio Diaz,[1] capitulated to Bazaine—who had superseded the too pro-clerical Forey in October 1864—in February 1865, and by the autumn of that year the condition of the Juarists in the north seemed desperate. But the towns asked for permanent French garrisons, which were refused, as weakening their own power of self-defense. Instead, the country was traversed by flying columns, and the guerillas dealt with by a French service of "contre-guerilla," who fought with much the same savagery as their foes. Directly the French troops had passed, Republican bands sprang up, and the non-combatant Mexicans, to save themselves, could only profess neutrality. Yet on the 3rd of October 1865, Maximilian, misled by a false report that Juarez had left the country, issued a decree declaring the Juarists guerillas, who, whenever captured, were to be tried by court-martial and shot. Mexican generals on both sides had done as much. But Maximilian's decree prepared his own fate.

Maximilian deserted by France.

The American Civil War ended in the spring of 1865, and a strong popular feeling was at once manifested in favour of asserting the Monroe doctrine against Maximilian's government. In the summer there were threatening movements of United States troops towards the Rio Grande; early in 1866 Napoleon III. announced his intention of withdrawing his forces; in response to a note of Seward, the United States secretary of state, of the 12th of February 1866, he was induced to promise their return by three instalments—in November 1866, March and November 1867. Maximilian now turned for support to the Mexican clericals; meditated abdication, but was dissuaded by his wife Charlotte, the daughter of Leopold I. of Belgium (and "the better man of the two," as he had once jestingly said), who went to intercede for him with the emperor of the French. Finding him obdurate, she went on to appeal to the pope; while at Rome she went mad (end of September 1866).

Execution of Maximilian, 1867.

Maximilian had meanwhile drawn nearer to the clericals and farther from the French, and, to protect French interests, Napoleon III. had decided to send out General Castelnau to supersede Bazaine, arrange for the withdrawal of the French forces in one body, and restore the Republic under Ortega, who had quarrelled with Juarez, and was therefore, of all republicans, least unacceptable to the clericals. But fearing the prospect, they induced Maximilian, who had retired to Orizaba for his health, to remain. He yielded on condition that a congress of all parties should be summoned to decide the fate of the empire. Hereupon he returned to the capital; the Juarist dominion extended rapidly; the French troops left (in one body) on the 5th of February 1867, and shortly after Maximilian took command of the army at Querétaro. Here, with Miramon, he was besieged by the Juarists under Escobedo, and the garrison, when about to make a last attempt to break out, was betrayed[2] by Colonel Lopez to the besiegers (May 15, 1867). Maximilian, with the Mexican generals Miramon and Mejia, was tried by court-martial, and, refusing (or neglecting) to avail himself of various opportunities of escape, was convicted on charges which may be summarized as rebellion, murder and brigandage, on the 14th of June, and shot, with Miramon and Mejia, on the 19th of June 1867, despite many protests from European governments and prominent individuals, including Garibaldi and Victor Hugo. (An effort to save him made by the U.S. Government was frustrated by the dilatoriness of the U.S. Minister accredited to Juarez's Government.) After considerable difficulty with the Republican Government, his body was brought to Europe.

Juarez President.

Death of Juarez, 1872.

Administration of Lerdo de Tejada.

Porfirio Diaz President, 1877.

Meanwhile Porfirio Diaz had captured Puebla (April 2) and besieged Mexico City, which fell on the 21st of June. The last anti-Juarist stronghold (Inayarit) submitted on the 20th of July 1867. A good deal of discontent existed among the republican rank and file, and Juarez's election in October to the presidency was opposed by Diaz's friends, but without success. But so soon as Juarez was elected, insurrections broke out, and brigandage prevailed throughout the following year. There were unsuccessful insurrections also in 1869 (clerical) and 1870 (republican), but an amnesty, passed on the 13th of October 1870, helped to restore peace; trouble again arose, however, at the 1871 election, at which the candidates were Juarez, Sebastian Lerdo de Tejada and Diaz. Juarez's continued re-election was regarded as unconstitutional, and no party obtaining a clear majority, the matter was thrown into Congress, which elected him. Diaz's supporters refused to recognize him, and a revolution broke out, which went on sporadically till Juarez's death on the 18th of July 1872. Sebastian Lerdo de Tejada, as president of the Supreme Court, succeeded him, and amnestied the rebels, but made no further concessions. In the next year, however, laws were passed repeating in a stronger form the attacks of 1857 on the supremacy of the Church, and prohibiting monastic life. The first day of 1873 was marked by the opening of the Vera Cruz & Mexico railway. Protestant missions established themselves (with some opposition) in the country, and diplomatic relations were renewed with France and Spain (1874). But towards the close of Lerdo de Tejada's term he was suspected of aiming at a dictatorship, and Diaz, whom he had proscribed, made preparations for a rising, then retiring to Texas. At the beginning of 1876 the revolution broke out in Oaxaca with the plan of Tuxtepec, which was adopted by Diaz, and proclaimed as the plan of Palo Blanco (March 21). Diaz's attempt to raise the north, however, failed, and, trying to reach Vera Cruz by sea, he was recognized on the steamer, and recaptured while attempting a four-mile swim ashore. The purser, however, made it appear that he had again jumped overboard, concealed him for some days—generally inside one of the saloon sofas—and helped him to get ashore in disguise at Vera Cruz. He then escaped to Oaxaca and raised a force. Lerdo was declared re-elected, but was overthrown by Diaz after the battle of Tecoac (Nov. 16, 1876) and forced into exile (Jan. 1877), and Diaz was declared president on the 2nd of May 1877. A law forbidding the re-election of a president till four years had elapsed from his retirement from office was passed in the autumn of that year.

---

[1] Diaz refused parole, and was confined at Puebla for some months, but made his escape, and was soon in the field again.

[2] Lopez said he acted as Maximilian's agent, but his story rested on an alleged letter from Maximilian which was discredited as a forgery. The evidence of his treason was published in *El Nacional* of Mexico, Sept. 11, 1887.

Diaz's first presidency (1870–1880) was marked by some unsuccessful attempts at revolution notably by Escobedo from Texas in 1878, and by a more serious conspiracy in 1879. Diplomatic relations were resumed with Spain, Germany, Italy and some South American states (1877), and France (1880). There were some frontier difficulties with the United States, and with Guatemala, which revived a claim dropped since 1858 to a portion of the state of Chiapas; and there was considerable internal progress, aided by a too liberal policy of subsidies to railways and even to lines of steamships. The boundary questions were settled under President Gonzalez (1880–1884); relations with Great Britain were renewed in 1884. The claims of the railways, however, necessitated retrenchment on official salaries, and the president's plan for conversion of the debt roused unexpected and successful opposition in an ordinarily subservient Congress. At the end of 1884 Porfirio Diaz was again elected president, and was continually re-elected, the constitution being modified expressly to allow him to continue in office.

Mexico under Diaz.

Financial reorganization.

The history of Mexico from 1884 to 1910 was almost void of political strife. President Diaz's policy was to keep down disorder with a strong hand; to enforce the law; to foster railway development and economic progress; to develop native manufactures by protective tariffs; to introduce new industries, *e.g.* the production of silk and wine, of coca and quinine; to promote forestry; to improve elementary and higher education—for all which purposes the Ministerio del Fomento is a potent engine; to encourage colonization; and, above all, to place the national credit on a sound basis. The first step in this process was a settlement of the British debt by direct arrangement with the bondholders. In 1890 the Spanish bondholders' claims were satisfactorily arranged also. In 1891 the tariff was made more protectionist. In 1893 the depreciation of silver necessitated stringent retrenchment; but the budget balanced for the first time during many years, the floating debt was converted, and a loan raised for the completion of the Tehuantepec Railway. After 1896 substantial annual surpluses were spent in reducing taxation and in the extinction of debt. In 1895 the 6% external debt was converted into a 5% debt, the bonds of which remained at a premium for 1902; in 1896 the alcabalas or interstate customs and municipal *octrois* were abolished, and replaced in part by direct taxation and increased stamp duties.

Pacification of the Country.

The institution by Diaz of the *guardias rurales*, a mounted gendarmerie composed of the class who in former days drifted into revolution and brigandage, was a potent means of maintaining order, and the extension of railways and telegraphs enabled the government to cope at once with any disturbance. The old local revolutions practically disappeared. In 1886–1887 there were some disturbances in Coahuila, New Leon, Sinaloa and Tamaulipas; subsequently hardly anything was heard of such disorders except on the Texan frontier, where in 1890 Francisco Ruiz Sandoval and in 1891 Catarino Garza made incursions into Mexico. Occasionally the Church gave trouble—the presence of foreign priests was complained of; attempts to evade the law prohibiting conventual life were detected and foiled (1891, 1894); and there were Indian risings, repressed sometimes with great severity, among the Mayas of Yucatán, whose last stronghold was taken in 1891, and the Yaquis of Sonora (1899–1900). Under federal and democratic forms, Diaz exercised a strictly centralized and personal rule. He was invited to approve the candidates proposed for state governorships; in all law cases affecting the Government or political matters the judges asked his opinion; he drafted bills, and discussed their text with individual members and committees of congress. Similarly, the state legislatures, as well as the judges and municipal officers, were actually or virtually selected by the state governors, who were practically agents of the president. Now and then the old passions broke out: in September 1898 an absurd attempt to assassinate President Diaz was made by a countryman named Arroyo, but discontent with Diaz's rule was apparently confined to a small minority.[1] In 1909 indeed there were some disquieting symptoms. Owing to Diaz's age the vice-presidency had been revived in 1904, and Don Ramon Corral elected to it; but at the elections of 1909 a movement arose in favour of replacing him by General Bernardo Reyes, Governor of Nuevo Leon, but he was disposed of by an official commission to study the military systems of Europe. It was, therefore, regarded as certain that, should President Diaz die in office, Señor Corral would succeed him without serious difficulty.

Foreign Affairs.

In foreign affairs the rule of Diaz was uneventful. There were transient disputes with the United States (1886, 1888). In 1888–1890 and 1894–1895 a boundary dispute with Guatemala became serious. But Guatemala gave way at the threat of war (Jan. 1895) and a new treaty was made (April 1, 1895). Again in 1907 there was some friction owing to the murder of a Guatemalan ex-president by a compatriot in Mexico: later in the year, however, the Mexican government was active in stopping a war between its Central American neighbours. In the difficulty between England and the United States over the Venezuelan boundary (Dec. 1895) Mexico expressed strong adherence to the Monroe doctrine in the abstract, and suggested that its maintenance should not be left wholly to the United States, but should be undertaken by all American Powers. The first Pan-American congress met in Mexico City in 1901, and the country was represented at the second, held in Rio Janeiro in 1906. Mexico also took part in establishing the permanent Central American Court of Arbitration, inaugurated on the 25th of May 1908 at Cartago, Costa Rica, under the Washington treaties of December 1907, and showed readiness to associate herself with the Government of her great northern neighbour in preserving peace among the Central American States. On the 17th of October 1909 President Taft and President Diaz exchanged visits at the frontier at El Paso, Texas.

Economic Progress.

In brief, under President Diaz's rule the history of Mexico is mainly economic. In the six financial years 1893–1894 to 1899–1900 inclusive the yield of the import duties increased by upwards of 80%; the revenue from stamps over 60%, though the duties were reduced; the postal revenue from 1895–1896 to 1899–1900 rose 60%; the telegraph revenue over 75%. Again, in 1898–1899 the total ordinary revenue of the state was £6,013,921; in 1906–1907 it had increased to £11,428,612, or by more than 90%, and though 1907–1908 was a year of depression its total revenue (£11,177,186) exceeded that of any year save its immediate predecessor. The great drainage scheme which completed the works of the 17th century by taking out the surplus waters of the southern lakes of the valley of Mexico was devised in 1856, begun under Maximilian, proceeded with intermittently till 1885, then taken up with improved plans, practically completed by 1896, and inaugurated in 1900;[2] the harbour of Vera Cruz was finished in 1902; the Tehuantepec railway, likely to prove a formidable rival to any interoceanic canal, was opened on the 24th of January 1906. All three were the work of an English firm of contractors, the head of which was Sir Weetman Pearson. American, and later Canadian, capital and enterprise have also been very largely concerned in the development of the country; and its progress was not permanently interfered with by the great earthquakes of April 1907 and July 1909 at Acapulco, and the floods in August 1909 at Monterey. In 1891 elementary education was reorganized, and made compulsory, secular and gratuitous. Great attention has been paid to higher education, and—at least in the hospitals—to modern sanitation and hygiene.

AUTHORITIES.—For English readers the standard work is H. H. Bancroft, *Collected Works* (Histories of the Pacific States, Central America, &c., vols. x.–xiv. (Mexico, 1521–1887) with vols. xv., xvi.

---

[1] Don Augustin Iturbide, grandson of the emperor, godson and (perhaps) at one time the destined heir of Maximilian, was turned out of the army and imprisoned in 1890 for abusing President Diaz.

[2] For a full account of the works see J. B. Body in *Proceedings of the Institution of Civil Engineers*, cxliii. 286, sqq.

(Texas), and vol. xvii. (New Mexico, &c.). Mention may also be made of Gaston Routier's *Histoire de Mexique* (1895). Standard Mexican authorities are: C. M. de Bustamante, *Quadro historico de la revolucion mexicana*, 6 vols. (Mexico, 1832–1846); Lucas Alaman, *Historia de Mexico* (Mexico, 1849–1852); N. de Zamacois, *Historia de Mexico desde sus tiempos mas remotos hasta nostras dias*, 19 vols. (Barcelona, 1876–1882); J. E. Hernández y Davalos, *Coleccion de documentos para la historia de la Independencia* (Mexico, 6 vols). A huge and informative illustrated work, edited by Justo Sierra (3 vols. large 4to), sumptuously produced and badly translated, is *Mexico, its Social Evolution* (Barcelona, 1900–1904); a useful and handy chronicle is Nicolas Leon's *Compendio de la historia general de Mexico hasta el año de 1900* (Mexico and Madrid, 1902). For the colonial period, Alexander v. Humboldt, *Essai politique sur la royaume de la Nouvelle Espagne* (Paris, 1811, 2 vols., and atlas; also an English translation). For the war with the United States see R. S. Ripley, *The War with Mexico* (New York, 1849); E. D. Mansfield, *The Mexican War* (New York, 1849); and Winfield Scott's *Memoirs*. For Maximilian, the Blue-books on Mexican affairs contained in *Accounts and Papers* (presented to parliament), vol. lxv. 1862, and vol. lxiv. 1863, are valuable; E. de Kératry, *La Créance Jecker; l'empereur Maximilien, son élévation et sa chute* (translated into English by Venables); *La Contre-guerilla française au Mexique*, are specially noteworthy; Prince Felix Salm-Salm's *Diary* gives valuable information as to Maximilian's decline and fall. Also Dela Gorce, *Histoire du second empire*, vols. iv. v.; J. F. Domenech, *L'Empire mexicain* (Mexico, 1866), and *Le Mexique tel qu'il est* (Paris, 1867); Daran, *El General Miguel Miramon* (in French) (Rome, 1886); Schmidt von Tavera, *Gesch. d. Regierung d. Kaisers Maximilian I.* (Vienna, 1903). Ulick Ralph Burke's *Life of Benito Juarez* (London, 1894) is of considerable value and interest. For the period since 1887 information in English must be sought chiefly in magazine articles: Matias Romero, "The Garza Raid and its Lessons," *North American Review* (Sept. 1892); Don Agustin Iturbide, "Mexico under Diaz," ibid. (June 1894); Romero, "The Philosophy of Mexican Revolutions," ibid. (Jan. 1896); and C. F. Lummis, "The Awakening of a Nation" (New York, 1898, previously in *Harper's Magazine*), are valuable as giving information (especially the last named) and points of view. Van Dyke, "Politics in Mexico," *Harper's Magazine* (1885), vol. lxxi., gives particulars of the opposition to Gonzalez's debt conversion scheme of 1884. President Diaz's message of November 1896, giving an account of his stewardship from 1884 to that year, has been translated into French (*Rapport du Général Porfirio Diaz . . . à ses compatriotes sur les actes de son administration, &c.*), edited by Auguste Génin (Paris, 1897). The early constitutions of the Republic have been published (in Spanish) in three volumes; a study of that of 1857 by B. Moses (of the University of California) is in the *Annals of the American Academy of Political Science*, II. i. 1891. Various books, chiefly American, have been written on Mexico of late years from a tourist's standpoint. Mrs Alec Tweedie's *Mexico as I saw it* (London, 1901) and *Life of Porfirio Diaz* (1906) contain valuable information personally obtained from good authorities in Mexico. See also Percy F. Martin, *Mexico of the Twentieth Century*, 2 vols. (London, 1907); and C. R. Enock, *Mexico* (1909). (J. S. Ma.)

MEXICO, a state of the republic of Mexico, bounded N. by Hidalgo, E. by Tlaxcala and Puebla, S. by Morelos and Guerrero, and W. by Michoacán. Pop. (1900), 934,468, largely Indian. Area, 9247 sq. m., a large part of which lies within that great depression of the Mexican plateau known as the Valley of Mexico. Enclosed within its boundaries, except on the south, is the Federal District and capital city of Mexico with an area of 463 sq. m., which is not included in that of the state. The state is divided into two unequal parts by the Sierra de Ajusco and Montes de las Cruces, which form a wooded ridge across it from east to west, with a general elevation of about 10,000 ft. above sea-level, or about 2500 above the plateau level. These ranges are part of a broken irregular chain which sometimes bears the name of Anahuac. A considerable part of the northern plateau consists of a broad plain, once the bed of a great lake but now covered with swamps, sodden meadows and lakes. The surrounding country drains into this depression, but an artificial outlet has been created by the opening of the Tequixquiac tunnel. Beyond its margin the plateau drains westward to the Pacific through the Lerma, and north-east to the Gulf through the San Juan and Pánuco. South of the Sierra de Ajusco the country is roughly mountainous and drains to the Pacific through tributaries of the Balsas. Within the lacustrine depression of the north are the lakes of Zumpango, San Cristobal, Xaltocán, Chalco, Xochimilco, and Texcoco, the latter three lying partly or wholly in the Federal District. Texcoco has the lowest level and its water is brackish and undrinkable, though that of the streams flowing into it and of the other lakes is sweet. Lake Xochimilco is celebrated for its "floating gardens" or *chinampas* (see Mexico, Federal District of). The principal industries of the state are agricultural, and the principal products are cereals, sugar, maguey (from which "pulque" is made), coffee, and fruit. Stock-raising has also had a profitable development, owing to the proximity of the national capital. The manufacturing industries are important; among the manufactures are cotton and woollen fabrics, flour, dairy products, glass-ware, pottery, bricks, wines and spirits. The making of "pulque" from the sap of the maguey plant (*Agave americana*) is the chief industry of the state, and the product is exported in large quantities to the national capital. The state is traversed by the Central, National, Mexican International and Interoceanic railways, and by short lines from the national capital to neighbouring towns. The capital is Toluca, and other important towns are Zumpango (pop. 5942 in 1900), 30 m. N. of the national capital, Tenango del Valle (5881 in 1900), 15 m. S.E. of Toluca, and Lerma (estimated, 7200), near the western frontier of the state.

MEXICO, a city and the county-seat of Audrain county, Missouri, U.S.A., N.E. of the centre of the state, and about 110 m. N.W. of St Louis. Pop. (1890), 4789; (1900), 5099, including 948 negroes and 111 foreign-born; (1910), 5939. It is served by the Chicago & Alton, the Chicago, Burlington & Quincy, and the Wabash railway systems. Mexico is the seat of Hardin College and Conservatory of Music (Baptist, 1873), for young women, an institution founded and endowed by Charles H. Hardin (1820–1892), governor of the state in 1872–1874, and of the Missouri Military Academy (1889). The city is situated in the blue grass region of Missouri, and is a shipping-point for horses and mules. Among the manufactures are flour, shoes and fire-clay products. Mexico was laid out as "New Mexico" in 1836, and became the county-seat under its present name in 1837. It was incorporated as a town in 1855, was entered by the Wabash road in 1858 and by the Alton in 1872, and was first chartered as a city in 1874.

MEXICO CITY, capital of the Republic of Mexico and chief town of the Federal District, near the southern margin of the great central plateau of Mexico, in lat. 19° 25′ 45″ N., long. 99° 7′ W. It is about 200 m. in a direct line W. by N. of Vera Cruz, its nearest port on the Gulf of Mexico, with which it is connected by two railway lines, one of which is 264 m. long; and about 181 m. in a direct line N.N.E. of Acapulco, its nearest port on the Pacific, with which it is connected partly by rail and partly by a rough mountain trail (the *camino real*) to the coast. Pop. (1900), 344,721.

The city stands on a small plain occupying the south-western part of a large lacustrine depression known as the Valley of Mexico (*El Valle de Mêxico*), about 3 m. from the western shore of Lake Texcoco, whose waters once covered a considerable part of the ground now occupied by the city. The Valley, including the drainage basin of Lake Zumpango, has an area of 2219 sq. m. (1627 sq. m. without that basin). The elevation of the city above sea-level is 7415 ft., only a few feet above the level of Lake Texcoco. The general elevation of the Valley is about 7500 ft., that of Lake Zumpango being 7493 ft., and of Lake Chalco 7480 ft. The rim of the Valley is formed by spurs of the transverse cordillera on the north and south sides—the Sierra de Guadalupe (650 to 750 ft. above the city) on the north, and the Sierra Nevada with its snow-clad peaks of Popocatapetl and Ixtaccihuatl farther away to the south-east—and by a part of the Sierra de Ajusco, known as the Montes de las Cruces, from which the greater part of the city's water supply is derived. Lake Texcoco (*Tezcoco* or *Tezcuco*) is a comparatively shallow body of brackish water, with an area of about 11½ sq. m., and is fed by a number of small streams from the neighbouring mountains, and by the overflow of the other lakes. Its shores are swampy and desolate and show considerable belts of saline incrustations with the fall in its level. The Aztecs settled there because of the security afforded by its islands and shallow waters—their city, Tenochtitlán, being so completely surrounded by water that a handful of warriors could easily defend its approaches against a greatly superior force. The Chalco and Xochimilco lakes, 8 or 9 m. to the southward, which are separated by a narrow ridge of land, are connected with the lower part of the city by an artificial canal, called "La Viga," 16 m. long and 30 ft. wide, which serves as an outlet for the overflow of those lakes and as a waterway for the natives who bring in flowers and vegetables for sale. Lake Xochimilco, celebrated for its *chinampas*, or "floating gardens" (see MEXICO, FEDERAL DISTRICT OF), is supplied very largely by fresh-water springs opening within the lake itself, which the city has partially diverted for its own water supply. Lake Chalco is also greatly reduced in size by railway fillings and irrigation works, to the great distress of the natives who have gained their living by fishing in its waters since long before the Spanish conquest.

The climate of the city is temperate, dry and healthful. The temperature ranges from a minimum of 35° F. in winter to a maximum of 79° in summer. The winter range is 35° to 68°, and the summer 50° to 79°. The nights are always cool. The year is divided into a wet and dry season, the former from April to September, the latter from October to March. The rainfall, however, is light, about 20 to 25 in., but, with the assistance of irrigation, it serves to sustain a considerable degree of cultivation in the neighbourhood of the city. The health of the city, unfortunately, does not correspond with its favourable climatic conditions. With a wet, undrained subsoil and a large population of Indians and half-breeds living in crowded quarters, the death-rate has been notoriously high, though the completion of the Valley drainage works in 1900, supplemented by underground sewers in the better parts of the city, and by better sanitation, have recently improved matters. The annual death-rate per 1000 was 54 per 1000 for the Federal District in 1901, 50 in 1902, 48 in 1903, 46 in 1904, and 56 in 1905; the increase for the last-mentioned year being due to an epidemic of typhus fever.

The city is laid out with almost unbroken regularity and is compactly built—the streets running nearly with the cardinal points of the compass. The new and better residence sections are on the western side; the poorer districts are on the eastern side nearer the swampy shores of Lake Texcoco. As the name of a street changes with almost every block, according to the old Spanish custom, a list of street names is sometimes mistakenly accepted as the number of continuous thoroughfares in the city, so that it has been said that Mexico has 600 to 900 streets and alleys. An attempt was made in 1889 to rename the streets—all running east and west to be called *avenidas*, all running north and south *calles*, and all continuous thoroughfares to have but one name—but the people clung so tenaciously to the old names that the government was compelled to restore them in 1907. Outside the Indian districts of the eastern and southern outskirts, the streets are paved with asphalt and stone, lighted with electricity and gas, and served with an efficient street railway service. The political and commercial centre of the city is the Plaza Mayor, or Plaza de la Constitución, on which face the cathedral, national palace, and municipal palace. Grouped about the Plaza de Santo Domingo are the old convent and church of Santo Domingo, the court of the Inquisition now occupied by the School of Medicine, the offices of the Department of Communicaciones, and the old custom-house (*aduana*). Close by are the old church of the Jesuits and the mechanics' school (*artes y oficios*) with its large and well-equipped shops. Among other well-known *plazas* are: Loreto, on which faces the great enclosed market of the city; Guardiola, in the midst of handsome private residences; San Fernando, with its statue of Vicente Guerrero; and Morelos, with its marble statue of the national hero of that name. The Paseo de la Reforma, the finest avenue of the city, is a broad boulevard extending from the Avenida Juárez south-west to Chapultepec, a distance of nearly three miles. At intervals are circular spaces, called "glorietas," with statues (the famous bronze equestrian statue of Charles IV., and monuments to Columbus, Cuauhtemoc the last of the Aztec emperors, and Juárez). Other notable avenues are Bucareli and Juárez, and the Avenida de la Viga, which skirts the canal of that name. The principal business streets runs westward from the Plaza Mayor toward the Alameda, and is known as the Calle de los Plateros (Silversmiths' Street) for two squares, Calle de San Francisco for three squares, and Avenida Juárez along the south side of the Alameda to its junction with the Paseo. The Alameda, or public garden, ½ m. west of the Plaza Mayor, covers an area of 40 acres, and occupies the site of the old Indian market and place of execution, where occurred the first auto-da-fé in Mexico in 1574.

The great cathedral stands on or near the site of the Aztec temple (*teocalli*) destroyed by Cortés in 1521. The foundations were laid in 1573, the walls were completed in 1615, the roof was finished in 1623, its consecration took place in 1645 and its dedication in 1667, the towers were completed in 1791, and the great church was finished about 1811. It is 426 ft. in length by 197 ft. in width, and its towers rise to a height of 204 ft. Its general plan is that of a Greek cross, with two great naves and three aisles, twenty side-chapels and a magnificent high altar supported by marble columns and surrounded by a tumbago balustrade with sixty-two tumbago statues carrying elaborate candelabra made from a rich alloy of gold, silver and copper. The elaborately carved choir is also enclosed by tumbago railings made in Macao, weighing 26 tons. The vaulted roof is supported by twenty Doric columns, 180 ft. in height, and the whole interior is richly carved and gilded. The walls are covered with rare paintings. Standing close beside the cathedral is the highly ornamented façade of a smaller church called El Sagrario Metropolitano. The city has about sixty church edifices, including La Profesa, Loreto, Santa Teresa, Santo Domingo and San Hipólito. At the time of the secularization of Church properties there were about 120 religious edifices in the city—churches, convents, monasteries, &c.—many of which were turned over to secular uses.

The national palace, also on the Plaza Mayor, has a frontage of 675 ft. on the east of the Plaza, and covers a square of 47, 840 sq. yds., or nearly 10 acres. It contains the executive offices of the government and those of five cabinet ministers (interior, foreign affairs, treasury, war and justice), the senate chamber, the general archives, national museum, observatory and meteorological bureau. The palace occupies the site of the residence of Moctezuma, which was destroyed by the Spaniards, and that of Hernando Cortés, which was also destroyed in 1692. It has three entrances on the Plaza, and over its main gateway hangs the "liberty bell" of Mexico, first rung by the humble parish priest Hidalgo, on the night of the 16th of September 1810, to call the people of Dolores to arms, and now rung at midnight on each recurring anniversary by the president himself. The national museum, which occupies the east side of the national palace, is rich in Mexican antiquities, among which are the famous "calendar stone,"[1] supposed to be of Toltec origin, and the "sacrificial stone" found in the ruins of the great *teocalli* destroyed by Cortés. Near the cathedral is the *monte de piedad*, or government pawnshop, endowed in 1775 by Pedro Romero de Terreros (conde de Regla) with £75,000, and at one time carrying on a regular banking business including the issue of bank-notes. Its business is now limited to the issue of small loans on personal property—the aggregate sometimes reaching nearly £50,000 a month. The national library, which has upwards of 225,000 volumes, occupies the old St Augustine Church, dedicated in 1692 and devoted to its present use by Juárez in 1867. It contains an interesting collection of the busts of Mexican celebrities. The academy of San Carlos and school of fine arts (founded in 1778) likewise contains good collections of paintings and statuary.

Among other institutions are the new post office, begun in 1902 and finished in 1907; the Minería, occupied by the schools of mining and engineering; the military school, occupying a part of the castle of Chapultepec; the Iturbide palace, now occupied as a hotel; the Iturbide theatre, occupied by the chamber of deputies, for which a new legislative palace to cost 2,500,000 pesos was under construction in 1909; the new palace of justice; the old mint, dating from 1537; the new penitentiary, completed in 1900; the Pantéon, with its monuments to the most celebrated Mexicans; the new general hospital; the jockey club on Plaza Guardiola, a new university (1910) and new school edifices of modern design. The city is likewise generously provided with hospitals and asylums.

The old Spanish edifices were very solidly constructed of stone, and private residences were provided with iron gates and window guards strong enough to withstand an ordinary assault. Private houses were also provided with flat roofs (*azoteas*) and battlements, which gave them great defensive strength, as well as a cool, secluded retreat for their inmates in the evening. The old Moorish style of building about an open court, or *patio*, prevails, and the living-rooms of the family are on the second floor. The better residences of the old style were commonly of two storeys—the ground-floor being occupied by shops, offices, stables and servants' quarters. The more modern constructions of the Colonia Juárez and other new residence districts are more attractive and pretentious in appearance, but are less solidly built.

---

[1] Bandelier thinks it should be called the "Stone of the Sun."

Mexico was formerly one of the worst drained large cities of the New World, its subsoil being permanently saturated and its artificial drainage being through open ditches into the San Lazaro Canal which nominally discharged into Lake Texcoco. The difference in level between the city and the lake being less than six feet and the lake having no natural outlet, typhus fever became a common epidemic in its lower and poorer sections. The earliest effort to correct this evil was by the Dutch engineer Maartens (Span., Martinez), who planned a deep cutting through Nochistongo Hill, north of the city, to carry away the overflow of Lake Zumpango (7493 ft. elevation) to the river Tula, a tributary of the Panuco. The cutting was 13 m. long and is known as the Tajo de Nochistongo. It was begun in 1607—a year when the city was completely flooded—but was not completed until 1789, and then it was found that the city was still subject to partial inundations, although an enormous sum of money and 70,000 lives of Indian labourers had been expended upon it. The worst inundation in the history of the city occurred in 1629, when its streets were covered to a depth of 3 ft. and remained flooded until 1634. In 1856 President Ignacio Comonfort invited tenders for drainage works conditional on the use of waste waters for irrigation purposes, and the plan executed consists of a canal and tunnel 43 m. long, starting from the east side and 4¼ ft. below the mean level of the city and running north to Zumpango and thence eastward into a tunnel over 6 m. long, which discharges into a small tributary of the Panuco river near the village of Tequixquiac. The greatest depth of the tunnel is 308 ft. below the surface. The works were inaugurated in 1900.

For the water supply the Aztecs used the main causeway through their city as a dam to separate the fresh water from the hills from the brackish water of Texcoco, and obtained drinking water from a spring at the base of the hill of Chapultepec. The Spaniards added three other springs to the supply and constructed two long aqueducts to bring it into the city. Three other sources were added during the 19th century, and in 1899–1900 steps were taken to secure a further supply from the Rio Hondo. Besides these there are 11 public and 1375 private artesian wells in the city. All these sources are estimated to yield about 220 to 230 litres per head.

Considerable attention has always been given to education in Mexico, but in colonial times it was limited in scope, and to the dominant classes. The old university of Mexico, with its faculties of theology, law and medicine (founded 1551 and inaugurated 1553), ceased to exist in 1865 and was succeeded by schools of engineering, law and medicine, which have been signally successful. The government also maintains schools of agriculture, commerce, fine arts, music, pharmacy, technology, and an admirable preparatory or high school, besides a large number of primary and secondary schools for which modern school buildings have been erected. Normal and industrial schools for both sexes are maintained, the latter (*artes y oficios*) performing a very important service for the poorer classes. In 1908 there were 353 government schools in the city, including 13 professional and technical schools, and nearly 200 private schools. There are also several scientific organizations and societies. The Mexican Geographical Society (*Sociedad mexicana de geografía y estadística*), founded in 1833, has rendered invaluable services in the work of exploration and publication; there are also the Geological Society, the Association of Engineers and Architects, and the Society of Natural History.

Through lack of water-power and cheap fuel Mexico has never been rated as a manufacturing city. However, the development of electric power, and the possibility of transmitting it for long distances, have worked a noteworthy change in this respect, and a large number of industries have been added in recent years. The largest of these electric-power plants is on the Necaxa and Tenango rivers, in the state of Puebla, 92 m. from the city, which is designed to furnish 40,000 horse-power for industrial and lighting purposes, and a duplicate plant was decided upon in 1904. Another plant is in the suburb of San Lazaro, the current being distributed by over 100 m. of underground mains in the city and many miles of overhead wires in its outskirts and suburbs. Other plants are at San Ildefonso, 12 m. distant, and on the Churubusco river, 16 m. south. According to a British consular report for 1904 there were 153 manufacturing establishments in the city producing cotton, linen and silk textiles, leather, boots and shoes, alcohol and alcoholic beverages, beer, flour, conserves and candied fruits, cigars and cigarettes, Italian pastes, chocolate, starch, hats, oils, ice, furniture, pianos and other musical instruments, matches, beds, candles, chemicals, iron and steel, printing-type, paint and varnish, glass, looking-glass, cement and artificial stone, earthenware, bricks and tiles, soap, cardboard, papier mâché, cartridges and explosives, white lead, perfumery, carriages and wagons, and corks. To these should be added the foundries and iron-working shops which add so much to the prosperity of modern Mexico. Perhaps the most important of these manufactories are the cotton mills, of which there are 13, and the cigar and cigarette factories, of which there are 10. In the suburbs, oils, chemicals, cigarettes and bricks are made at Tacuba; cotton textiles at Contreras, San Angel and Tlalpam; paper and boots at Tacubaya, and bricks at Mixcoac and Coyoacan. A little farther away are the woollen mills of San Ildefonso, the paper-mills of San Rafael, and important works for the manufacture of railway rolling stock.

The railway connexions include direct communication with one port on the Gulf coast and with two on the Pacific—lines were under construction in 1909 to two other Pacific ports—and indirect communication with two on the Gulf. The Mexican and Interoceanic lines connect with Vera Cruz, the Mexican Central with Manzanillo, via Guadalajara and Colima, and the Vera Cruz & Pacific (from Cordoba) with the Tehuantepec line and the port of Salina Cruz. The last-mentioned line also gives indirect connexion with the port of Coatzacoalcos, and the Mexican Central, via San Luis Potosí, with Tampico. A southern extension of the Mexican Central, via Cuernavaca, has reached the Balsas river and will be extended to Acapulco, once the chief Pacific port of Mexico and the dépôt for the rich Philippine trade. A Mexican extension of the (American) Southern Pacific which has been completed from Nogales to Mazatlán is to be extended to Guadalajara, which will give the national capital direct communication with the thriving ports of Mazatlán and Guaymas. In addition to these, the Mexican Central and Mexican National, now consolidated, give communicaton with the northern capitals and the United States, and the Mexican Southern runs southward, via Puebla, to the city of Oaxaca. These railways, with the shorter lines radiating from the city, connect it with nearly all the state capitals and principal ports.

The population by the census of 1900 was 344,721—an increase of 14,947 over the returns of 1895. The great majority of the inhabitants is composed of Indians and half-breeds, from whom come the factory workers, labourers, servants, porters and other menial wage-earners. In former times Mexico was overrun with mendicants (*pordioseros*), vagrants and criminals (*rateros*), and the "Portales de las Flores" on the east of the Plaza Mayor was a favourite "hunting-ground" for them because of its proximity to the cathedral; but modern conditions have largely reduced this evil. The foreign population includes many capitalists and industrial managers who are doing much to develop the country, the American colony being concentrated in a fine modern residential district on the south-western side of the city.

History.—The City of Mexico dates, traditionally, from the year 1325 or 1327, when the Aztecs settled on an island in Lake Texcoco. The Aztec name of the city was Tenochtitlán, derived either from Tenoch, one of their priests and leaders, or from *tenuch*, the Indian name for the "nopal," which is associated with its foundation. The modern name is derived from Mexitli, one of the names of the Aztec god of war Huitzilopochtli, which name was later on applied also to the Aztecs themselves. The island settlement, which was practically a lake-village built on islets—some of them undoubtedly artificial, and perched on stakes—grew rapidly with the increasing power and civilization of its inhabitants, who had the remains of an earlier civilization (Tula, Teotihuacán, Cholula, and other older towns) to assist in their development. About the middle of the 15th century their mud-and-rush dwellings were partly replaced by stone structures, grouped around the central enclosure of the great *teocalli*, and bordering the causeways leading to the mainland. The town had reached its highest development when the Spaniards appeared in 1519, when it is said to have had, including suburban towns, a total of 60,000 dwellings, representing about 300,000 inhabitants. It was at that time about 12 m. in circumference, everywhere intersected by canals, and connected with the mainland by six long and solidly constructed causeways, as shown in the plan given in the edition of Cortés's letters published at Nuremberg in 1524 (reproduced in vol. i. of H. H. Bancroft's *History of Mexico*, San Francisco, 1883, p. 280). Allowance should be made for the habit of exaggeration among the Spanish adventurers of that time, and also for the diplomacy of Cortés in magnifying his exploits to win the favour of his king. The truth is, without doubt, that the dwellings of the lower classes were still built of reeds and mud, and covered the greater part of the city's area, otherwise it is impossible to understand how a mere handful of Spanish soldiers, without tools and explosives, could so easily have levelled it to the ground. After its almost total destruction in November 1521, Cortés employed some 400,000 natives in rebuilding the city on its former site. Since then the lake has decreased greatly in extent, its area being reduced to 11½ sq. m. and its shore-line being more than 3 m. distant from the city it once surrounded. During Spanish rule the only break in the ordinary course of events was the revolt of 1692, which resulted in the destruction of the municipal buildings. The city was not much disturbed by the struggle for independence, but it was afterwards the scene of many a revolution until the dictatorial authority of Porfirio Diaz put an end to petty pronunciamentos and partisan intrigues.

In the war between Mexico and the United States the most decisive campaign was that of General Winfield Scott directed against the Mexican capital. With the advanced guard of an army of about 10,000 men he arrived on the 10th of August 1847 at Ayolta, on the national road 16 m. south-east of the city; but as the approaches from this direction were very strongly fortified he cut a new road southward along the eastern shore of Lake Chalco and westward along the southern shore of lakes Chalco and Xochimilco to San Augustin, where his army arrived on the 17th and 18th of August. The city was now 10 m. distant by a direct road to the northward, but as the village of San Antonio, only 3 m. ahead, was strongly fortified, another short detour was made to the westward by cutting a road through a field of broken lava. This movement brought the Americans to the hill of Contreras, which was held by General Valencia with a force of some 7000 and 22 pieces of artillery, while President Santa Anna was in the neighbourhood with reinforcements numbering 12,000 or more. The Mexicans were routed on the morning of the 20th of August after suffering heavy losses. San Antonio was easily taken about noon of the same day, and in the afternoon the main division of the Mexican army was driven from the stone church and intrenchments at Churubusco. Three days later General Scott agreed to an armistice, but Mexico rejected the terms of peace, and hostilities were resumed on the 7th of September. During the armistice the American troops were quartered in and about the village of Tacubaya, about 2½ m. west by south of the city. Near Tacubaya, on the north by west, were some massive stone buildings known as El Molino del Rey, or the King's Mill. When attacked by the Americans under the immediate command of General W. J. Worth in the early morning of the 8th of September these buildings were defended by more than 10,000 Mexicans under Generals Leon, Alvarez and Perez, and they were captured only after a most desperate fight, which cost the Americans 787 killed and wounded and the Mexicans at least 2000 killed, wounded, and prisoners. To enter the city by way of the Tacubaya causeway it was still necessary for the Americans to capture Chapultepec. This hill, defended by about 4000 Mexicans under General Nicolas Bravo, was bombarded on the 12th of September, and was carried by assault on the 13th. On the following day the City of Mexico surrendered. It was then occupied by the American army under General Winfield Scott, and held by them until the signing of the treaty of Guadalupe-Hidalgo (May 1848).

The French intervention of 1861 led to a second occupation by a foreign power—a French military force under General Forey taking possession in June 1863. Maximilian, archduke of Austria, was crowned emperor of Mexico in the cathedral in June 1864, and held possession of the capital until the 21st of June 1867, when it was captured by General Porfirio Diaz. Earthquake shocks are of frequent occurrence, but the city rarely suffers any material damage. The great earthquake shocks of the 30th and 31st of July 1909, however, caused considerable damage in the city, and a few lives were lost.

For further description see H. H. Bancroft, *History of Mexico* (6 vols., San Francisco, 1883); Robert S. Barrett, *Standard Guide to the City of Mexico and Vicinity* (Mexico, 1900); Thomas A. Janvier, *The Mexican Guide* (5th ed., New York, 1890); D. Charnay, *Ancient Cities of the New World* (Eng. ver., New York, 1887); and the *Plano de la ciudad de México*, in the *Diccionario enciclopédico hispano-americano* (Barcelona, 1893), xii. 740.

MEXICO, FEDERAL DISTRICT OF, a territory set apart for the independent and exclusive use of the Mexican Federal Government, occupying the south-eastern part of the Valley of Mexico, and taken from and lying within the State of Mexico, which forms its boundaries on all sides except the south where it touches the state of Morelos. Pop. (1900), 540,478, largely Indian and half-breeds; area, 463 sq. m., or accordingly to later computation 1498¾ sq. kilom. (578⅝ sq. m.). The district is very irregular in outline, its greatest length (N.W. to S.E.) being 30 m., and its greatest breadth 25 m. It was formerly divided into one urban municipality and four rural prefectures, but under the law of the 26th of March 1903 it is divided into 13 municipalities, Mexico, Guadalupe-Hidalgo, Atzcapotzalco, Tacuba, Tacubaya, Mixcoac, Cuajimalpa, San Angel, Coyoacan, Tlalpám, Xochimilco, Milpa Alta and Ixtapalapa; the first of these comprises the national capital and its immediate suburbs, and the other 12 the unequal divisions of the district with a considerable number of towns and villages. Indians and half-breeds form more than one-half of the rural population engaged in agriculture and gardening, beside which there is a large percentage employed in manufacturing industries. The government of the district is exercised by the national executive in accordance with the organic law of 1903, though some measure of popular government is vested in municipal councils (*ayuntamientos*) elected by popular vote for terms of four years. These councils have lost much of their original legislative character, but they must be consulted in matters of local importance, such as water supply, sanitary works, and the exploitation or sale of municipal property, and in regard to all contracts affecting the municipality. They can veto by a two-thirds vote the execution of any contract or administrative project, which then, at the end of four months, if again vetoed must be taken before the President of the Republic for adjudication. The administrative officers, who are appointed by the national executive, consist of a governor of the federal district, the director-general of public works, and the president of the superior board of health. The three form a superior council of district government which exercises a supervisory and advisory power, "revising, confirming, reforming or revoking the acts of each one of the members of the council, whenever these acts are called in question." The council also exercises a general supervision of the making of contracts. The governor represents the national government, and has special charge of the fire and police departments, prisons, imposition of penalties for violation of ordinances, public diversions and festivities, civil registry, street traffic, inspection of weights and measures, and the sale of intoxicating liquors. The director-general of public works has special charge of the water supply, streets and roads, parks, monuments, public lighting, drainage, street cleaning, public buildings not under federal control, cemeteries, slaughter-houses and markets, building operations, and all municipal or communal property. The president of the superior board of health has charge of all sanitary works, general sanitary inspection, the sanitary administration of markets, slaughter-houses and cemeteries, and the introduction of meats from other localities. The government of the district is copied, in part, from that of the District of Columbia in the United States, but its citizens are not disfranchised. They elect the *ayuntamientos*, which exercise no slight influence in local affairs, and, like any state, elect senators and deputies to the National Congress.

The principal towns of the district, some of which are merely suburbs of the capital, are Guadalupe, Tacubaya, Tlalpám and Xochimilco. Within the municipal limits of Mexico City are Chapultepec, Santa Anita and the hot springs of El Peñón, which are popular suburban resorts easily reached by the ordinary urban tramway service. Chapultepec (Grasshopper Hill) is an isolated rock nearly 200 ft. high surrounded by a beautiful park and surmounted by a fortified structure called the "Castle," containing the summer residence of the president and the national military school. A finely graded road leads to the summit. The park contains a grove of old cypress trees (*Taxodium distichum*, called "ahuehuetes" by the natives), one of which is 45 ft. in circumference and nearly 200 ft. high. The hill is nearly 3 m. south-west of the city and once commanded one of its principal causeway approaches. It was assaulted and captured by the American forces under General Winfield Scott on the 13th of September 1847, after a stubborn resistance. A monument to the cadets of the military school who died in this battle stands in the park. The castle, which was built by the viceroys, was greatly embellished by the emperor Maximilian, who planned for it the drive known as the Paseo de la Reforma. Of the neighbouring towns Guadalupe or Guadalupe-Hidalgo (pop. 5834 in 1900), 2½ m. north by east from Mexico City, near the shore of Lake Texcoco, is chiefly known for its shrine to Our Lady of Guadalupe, who is said to have appeared there to the Indian Juan Diego in 1531. The shrine stands on the principal plaza and is visited by many thousands of pilgrims during the year, whose pious contributions have so enriched the church that its sacred vessels, altar-rails, candelabra and other accessories are estimated to contain fifty tons of silver. The treaty of peace between Mexico and the United States was signed here on the 2nd of February 1848. Tacubaya (pop. 18,342 in 1900), on the lower slopes of the Montes de las Cruces, about 5 m. west-south-west of the city, with which it is connected by rail, is noted for its fine old residences and beautiful gardens. The National Astronomical Observatory occupies a fine modern edifice. At Popotla is an aged tree under which, according to tradition, Cortés sat and wept after his terrible retreat from the Aztec capital on the *noche triste*. Farther south on the lowest slopes of the mountain range are San Angel and Tlalpam, the latter (pop. 4732 in 1900) standing partly on the plain 12 m. south by west of the capital. In both much attention is given to floriculture, and both are favourite country residences of the richer citizens. Xochimilco (field of flowers), (pop. 10,712 in 1900) on the west shore of the lake of that name and 10 m. south by east of the city, is an Indian town dating long before the discovery of America. It lies in the midst of a fertile plain devoted to the production of fruit, vegetables and flowers for the city markets. Its gardens are carried out on the shallow lake by floating masses of water-plants covered with soil and secured by poplar stakes, which, taking root, soon surround them with living boundaries. These remarkable and productive gardens, called *chinampas*, have so increased in number and extent that the lake is practically covered by them, with the exception of the waterways, which are kept open by scooping up mud from the bottom. From the lake a broad canal runs northward to the eastern suburbs of the city. It is known as the Viga, and is believed to have been opened by the Aztecs for the transportation of garden produce to their island capital.

MEXICO, GULF OF, a mediterranean gulf almost surrounded by the coasts of the United States and Mexico, and forming the northern division of the extension westward of the west Atlantic trench (see ATLANTIC OCEAN). Its southern boundary is defined by the partly submerged ridge which extends eastwards from the peninsula of Yucatán, and on which the island of Cuba is situated: to the east it communicates directly with the Atlantic by the Strait of Florida. On the western side of Yucatán a southerly embayment is formed by the Gulf of Campeachy. The United States coast closely follows the parallel of 30° N., while the parallel of 20° N. cuts across the Gulf of Campeachy: the greatest length—Vera Cruz to Florida—is 1120 m., and greatest width—Galveston to Campeachy—680 m. The total area is approximately 716,000 sq. m.

The deepest part of the Gulf of Mexico, the so-called "Sigsbee" deep, lies below the line of 2000 fathoms, between 23° and $25\frac{1}{2}$° N., and $84\frac{1}{2}$° to 95° W. It is widest to the west, where the breadth is about 120 m., and narrows to 25 m. at its greatest depth (2119 fathoms) between 86° and 88° W., widening again to some 80 m. farther eastward. The continental shelf is for the most part narrow: its breadth is 6 m. at Cape Florida, 120 m. along the west coast of Florida, 10 m. at the south pass of the Mississippi, 130 m. near the boundary of Texas and Louisiana, and 15 m. off Vera Cruz. The shores are low, sandy and marshy, the coast-line being frequently doubled by lagoons. There are no islands except the "Keys" of Florida and Yucatán, and Cuba. The tides in the Gulf of Mexico are of comparatively small range (springs rarely exceed 4 ft. and neaps $2\frac{1}{2}$ ft.), but a remarkable feature is the exaggeration of the diurnal inequality to such an extent as almost to extinguish the semi-diurnal tide in the inner parts of the gulf, giving high and low water only once daily. The mean level of the water in the Gulf of Mexico was formerly given as about 40 in. above that of mean sea-level at New York, but later reports on precise levellings from New York to Biloxi through St Louis describe it vaguely as "somewhat higher." The current movement in the Gulf of Mexico consists of a rotational movement in the direction of the hands of a watch, the branch of the equatorial current which enters the Caribbean Sea passing into the Gulf by the Strait of Yucatán and issuing from it by the Strait of Florida as the Gulf Stream, which unites with the remainder of the northward moving water, forming the Antilles current.

From March to September the prevailing winds are the north-east trades; these undergo considerable modification on account of the configuration of the surrounding land, and the rains which accompany them are interrupted by spells of calm thick weather, and rarely by northerly winds known as *Nortes del hueso colorado* and *Chocolateros*. In the colder dry season, from October to April, the climatic situation is dominated by the relatively high temperature of the surface of the gulf, causing a cyclonic inflow of air which is associated with the strong northerly winds or "northers" prevailing on the western side, more particularly along the Mexican coast. The northers sometimes blow with terrific force and are at times accompanied by rain. The form and position of the Gulf of Mexico exercise a profound influence on the climate of the whole of the southern and south-eastern states of the Union, and indeed of the greater part of North America. (H. N. D.)

MEYER, CHRISTIAN ERICH HERMANN VON (1801–1869), German palaeontologist, was born at Frankfort-on-the-Main, on the 3rd of September 1801. In 1832 he issued a work entitled *Palaeologica*, and in course of time he published a series of memoirs on various fossil organic remains: mollusca, crustacea, fishes and higher vertebrata. His more elaborate researches were those on the Carboniferous amphibia, the Permian reptiles, the Triassic amphibia and reptiles, and the reptiles of the Lithographic slates; and the results were embodied in his great work *Zur Fauna der Vorwelt* (1845–1860), profusely illustrated with plates drawn on stone by the author. He was associated with W. Dunker and K. A. Zittel in the publication of the *Palaeontographica*, which began in 1851. He was awarded the Wollaston medal by the Geological Society of London in 1858. He died on the 2nd of April 1869.

MEYER, HEINRICH AUGUST WILHELM (1800–1873), German Protestant divine, was born at Gotha on the 10th of January 1800. He studied theology at Jena, and eventually became (1841) pastor, member of the consistory, and superintendent at Hanover. He died on the 21st of June 1873. He is chiefly noted for his valuable *Kritischexegetischer Kommentar zum Neuen Testament* (16 vols.), which began to appear in 1832, was completed in 1859 with the assistance of J. E. Huther, Friedrich Düsterdieck and G. K. G. Lünemann, and has been translated into English. New editions have been undertaken by such scholars as A. B. Ritschl, B. Weiss, H. Wendt, K. F. G. Heinrici, W. Beyschlag and F. A. E. Sieffert.

Meyer also published an edition of the New Testament, with a translation (1829) and a Latin version of the symbolical books of the Lutheran Church (1830).

He is not to be confounded with JOHANN FRIEDRICH VON MEYER (1772–1849), the senator of Frankfort, who published a translation of the Bible in 1819 (*Die heilige Schrift in berichtigter Übersetzung mit kurzen Anmerkungen*; 2nd ed., 1823; 3rd ed., 1855).

MEYER, JULIUS LOTHAR (1830–1895), German chemist, was born on the 19th of August 1830, at Varel in Oldenburg. He was the son of a physician, and went to study medicine first at Zürich University in 1851, and then, two years later, at Würzburg, where he had R. Virchow as his teacher in pathology. The influence of C. F. W. Ludwig, under whom he studied at Zürich, decided him to devote his attention to physiological chemistry, and therefore he went, after his graduation (1854), to Heidelberg, where R. Bunsen held the chair of chemistry. There he was so influenced by G. R. Kirchhoff's mathematical teaching that he took up the study of mathematical physics at Königsberg under F. E. Neumann. In 1859 he became privat-docent in physics and chemistry at Breslau, where in the preceding year he had graduated as Ph. D. with a thesis on the action of carbon monoxide on the blood. In 1866 he accepted a post in the School of Forestry at Neustadt-Eberswalde, but soon moved to Carlsruhe Polytechnic. During the Franco-German campaign the Polytechnic was used as a hospital, and he took an active part in the care of the wounded. Finally, in 1876, he became professor of chemistry at Tübingen, where he died on the 11th of April 1895. His name is best known for the share he had in the periodic classification of the elements. He noted, as did J. A. R. Newlands in England, that if they are arranged in the order of their atomic weights they fall into groups in which similar chemical and physical properties are repeated at periodic intervals; and in particular he showed that if the atomic weights are plotted as ordinates and the atomic volumes as abscissae, the curve obtained presents a series of maxima and minima, the most electro-positive elements appearing at the peaks of the curve in the order of their atomic weights. His book on *Die modernen Theorien der Chemie*, which was first published in Breslau in 1864, contains a discussion of relations between the atomic weights and the properties of the elements. In 1882 he received from the Royal Society, at the same time as D. J. Mendeléeff, the Davy medal in recognition of his work on the Periodic Law. A younger brother, O. E. Meyer, became professor of physics at Breslau in 1864.

MEYER, KONRAD FERDINAND (1825–1898), Swiss poet and novelist, was born at Zürich on the 11th of October 1825. After studying law at the university, he went for considerable periods to Lausanne, Geneva and Paris, and in Italy interested himself in historical research. In 1875 he settled at Kilchberg near Zürich, was created in 1880 a doctor philosophiae *honoris causa* by that university, and died at Kilchberg on the 28th of November 1898. After Gottfried Keller, Konrad Meyer is the most important Swiss poet of modern times, though as a novelist he was perhaps more successful. His poetical works include *Balladen* (1867); *Romanzen und Bilder* (1870); the epic poem, *Huttens letzte Tage* (1871); and *Gedichte* (1882; 20th ed., 1901). Among his novels must be specially mentioned *Jürg Jenatsch* (1876; 20th ed., 1894); *Der Schuss von der Kanzel* (1878); *Der Heilige* (1880; 12th ed., 1894; English by M. von Wendheim, *Thomas à Becket, the Saint*, 1885); *Die Richterin* (1885); *Die Versuchung des Pescara* (1887); *Angela Borgia* (1891). His shorter stories were collected in two volumes in 1885 (5th ed., 1892).

See A. Reitler, *Konrad Ferdinand Meyer* (1885); Lina Frey, *K. F. Meyer's Gedichte und Novellen* (1892); K. E. Kranzos, *K. F. Meyer* (1899); A. Frey, *K. F. Meyer* (1900); H. Kraeger, *K. F. Meyer: Quellen und Wandlungen seiner Gedichte* (1901); B. Meyer, *K. F. Meyer in der Erinnerung seiner Schwester* (1904); *Briefwechsel zwischen Luise von François und K. F. Meyer*, herausg. von A. Bettelheim (1905); A. Langmesser, *K. F. Meyer* (1905).

MEYER, [MARIE] PAUL HYACINTHE (1840–   ), French philologist, was born in Paris on the 17th of January 1840. He was educated at the École des Chartes, and in 1863 was attached to the manuscript department of the Bibliothèque Nationale. In 1876 he became professor of the languages and literatures of southern Europe at the Collège de France. In 1882 he was made director of the École des Chartes, and a year later was nominated a member of the Academy of Inscriptions. He was one of the founders of the *Revue critique*, and a founder and the chief contributor to *Romania* (1872). Paul Meyer began with the study of old Provençal literature, but subsequently did valuable work in many different departments of romance literature, and ranks as the chief modern authority on the French language. He is the author of *Rapports sur les documents manuscrits de l'ancienne littérature de la France conservés dans les bibliothèques de la Grande Bretagne* (1871); *Recueil d'anciens textes bas-latins, provençaux et français* (2 parts, 1874–1876); *Alexandre le Grand dans la littérature française du moyen âge* (2 vols., 1886). He edited a great number of old French texts for the *Société des anciens textes français*, the *Société de l'histoire de France* and independently. Among these may be mentioned *Aye d'Avignon* (1861), with Guessard; *Flamença* (1865); the *Histoire* of Guillaume le Maréchal (3 vols., 1892–1902); *Raoul de Cambrai* (1882), with A. Longnon; *Fragments d'une vie da Saint Thomas de Cantorbéry* (1885); *Guillaume de la Barre* (1894).

MEYER, VICTOR (1848–1897), German chemist, was born at Berlin on the 8th of September 1848, and studied at Heidelberg University under R. W. Bunsen, H. F. M. Kopp, G. R. Kirchhoff and H. L. F. Helmholtz. At the age of twenty he entered J. F. W. A. Baeyer's laboratory at Berlin, attacking among other problems that of the composition of camphor. In 1871, on Baeyer's recommendation, he was engaged by H. von Fehling as his assistant at Stuttgart Polytechnic, but within a year he left to succeed J. Wislicenus at Zürich. There he remained for thirteen years, and it was during this period that he devised his well-known method for determining vapour densities, and carried out his experiments on the dissociation of the halogens. In 1882, on the death of W. Weith (1844–1881), professor of chemistry at Zürich University, he undertook to continue the lectures on benzene derivatives, and this led him to the discovery of thiophen. In 1885 he was chosen to succeed Hans Hübner (1837–1884) in the professorship of chemistry at Göttingen, where stereochemical questions especially engaged his attention; and in 1889, on the resignation of his old master, Bunsen, he was appointed to the chair of chemistry in Heidelberg. He died on the 8th of August 1897. In recognition of his brilliant experimental powers, and his numerous contributions to chemical science, he was awarded the Davy medal by the Royal Society in 1891.

MEYERBEER, GIACOMO (1791–1863), German composer, first known as Jakob Meyer Beer, was born at Berlin on the 5th of September 1791,[1] of a wealthy and talented Jewish family. His father, Herz Beer, was a banker; his mother, Amalie (*née* Wulf), was a woman of high intellectual culture; and two of his brothers distinguished themselves in astronomy and literature. He studied the pianoforte, first under Lauska, and afterwards under Lauska's master, Clementi. When seven years old he played Mozart's Concerto in D Minor in public, and at nine he was pronounced the best pianist in Berlin. For composition he was placed under Zelter, and then under Bernard Weber, director of the Berlin opera, by whom he was introduced to the Abbé Vogler. Vogler invited him to Darmstadt, and in 1810 received him into his house, where he formed an intimate friendship with Karl Maria von Weber, who also took daily lessons in counterpoint, fugue and extempore organ-playing. At the end of two years the grand duke appointed Meyerbeer composer to the court. His first opera, *Jephtha's Gelübde*, failed lamentably at Darmstadt in 1811, and his second, *Wirth und Gast* (*Alimelek*), at Vienna in 1814. These checks discouraged him so cruelly that he feared he had mistaken his vocation. Nevertheless, by advice of Salieri he determined to study vocalization in Italy, and then to form a new style. But at Venice he was so captivated by Rossini that, renouncing all thought of originality, he produced a succession of seven Italian operas—*Romilda e Costanza*, *Semiramide riconosciuta*, *Eduardo e Cristina*, *Emma di Resburgo*, *Margherita d'Anjou*, *L'Esule di Granata* and *Il Crociato in Egitto*—which all achieved a success as brilliant as it was unexpected. Against this act of treason to German art Weber protested most earnestly; and before long Meyerbeer himself grew tired of his defection. An invitation to Paris in 1826 led him to review his position dispassionately, and he came to the conclusion that he was wasting his powers. For several years he produced nothing in public; but, in concert with Scribe, he planned his first French opera, *Robert le Diable*. This gorgeous spectacle was produced at the Grand Opéra in 1831. It was the first of its race, a grand romantic opera, with situations more theatrically effective than any that had been attempted either by Cherubini or Rossini, and with ballet music such as had never yet been heard, even in Paris. Its popularity exceeded all expectations; yet for five years Meyerbeer appeared before the public no more.

His next opera, *Les Huguenots*, was first performed in 1836. In gorgeous colouring, rhetorical force, consistency of dramatic treatment, and careful accentuation of individual types, it is at least the equal of *Robert le Diable*. In two points only did its interest fall short of that inspired by the earlier work. Meyerbeer had shown himself so eminently successful in his treatment of the supernatural that one regretted the omission of that element; and, more important still, the fifth act proved to be an anti-climax. The true interest of the drama culminates at the close of the fourth act, when Raoul, leaping from the window to his death, leaves Valentine fainting upon the ground. The opera now usually ends at the fourth act.

After the production of *Les Huguenots* Meyerbeer spent many years in the preparation of his next greatest works—*L'Africaine* and *Le Prophète*. The libretti of both these operas were furnished by Scribe; and both were subjected to countless changes; in fact, the story of *L'Africaine* was more than once entirely rewritten.

---

[1] Or, according to some accounts, 1794.

Meanwhile Meyerbeer accepted the appointment of kapellmeister to the king of Prussia, and spent some years at Berlin, where he produced *Ein Feldlager in Schlesien*, a German opera, in which Jenny Lind made her first appearance in Prussia. Here also he composed, in 1846, the overture to his brother Michael's drama, *Struensee*. But his chief care at this period was bestowed upon the worthy presentation of the works of others. He began by producing his dead friend Weber's *Euryanthe*, with scrupulous attention to the composer's original idea. With equal unselfishness he procured the acceptance of *Rienzi* and *Der fliegende Holländer*, the first two operas of Richard Wagner, who, then languishing in poverty and exile, would, but for him, have found it impossible to obtain a hearing in Berlin. With Jenny Lind as prima donna and Meyerbeer as conductor, the opera flourished brilliantly in the Prussian capital; but the anxieties materially shortened the composer's life.

Meyerbeer produced *Le Prophète* at Paris in 1849. In 1854 he brought out *L'Étoile du nord* at the Opéra Comique, and in 1859 *Le Pardon de Ploërmel* (*Dinorah*). His last great work, *L'Africaine*, was in active preparation at the Académie when, on the 23rd of April 1863, he was seized with a sudden illness, and died on the 2nd of May. *L'Africaine* was produced with pious attention to the composer's minutest wishes, on the 28th of April 1865.

Meyerbeer's genius was criticized by contemporaries with widely different results. Mendelssohn thought his style exaggerated; Fétis thought him one of the most original geniuses of the age; Wagner ungratefully calls him "a miserable music-maker," and "a Jewish banker to whom it occurred to compose operas." The reality of his talent has been recognized throughout all Europe; and his name will live so long as intensity of passion and power of dramatic treatment are regarded as indispensable characteristics of dramatic music. But his work shows that these qualities, with the aid of an experienced stage-writer, may be entirely independent of genuine musical insight.

MEYNELL, ALICE CHRISTIANA (1850–), English poet and essayist, was the daughter of T. J. Thompson. Her early life was spent chiefly in Italy, and she was educated by her father. Her first volume of verse, *Preludes* (1875), illustrated by her sister Elizabeth, afterwards Lady Butler, attracted little public notice, but the delicacy and beauty of the poems and especially of the sonnet "Renunciation," were warmly praised by Ruskin. She married in 1877 the well-known Roman Catholic journalist and author Wilfrid Meynell, who became proprietor and editor of the *Weekly Register*. Under W. E. Henley's editorship she wrote regularly in prose for the *National Observer*, and also later for the *Pall Mall Gazette*, the *Saturday Review*, &c. Her *Poems* (1893), including much of the earlier volume of *Preludes*, brought her at last more definitely before the public; and this was followed in 1901 by another slender book of delicate verse, *Later Poems*. Mrs Meynell also showed herself a fine critic of poetry by her admirable selection, *The Flower of the Mind* (1897), an anthology of English verse. She edited the *Selected Poems* (1894) of T. G. Hake, the *Poetry of Pathos and Delight* (1896) of her intimate friend Coventry Patmore, and the selections from Patmore in the "Muses' Library." Her prose essays, remarkable for fineness of culture and peculiar restraint of style, appeared in successive volumes as *The Rhythm of Life* (1893), *The Colour of Life and other Essays* (1896), *The Children* (1897), and *The Spirit of Place* (1898). Later books are *London Impressions* (1898) and *The Work of John S. Sargent* (1903).

See W. Archer, *Poets of the Younger Generation* (1902).

MEYR, MELCHOIR (1810–1871), German poet, novelist and philosopher, was born at Ehringen on the 28th of June 1810, and died at Munich on the 22nd of April 1871. He read law and philosophy at Heidelberg and Munich. His greatest success was the *Erzählungen aus dem Ries* (4th ed. Leipzig, 1892), remarkable as an accurate and sympathetic picture of rural life and character. He wrote also tragedies (*Herzog Albrecht*, 1851; *Karl der Kühne*, 1862), novels (*Vier Deutsche*, 1861; *Ewige Liebe*, 1864), and, in later life, philosophical works with a strong religious tendency. Among these were *Emilie* (philosophical dialogues, 1863), *Die Religion des Geistes* (1871), *Die Fortdauer nach dem Tode* (1869), *Die Religion und ihre jetzt gebotene Fortbildung* (1871), and *Gedanken über Kunst, Religion und Philosophie* (1874). In these works he attempted to develop a Deistic system of philosophy. He was the author of an anonymous work entitled *Gespräche mit einem Grobian* (1866).

See *Melchior Meyr. Biographisches, Briefe und Gedichte*, edited by Graf Bothmer and M. Carrière (Leipzig, 1874).

MEYRIFAB, a small semi-nomad tribe of Africans of Semitic stock, settled on the east bank of the Nile near Berber. Contrary to Arab custom, it is said they never marry slaves.

MÉZERAY, FRANÇOIS EUDES DE (1610–1683), French historian, was born at Rye near Argentan, where his father was a surgeon. He had two brothers, one of whom, Jean Eudes, was the founder of the order of the Eudists. François studied at the university of Caen, and completed his education at the college of Ste Barbe at Paris. His *Histoire de France depuis Faramond jusqu' à Louis le Juste* (3 vols., 1643–1651), is a fairly accurate summary of French and Latin chronicles. Mézeray was appointed historiographer of France, and in 1649, on the death of Vincent Voiture, was admitted to the Académie Française. His *Abrégé chronologique* (3 vols., 1667–1668) went through fifteen editions between 1668 and 1717; but he did not hesitate in this work to attack the financiers, with the result that his salary as historiographer was diminished by Colbert. Mézeray succeeded Conrart as permanent secretary to the Académie Française (1675), and died at Paris on the 10th of July 1683. He translated Grotius's *Traité de la religion chrétienne* (1640), and a *Histoire des Turcs depuis 1612 jusqu'en 1649* (1650), which is an addition to a continuation of Chalcondyles.

See Daniel de Larroque, *Vie de François Eudes de Mézeray* (1720); vol. xiii. of *Causeries du lundi* by Sainte-Beuve, and Levavasseur's *Notice sur les trois frères: Jean Eudes, François Eudes, et Charles Eudes* (1855).

MÉZIÈRES, PHILIPPE DE (*c.* 1327–1405), French soldier and author, was born at the château of Mézières in Picardy. He belonged to the poorer nobility, and first served under Lucchino Visconti in Lombardy, but within a year he entered the service of Andrew, king of Naples, who was assassinated in September 1345. In the autumn of that year he set out for the East in the French army. After the battle of Smyrna in 1346 he was made a knight, and when the French army was disbanded he made his way to Jerusalem. He realized the advantage which the discipline of the Saracens gave them over the disorderly armies of the West, and conceived the idea of a new order of knighthood, but his efforts proved fruitless. The first sketch of the order was drawn up by him in his *Nova religio passionis* (1367–1368; revised and enlarged in 1386 and 1396). From Jerusalem he found his way in 1347 to Cyprus to the court of Hugo IV., where he found a kindred enthusiast in the king's son, Peter of Lusignan, then count of Tripoli; but he soon left Cyprus, and had resumed his career as a soldier of fortune when the accession of Peter to the throne of Cyprus (Nov. 1358) and his recognition as king of Jerusalem induced Mézières to return to the island, probably in 1360, when he became chancellor. He came under the influence of the pious legate Peter Thomas (d. 1366), whose friend and biographer he was to be, and Thomas, who became patriarch of Constantinople in 1364, was one of the chief promoters of the crusade of 1365. In 1362 Peter of Cyprus, with the legate and Mézières, visited the princes of western Europe in quest of support for a new crusade, and when the king returned to the east he left Mézières and Thomas to represent his case at Avignon and in the cities of northern Italy. They preached the crusade throughout Germany, and later Mézières accompanied Peter to Alexandria. After the capture of this city he received the government of a third part of it and a promise for the creation of his order, but the Crusaders, satisfied by the immense booty, refused to continue the campaign. In June 1366 Mézières was sent to Venice, to Avignon and to the princes of western Europe, to obtain help against the Saracens, who now threatened the kingdom of Cyprus. His efforts were in vain; even Pope Urban V. advised peace with the sultan. Mézières remained for some time at Avignon, seeking recruits for his order, and writing his *Vita S. Petri Thomasii* (Antwerp, 1659), which is invaluable for the history of the Alexandrian expedition. The *Prefacio* and *Epistola*, which form the first draft of his work on the projected order of the Passion, were written at this time.

Mézières returned to Cyprus in 1368, but was still at Venice when Peter was assassinated at Nicosia at the beginning of 1369, and he remained there until 1372, when he went to the court of the new pope Gregory XI. at Avignon. He occupied himself with trying to establish in the west of Europe the feast of the Presentation of the Virgin, the office of which he translated from Greek into Latin. In 1373 he was in Paris, and he was thenceforward one of the trusted counsellors of Charles V., although this king had refused to be dragged into a crusade. He was tutor to his son, the future Charles VI., but after the death of Charles V. he was compelled, with the other counsellors of the late king, to go into retirement. He lived thenceforward in the convent of the Celestines in Paris, but nevertheless continued to exert an influence on public affairs, and to his close alliance with Louis of Orleans may be put down the calumnies with which the Burgundian historians covered his name. When Charles VI. freed himself from the domination of his uncles the power of Mézières increased. To this period of his life belong most of his writings. Two devotional treatises, the *Contemplatio horae mortis* and the *Soliloquium peccatoris*, belong to 1386–1387. In 1389 he wrote his *Songe du vieil pêlerin*, an elaborate allegorical voyage in which he described the customs of Europe and the near East, and advocated peace with England and the pursuit of the Crusade. His *Oratio tragedica*, largely autobiographical, was written with similar aims. In 1395 he addressed to Richard II. of England an *Épistre* pressing his marriage with Isabella of France. The Crusade of 1396 inspired Mézières with no enthusiasm. The disaster of Nicopolis on the 28th of September 1396 justified his fears and was the occasion of his last work, the *Épistre lamentable et consolatoire*, in which he put forward once more the principles of his order as a remedy against future disasters. Mézières died in Paris on the 29th of May 1405.

Some of his letters were printed in the *Revue historique* (vol. xlix.); the two *épistres* just mentioned in Kervyn de Lettenhove's edition of Froissart's *Chroniques* (vols. xv. and xvi.). The *Songe du vergier* or *Somnium viridarii*, written about 1376, is sometimes attributed to him, but without definite proofs.

See Antoine Becquet, *Gallicae coelestinorum congregationis monasteria, fundationes* . . . . . (1719); the Abbé Jean Lebeuf's *Mémoires* in the *Mémoires* of the Academy of Inscriptions, vols. xvi. and xvii. (1752 and 1753); J. Delaville le Roulx, *La France en Orient au xiv. siècle* (1886–1890); A. Molinier, *Manuel de bibliographie historique* vol. iv. (1904); and especially the researches of N. Jorga, published in the *Bibliothèque de l'école des hautes études* vol. 110 (Paris 1896); and the same writer's *Philippe de Mézières, et la croisade au xiv. siècle* (1896). Jorga gives a list of his works and of the MSS. in which they are preserved, and analyses many of them. On the *Songe du vergier*, see P. Paris, in *Mémoires* vol. xv. (1843) of the Academy of Inscriptions.

MÉZIÈRES, a town of northern France, capital of the department of Ardennes, 55 m. N.E. of Reims by the Eastern railway. Pop. (1906), town, 7007; commune, 9393. The town itself, the streets of which are narrow and irregular, is situated on the neck of a peninsula formed by a loop of the Meuse. The river separates it from its suburb of Arches and the town of Charleville on the north and from the suburb of Pierre on the south. Adjoining Pierre is Mohon (pop. 5874), with metallurgical works. The fortifications of Mézières, as well as the citadel still dominating the town on the east, were built under Vauban's direction, but were dismantled in 1885 and 1886. Immediately to the east of the citadel runs a canal, which provides river-traffic with a short cut across the isthmus. The parish church (16th cent.) contains inscriptions commemorating the raising of the siege of Mézières in 1521 and the marriage of Charles IX. with the daughter of the emperor Maximilian II. (1570). The north and south portals, the Renaissance tower at the west end, and the lofty vaultings, are worthy of remark. The church, which suffered severely in 1870–71, has since been restored. The prefecture and the hôtel de ville, which contains several interesting pictures relating to the history of the town, belong to the 18th century. Mézières is the seat of a prefect and of a court of assizes, and there are manufactures of bicycles, and iron and steel castings for motors, railway-carriages, &c.

Founded in the 9th century, Mézières was at first only a stronghold belonging to the bishops of Reims, which afterwards became the property of the counts of Rethel. The town was increased by successive immigrations of the people of Liége, flying first from the emperor Otto, and afterwards from Charles the Bold; and also by concessions from the counts of Rethel. Walls were built in the 13th century, and in 1521 it was defended against the Imperialists by the Chevalier Bayard, to whom a statue was erected in 1893. The anniversary of the deliverance is still observed yearly on the 27th of September. In 1815 the Germans were kept at bay for six weeks, and in 1871 the town only capitulated after a bombardment during which the greater part of it was destroyed.

MEZÖTÚR, a town of Hungary, in the county of Jász-Nagykun-Szolnok, 88 m. S.E. of Budapest by rail. Pop. (1900), 25,367. It possesses important potteries. Large herds of cattle are reared on the communal lands, which are productive also of wheat, rapeseed and maize. Several well-attended fairs are held here annually.

MEZZANINE (It. *mezzano*; Fr. *entresol*; Ger. *Zwischengeschoss*), in architecture, a storey of small height introduced between two lofty storeys, or sometimes employed to allow of the introduction of two storeys equal together in height to lofty rooms on the same floor.

MEZZOFANTI, GIUSEPPE CASPAR (1774–1849), Italian cardinal and linguist, was born on the 17th of September 1774, at Bologna, and educated there. He was ordained priest in 1797, and in the same year became professor of Arabic in the university, but shortly afterwards was deprived for refusing to take the oath of allegiance to the Cisalpine Republic. In 1803 he was appointed assistant librarian of the institute of Bologna, and soon afterwards was reinstated as professor of oriental languages and of Greek. The chair was suppressed by the viceroy in 1808, but again rehabilitated on the restoration of Pius VII. in 1814, and continued to be held by Mezzofanti until his removal from Bologna to Rome in 1831, as a member of the congregation *de propaganda fide*. In 1833 he succeeded Angelo Mai as chief keeper of the Vatican library, and in 1838 was made cardinal and director of studies in the Congregation. He died at Rome on the 15th of March 1849. His peculiar talent, comparable in many respects to that of the so-called "calculating boys," was not combined with any exceptional measure of intellectual power, and produced nothing of permanent value. It seems certain, however, that he spoke with considerable fluency, and in some cases even with attention to dialectic peculiarities, some fifty or sixty languages of the most widely separated families, besides having a less perfect acquaintance with many others.

See Russell, *Life of the Cardinal Mezzofanti* (London, 1857); A. Bellesheim, *Giuseppe Cardinal Mezzofanti* (Würzburg, 1880).

MEZZOTINT. During the 19th century two revolutions occurred in the British art of mezzotinto engraving—"la manière anglaise." The original defect of the method was the incapacity of the mezzotint "burr" on copper to yield as many fine impressions as other forms of engraving. To this defect was attributable the introduction, in 1823, of steel instead of the soft copper previously used—a change which, with the endeavour to avoid technical difficulties, led to the "mixed style," or combination of mezzotint with etching, and a general departure from the traditional form of the art, "pure mezzotint" on copper. The affinity of the method to painting in black and white which differentiates it from other kinds of engraving, and was the distinguishing charm of the mezzotints of the 17th and 18th centuries, was for a time lost, but a revival of pure mezzotint on copper, beginning in 1880—a return, in fact, to the mode in which the classics of the art were engraved in the time of Sir Joshua Reynolds—was made possible by the invention of steel-facing. By this process engraved copper plates are electroplated with a film of steel, renewable when worn in course of printing; and a mezzotint on copper, so protected, yields more fine impressions than if it had been engraved on steel, whilst the painter-like quality remains unimpaired.

In "pure mezzotint" the design is evolved from dark to light entirely by scraping away more or less of the previously laid "ground," the original "burr" of which is left untouched in the extreme darks, and no acid, etching or line-work is used in it at all. The usual short descriptions of the method are misleading, because they fail to explain that it is the "ground," and not the "burr" of it only, which is scraped away in greater or smaller degree to produce the varying tones of the design. The necessity of realizing that there are two constituents of the "ground," the "burr" and the indentations out of which the "burr" is raised, will be appreciated later. The "rocking-tool," with which the "ground" is laid, somewhat resembles a carpenter's chisel, but the blade is 3 in. wide and only about 2¾ in. long, whilst the cutting edge, instead of being straight, is curved in the segment of a circle. One side of the blade is deeply engraved with lines from edge to handle, and the ridges which remain between these lines form teeth at the cutting edge when the unengraved side of the tool is bevelled as an ordinary chisel is sharpened.

The tools contain from 35 to 120 teeth to each inch of their width, those with the most teeth producing grounds of the finest texture. The operator rocks the curved edge of the tool from side to side on the bare copper plate, causing the tool to travel forward, whilst each tooth makes an indentation in the copper and throws up a corresponding particle of metal, which is called the "burr." When the whole plate has been so rocked across in 45 to 60 different directions, so that no visible speck of the original bright copper surface remains unfretted by the teeth of the "rocking-tool," the "ground" is termed "full," and is ready for scraping the design. The innumerable particles of copper forming the raised "burr" give to a "full ground" much the appearance of copper-coloured plush, and a print from it, taken before any scraping has been done on it, looks not unlike a piece of black velvet. The lights and semi-tones of the design are produced by subsequent scraping and burnishing.

Assuming that a mezzotint is to be scraped from a lady's portrait by Sir Joshua Reynolds in which a piece of black drapery crosses a white dress—the engraver begins to work on a previously laid "ground" which would print uniformly black before scraping commences. In the extreme darks of the black drapery the raised "burr" is left untouched by the "scraper"—a two-edged steel instrument resembling an ancient Roman sword-blade in miniature, but having a longer point. Working from dark to light, the engraver produces the varying tones of the folds of the black drapery by scraping the raised "burr" down more or less, lowering it in fact so that it will not hold so much ink as where it is left untouched in the extreme darks. In the highest lights of the black drapery all the raised "burr" will have been removed and the original surface of the plate reached, but as yet the engraver has not produced any tone lighter than middle tint (although he has completely modelled up the black drapery), because the indentations out of which the "burr" was raised still remain in the plate and hold ink in printing. In order to produce the infinite gradation of delicate tones in the white dress, or in a sky, the scraping is continued, the indentations being thus made shallower in the passages scraped, and therefore less capable of holding ink, whilst they are obliterated almost entirely in the highest lights. When the mezzotint is finished the black drapery will stand higher than the surface of the plate modelled in a relief composed of the raised "burr," whilst all the tones of the white dress, from middle tint to pure white, will be so many actual depressions in the plate, the highest lights being the deepest. The speck of light in the eye, for instance, is a pit in the plate, surrounded by a tract of more or less raised "burr," which provides the intense black of the pupil and the half-tints of the iris. The difference of surface levels is very appreciable where high-lights impinge on strong darks, but it exists in varying degree all over the plate, and the greatest technical difficulty in pure mezzotint is to obtain adequate "edge" and definition, because the tendency is to remove too much "ground" from the edges of adjacent darks in the course of the constant scrapings necessary to smooth and polish the depressed lights.

In printing a mezzotint a non-fluid ink is thoroughly worked into every part of the plate, and the superfluities wiped off again, leaving as much ink as possible in the darks, the raised "burr." If the bottom of the small lights is not quite smooth, the ink sticks in the roughness and they print dark instead of light, or the printer has to wipe so hard to get the ink out of the depressed lights that he removes too much from the raised darks. In either case loss of definition and contrast of effect results. This inherent difficulty of scraping to a sharp edge caused the use of the "mixed" methods, in which the details were sharpened by outlining them with stipple or line etching.

Mezzotint is the best form of engraving for completeness of representation, but etching is better adapted for sketching from nature or for the expression of any fleeting idea. The two arts have distinct uses and limitations. The art function of true etching as practised by Rembrandt lies in economy of expressive line to suggest the artist's meaning, and that of mezzotint in completion of tonality to explain it. Artistic suggestion, which is not inherent in the solid tones of mezzotint, has to be imparted to the work entirely by the free play of the "scraper" on the "ground," much as the painter attains it on canvas with the brush.

History.

The first reputed mezzotint was produced at Amsterdam in 1643 by Ludwig von Siegen, an officer in the service of the Landgrave of Hesse, and an amateur artist; but the work was a direct drawing on copper with an instrument of comparative precision resembling the roulette rather than a mezzotint, ground laid with the rocking-tool and scraped from dark to light in the present manner of the art. Siegen's innovation was led up to by the previous stipple work of Giulio Campagnola and Janus Lutma; the roulette appears to have been used before his time; and though he shared in the evolution of the rocking-tool, he was not the sole inventor of it. The earliest works referable to the method at the print room of the British Museum afford evidence, though inconclusive, that Prince Rupert, to whom Siegen showed his mode of work in 1654, and possibly also their common friend, Th. Caspar von Fürstenberger, and Rupert's assistant, Vallerant Vaillant, were more or less concerned in the gradual development of mezzotint engraving. The rocking-tool was apparently improved by Abraham Blooteling, a Dutch painter and engraver of fine portrait mezzotints, who worked in Holland and in England about the year 1680.

Rupert brought the new art over to England at the Restoration, and the portrait of Charles II., dated 1669, by William Sherwin, the first English mezzotinter, bears the engraver's acknowledgment of his indebtedness to Rupert for the secrets of the method. Mezzotint continued to be practised for a while on the Continent, but the successors of Sherwin in England so excelled in it that it early acquired abroad the title of "la manière Anglaise," and has since become an exclusively British art. Though used for transcribing the subject-pictures of the great Italian masters, and of Rembrandt, Vandyck and Rubens, almost every kind of subject being later engraved in it, the staple production in mezzotint has always been the portrait. Until the middle of the 18th century the tools continued somewhat archaic, causing in the prints an appearance of warp and woof, like that of ill-woven material, which detracted from reality of representation. The coarseness and unequal depth of the "grounds" offered so much resistance to freedom of execution with the "scraper" that, though the early engravers were quite as good artists as their successors, painter-like touch was not conspicuous in the work until M'Ardell and the interpreters of Sir Joshua Reynolds had improved the tools and technique.

Except for the collector, therefore, the chief attraction in the prints of F. Place and Luttrell, Beckett and Williams, and later those of John Simon, John Smith and John Faber, jun., who were the principal exponents of mezzotint in the last years of the seventeenth and first half of the eighteenth centuries, lies in their long series of portraits after Vandyck, Lely, Kneller and the Dutch painters then practising in England, representing such interesting personages as Charles II. and Nell Gwynn, Addison and Pope, Congreve and Wycherley, Locke and the great duke of Marlborough.

The classics of mezzotint engraving are to be found amongst the best plates after Sir Joshua Reynolds by James M'Ardell, J. R. Smith and Valentine Green, the Watsons, Dickinson, Fisher, Dixon and some others, who worked during the last half of the 18th century. The brushwork of Reynolds was more in harmony with the mezzotint method than the slighter painting technique of Gainsborough and Romney, who were much less frequently engraved, perhaps because it is the highest technical difficulty in mezzotint to render the sharp edges of a sketch. For this reason a typical Gainsborough was never successfully engraved in the method. Though professional publishers and printers existed at this time and earlier, the word "excudit" on an old print, implying "published," not "engraved," the authors of the "Sir Joshua" mezzotints in most cases printed, published and sold their own works, and pure mezzotint, unmixed with etching, was almost exclusively the method they employed. Mezzotints were occasionally printed in colours, notably those engraved later after George Morland, the primary object being to conceal the worn-out condition of the plates.

The departure from pure mezzotint and temporary decay of the art began when, towards the end of the 18th century, Richard Earlom, otherwise a fine artist in the traditional method, notably in translations of Vandyck and Wright of Derby, began to outline the details of his plates with stipple etching in order to avoid the labour and difficulty of scraping them to a sharp edge, using the "ground" alone. Earlom, however, did not destroy the mystery of the rich velvety darks by etching into them. A demand then arose for larger editions than the soft copper plates would yield, and the engravers attempted to meet it by combining mezzotint with positive line-etching throughout the work, thus shortening the labour of scraping the details, and fortifying the darks with lines sunk below the surface of the plate. The harmony of line and tone in some of the prints in this style by S. W. Reynolds and Charles Turner, after Sir Joshua, Hoppner and their contemporaries, was more convincing than the later "mixed style" of Samuel Cousins, because there was a certain artistic significance in the etched line itself apart from the mezzotint tone, but every touch of line in a mezzotint does something to destroy the painter-like quality, and a decadence was in progress.

The same mixed method on copper was used by J. W. M. Turner in his *Liber Studiorum* series of landscape plates, his object being to rival the pen-and-wash drawings of Claude's *Liber Veritatis*. Turner, however, was not so practised in etching or mezzotint as the engravers before mentioned, and the etched foundation of the *Liber* plates was too strong for the mezzotint tone, destroying the breadth of the light, the richness of the darks, and the artistic "keeping" of the whole effect. It is the grand design of Turner reflected in the plates, rather than any quality of mezzotint or etching in them, which appeals to the artist and the connoisseur. Perhaps the greatest success in harmonizing line and tone in one plate was achieved by David Lucas in his "English Landscape" series of mezzotint after John Constable, in which he sharpened his details with the roulette, or with a slight line put in with the point of the scraper as scraping proceeded, retaining the pure "burr" in his darks. Lucas, like Samuel Cousins and his contemporaries, was handicapped by being compelled to work on the steel plates introduced in 1823, and this was the cause of the chief defect of his plates, the excessive opposition of black and white. The warm general tone which assisted the picturesqueness of the 18th century mezzotints was lost by the use of steel, because the ink did not cling to it as it does to the more porous copper. Steel being harder than copper, the rocking-tool penetrated less deeply, raising less "burr," and the consequent loss of force in the darks necessitated the scraping up of the lights to a higher key to force contrast of effect, which was also enhanced by the use of very white paper and a coarse black ink. It was soon found that the unfortified "burr," even on steel, would not yield the constantly increasing numbers of impressions demanded. The labour of scraping sharp lights was greatly enhanced, and though some pure mezzotints were engraved on steel, painter-like touch was practically unattainable on it, and the general effect was cold and uninteresting.

The early work of Samuel Cousins after Lawrence in the comparatively pure method, and the final development of the "mixed style" on steel in his later plates after Reynolds, Millais and Landseer, are referred to in the article on Samuel Cousins.

For nearly forty years pure mezzotint ceased to be practised altogether, and the revival of it, which began in 1880, was led up to by the invention of steel-facing. The competition of photogravure, which steel-facing made a commercial possibility, for a time checked the new movement, but a photogravure, despite a mere surface resemblance to a mezzotint, is a photograph manipulated to imitate an engraving, entirely devoid of artistic individuality. In 1898 for the first time a Society of Mezzotint Engravers was formed to foster the art.

Authorities.—*British Mezzotinto Portraits*, by John Challoner Smith (London, 1878), a standard book of reference, contains a long list of others at p. xiv., pt. i. See also *Lectures on Etching and Mezzotint*, by Hubert von Herkomer, R.A. (London, 1890), the most useful work on the technique. *Etching, Engraving and other Methods of Printing Pictures*, by H. W. Singer and William Strang (London, 1897); *On the Making of Etchings*, by Frank Short (London, 1898), containing a slight reference to mezzotint technique; *Art of Engraving*, by T. H. Fielding (London, 1854); Alfred Whitman, *Masters of Mezzotint* (London, 1898), *Valentine Green* (1902), *Samuel William Reynolds* (1903), *Samuel Cousins* (1904), *Charles Turner* (1907); Gordon Gordain, *James McArdell* (1903), *Thomas Watson, James Watson, Elizabeth Judkins* (1904); W. G. Rawlinson, *Turner's Liber Studiorum, a Description and a Catalogue* (2nd ed., 1906); F. Wedmore's catalogue of the David Lucas mezzotints. A little anonymous book, *A History of the Art of Engraving in Mezzotinto, from Its Origin to the Present Times* [by Dr James Chelsum] (Winchester, 1786), is of considerable interest. Works on the technique are somewhat elementary, and no complete history of the art exists. (G. P. R.)

MFUMBIRO, or Kirunga, general names for a chain of volcanic mountains extending across the Central African, or Albertine, rift-valley immediately north of Lake Kivu. The range, the result probably of recent geological changes, completely blocks the valley at this point, forming a divide between the rivers flowing north to the Nile and the waters of Lake Kivu, connected through Tanganyika with the Congo system. The chain consists of two groups of mountains, surrounded by a vast lava field. The western group lies directly north of Lake Kivu, and contains two active volcanoes, Kirunga-cha-gongo, the nearest to the lake (11,194 ft. high), and Kirunga-namlagira (9711 ft.), some 10 m. further north. The eastern group contains several higher peaks—some rising to needle-like points, others being truncated cones. The most lofty, Karissimbi (14,683 ft.), lies in 29° 27′ 20″ E., 1° 30′ 20″ S. Mikeno, a few miles north and west of Karissimbi, is 14,385 ft. high. The most easterly of the peaks, Muhavuru (13,562 ft.), in 29° 40′ 30″ E., 1° 23′ S., is an isolated sugarloaf-shaped mass with a crater filled with water on its summit. This is the mountain to which the names Mfumbiro and Kirunga were originally applied. Some 6 m. west and a little north of Muhavuru is Sabyino (Sabinjo), 11,881 ft. high. The eastern peaks are snowclad for a part of the year. North of these high mountains is a district, extending towards Albert Edward Nyanza, containing hundreds of low peaks and extinct volcanoes. It is to this region that the name Umfumbira or Mfumbiro is said properly to belong.

Mfumbiro, *i.e.* Muhavuru, was first seen by a white man in 1861, J. H. Speke, in his journey to discover the source of the Nile, obtaining a distant view of the cone, which was also seen by H. M. Stanley in 1876. By its Baganda name of Mfumbiro (cook-house mountains) it figured on the maps somewhat east of its true position, first ascertained by Franz Stuhlmann in 1891. In 1894 Count von Götzen travelled through the volcanic region, and the range was subsequently explored by E. S. Grogan, Major St Hill Gibbons, Captain Herrmann, Dr R. Kandt and others, the principal heights being determined in 1903. In 1907–1908 the range was geologically and topographically examined by the duke of Mecklenberg's expedition. By the Anglo-German agreement of the 1st of July 1890 "Mount Mfumbiro" was included in the British sphere in East Africa.

See Captain Herrmann, "Vulkangebiet des zentralafrikanischen Grabens," in *Mitteil. v. Forsch. u. Gelehrten a. d. deutschen Schutzgebieten*, vol. xvii. (Berlin, 1904), and Adolf Friedrich, duke of Mecklenburg, *Ins Innerste Afrika* (Leipzig, 1909); both give maps.

MHOW, a town of Central India, with British military cantonment, within the native state of Indore, on the Malwa branch of the Rajputana railway, 13 m. S. of Indore. Pop. (1901), 36,039. It is the headquarters of the 5th division of the southern army, and one of the chief military stations of India. There are two high schools, a Zoroastrian and a Canadian mission, the Dorabji Pestonji dispensary, and a gaol.

MIAGAO, a town on the southern coast of the province of Iloilo, island of Panay, Philippine Islands, about 25 m. W.S.W. of the town of Iloilo, the capital. Pop. (1903), 20,656; in the same year the neighbouring town of San Joaquin (pop. 1903, 14,333) was incorporated with Miagao. It has a cool and healthful climate. The neighbouring country is hilly and sterile, but produces sibucao in considerable quantities. The weaving of fabrics of abacá (*Musa textilis*), or Manila hemp, and pineapple fibre is the most important local industry. The language is Panay-Visayan.

MIALL, EDWARD (1809–1881), English Nonconformist divine and journalist, was born at Portsmouth on the 8th of May 1809. He was Congregational minister at Ware (1831) and Leicester (1834), and in 1841 founded the *Nonconformist*, a weekly newspaper in which he advocated the cause of disestablishment. Miall saw that if the programme of Nonconformity was to be carried through it must have more effective representation in Parliament. One of the firstfruits of his work was the entrance of John Bright into parliamentary life; and by 1852 forty Dissenters were members of the House of Commons. This was due largely to the efforts of the Anti-State Church Association, afterwards known as the Liberation Society, which Miall had founded in 1844. The long fight for the abolition of compulsory church-rates was finally successful in 1868, and then in 1870 Miall was prominent in the discussions aroused by the Education Bill. He was at this time M.P. for Bradford (1869–1874), having previously (1852–1867) sat for Rochdale. In 1874 he retired from public life, and received from his admirers a present of ten thousand guineas. He died at Sevenoaks on the 29th of April 1881.

See the *Life*, by A. Miall (1884).

MIAMI, a city and the county-seat of Dade county, Florida, U.S.A., in the S.E. part of the state, on the N. bank of the Miami river and on Biscayne Bay. Pop. (1900), 1681; (1905), 4733; (1910), 5471. It is served by the Florida East Coast railway and by lines of coastwise steamships, and is the point of departure of the P. & O. steamships for Nassau and Havana. Miami is the centre of a farming country in which citrus fruits, especially grape-fruit, pineapples and winter vegetables are raised for northern markets. There is excellent rod-fishing; Spanish and king mackerel and blue-fish are shipped from Miami in large quantities; and in Biscayne Bay there are important sponge fisheries. An alligator "farm" and the Subtropical Laboratory of the U.S. government are points of interest. In the city is Fort Dallas (now abandoned), where American troops were quartered during the Seminole War; and Miami is still the trading point of the Seminole Indians, being immediately south of the Everglades, their home. In 1909 a project was on foot to cut a channel from Miami to Lake Okechobee and from the other side of that lake west to the Gulf at Fort Myers, thus providing an inland waterway and draining much swampy but fertile land. In 1896 there were only two dwellings and one storehouse within the present corporate limits, but in that year the place was chosen as the southern terminal of the Florida East Coast railway, which was afterwards extended towards Key West. Soon afterwards Henry M. Flagler (b. 1830), the owner of the railway, began the construction of the magnificent Royal Palm hotel, and Miami became a popular winter resort. Then came the development of commerce by the improvement of the harbour, by donations from Mr Flagler and grants by the United States government.

MIAMI, a tribe of North American Indians of Algonquian stock. The English called them *Twightwees*, a corruption of the native name, which meant the cry of the crane. They were first found in south-eastern Wisconsin, and in 1764 numbered about 1750. Their civilization was advanced and they lived in stockaded towns. They took part in Pontiac's conspiracy in 1764 and in the American War of Independence and American War of 1812 they fought on the English side. At the close of this war they were greatly reduced in numbers. A few Miami still live on a reservation in Oklahoma and in Wabash county, Indiana.

MIANTONOMO (? –1643), chief of the Narraganset tribe of North American Indians, nephew of their grand sachem, Canonicus (d. 1647). He seems to have been friendly to the English colonists of Massachusetts and Connecticut, though he was accused of being treacherous. In 1636, when under suspicion, he went to Boston to prove his loyalty to the colonists. In the following year he permitted John Mason to lead his Connecticut expedition against the Pequot Indians through the Narraganset country, and in 1638 he signed for the Narraganset the tripartite treaty between that tribe, the Connecticut colonists and the Mohegan Indians, which provided for a perpetual peace between the parties, and he agreed to take under his jurisdiction eighty of the two hundred troublesome Pequot. In 1643 a quarrel broke out between the Mohegan and the Narraganset, and Miantonomo led his warriors against those of Uncas, the Mohegan sachem. He was defeated and captured at what is now Norwich, Conn., was turned over to the Connecticut authorities, and was later tried at Boston by the commissioners of the United Colonies of New England. A committee of five clergymen, to whom his case was referred, recommended that he be executed, and the commissioners accordingly sentenced him to death and chose Uncas as his executioner. Miantonomo, who was kept in ignorance of this sentence, was taken to the scene of his defeat and was there tomahawked in cold blood by Wawequa, the brother of Uncas. There is a monument to Miantonomo in Sachem's Park, Norwich, Conn.

MIANWALI, a town and district of India in the Multan division of the Punjab. The town is situated on the left bank of the Indus, 655 ft. above sea-level. Pop. (1901), 3591. The district was formed in 1901, after the creation of the North-West Frontier Province, out of the Cis-Indus portions of Bannu and Dera Ismail Khan districts. Area 7816 sq. m. Pop. (1901), 424,588, showing an increase of 6·1% in the decade. About three-quarters of the district lies to the east of the Indus. Along the river is a low fertile tract, liable to floods. The remaining upland, known as the Thal, is barren and sandy, cultivable only where irrigation is possible. In the north-east the district includes the western flank of the Salt Range. The part of the district west of the Indus is a level and fairly fertile plain, enclosed by the Chichali and Maidani hills. The chief agricultural products are wheat and other grains and oil-seeds. Hides and wool are also exported, together with small quantities of alum (abundant in the Salt Range), salt (from the Salt and Maidani ranges), and coal of poor quality, which is found at several points. Petroleum has been discovered. The district is served by the Multan-Rawalpindi line of the North-Western railway.

MIAOTSZE, or MIAUTSE, one of the aboriginal tribes of southern China. At one time they occupied a considerable portion of the fertile lands which now form the central province of the empire, but as the Chinese advanced southwards they were driven into the mountain districts of the provinces of Yunnan, Kwei-chow, Kwang-si and Kwang-tung, where they are found at the present day. As early as the reign of King Suan (about 800 B.C.) we read of an expedition having been sent to drive them out of Hu-nan. The last important campaign against them was undertaken by the emperor K'ien-lung, who, having completely subjugated the Eleuths, attacked the Miaotsze, who suffered a crushing defeat, and were compelled to purchase peace by swearing allegiance to their conquerors. They still maintain a semi-independence in their mountain-homes, but are a decaying race, gradually giving way before the Chinese. They are allowed to govern themselves on their own patriarchal system. The Miaotsze of both sexes are shorter and darker-complexioned than the Chinese, their faces are rounder and their features sharper.

See *Sketches of the Miau-tsze*, trans. by E. C. Bridgman; J. Edkins, *The Miautsi Tribes, their History*; and "Quaint Customs in Kwei-chow," *Cornhill Magazine* (Jan. 1872); Playfair, *The Maotzu of Kwei-chow and Yunnan* (London, 1877); A. R. Colquhoun, *Across Chrysé* (1883).

MIAOULIS, ANDREAS VOKOS or BOKOS (1768–1835), Greek admiral and politician, was born in Negropont. The surname Miaoulis, which was added to his family name of Vokos, or Bokos, is said to be derived from the Turkish word *miaoul*, a felucca. He settled in the island of Hydra on the east of the Morea, and when the Greek War of Independence began was known among his fellow townsmen as a trader in corn who had gained wealth, and who made a popular use of his money. He had been a merchant captain, and was chosen to lead the naval forces of the islands when they rose against the government of the Sultan. The islanders had enjoyed some measure of exemption from the worst excesses of the Turkish officials, but suffered severely from the conscription raised to man the Turkish ships; and though they seemed to be peculiarly open to attack by the Sultan's forces from the sea, they took an early and active part in the rising. As early as 1822 Miaoulis was appointed navarch, or admiral, of the swarm of small vessels which formed the insurgent fleet. He commanded the expedition sent to take revenge for the massacre of Chio (see KANARIS) in the same year. He continued to be the naval chief of the Greeks till Lord Dundonald entered their service in 1827, when he retired in order to leave the English officer free to act as commander. In the interval he had had the general direction of the naval side of the Greek struggle for freedom. He had a share in the successful relief of the first siege of Missolonghi in December 1822 and January 1823. In 1824, after the conquest of Psara by the Turks, he commanded the Greek forces which prevented the further progress of the Sultan's fleet, though at the cost of the loss of many fire ships and men to themselves. But in the same year he was unable to prevent the Egyptian forces from occupying Navarino, though he harassed them with some success. During 1825 he succeeded in carrying stores and reinforcements into Missolonghi, when it was besieged for the second time, though he could not avert its fall. His efforts to interrupt the sea communications of the Egyptian forces failed, owing to the enormous disproportion of the two squadrons in the siege and strength of the ships. As the war went on the naval power of the Greeks diminished, partly owing to the penury of their treasury, and partly to the growth of piracy in the general anarchy of the Eastern Mediterranean. When Miaoulis retired to make room for Dundonald the conduct of the struggle had really passed into the hands of the powers. When independence had been obtained, Miaoulis in his old age was entangled in the civil conflicts of his country, as an opponent of Capodistrias and the Russian party. He had to employ his skill in the employment of fireships against them at Poros in 1831. He was one of the deputation sent to invite King Otho to accept the crown of Greece, and was made rear-admiral and then vice-admiral by him. He died on the 24th of June 1835 at Athens.

MICA, a group of widely distributed rock-forming minerals, some of which have important commercial applications. The principal members of the group are muscovite, biotite, phlogopite and lepidolite (*q.v.*). The name mica is probably derived from the Latin *micare*, to shine, to glitter; the German word *glimmer* has the same meaning. The mineral was probably included with selenite under Pliny's term *lapis specularis*.

Mineralogical Characters.—The micas are characterized by a very easy cleavage in a single direction and by the high degree of flexibility, elasticity and toughness of the extremely thin cleavage flakes. They all crystallize in the monoclinic system, often, however, in forms closely resembling those of the rhombohedral or orthorhombic systems. Crystals have usually the form of hexagonal or rhomb-shaped scales, plates or prisms, with plane angles of 60° and 120°, and, with the exception of the basal planes, are only rarely bounded by smooth and well-defined faces. The crystal represented in fig. 1 is bounded by the basal pinacoid *c* (001) parallel to which is the perfect cleavage, the clinopinacoid *b* (010) parallel to the plane of symmetry, and the pyramids *m* (221) and *o* (112). The angles between these pyramids and the basal plane are 85½° and 73° respectively. The prism (110) at 90° from the basal plane is not developed as a crystal face, but is a plane of twinning, the two individuals of the twin being united parallel to the basal plane (fig. 2). The different species of mica have very nearly the same forms and interfacial angles, and they not infrequently occur intergrown together in parallel position. The best developed crystals are those of Vesuvian biotite.

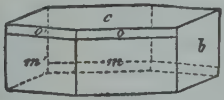

FIG. 1.

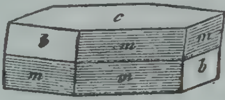

FIG. 2.

When a cleavage flake of mica is struck a sharp blow with a blunt needle-point a six-rayed star of cracks or "percussion figure" is developed: the rays intersect at angles of approximately 60°, and the pair most prominently developed are parallel to the plane of symmetry of the crystal. A similar six-rayed system of cracks, bisecting the angles between the rays of the previous set, is produced when a blunt punch is gradually pressed against a sheet of mica; this is known as the "pressure figure." These cracks coincide with planes of easy separation or of gliding in the crystal; they are especially useful in helping to determine the crystallographic orientation of a cleavage flake of mica when crystal faces are absent. Sheets of mica which have been subjected to earth-movements are frequently cracked and ridged parallel to these directions, and are then valueless for economic purposes.

In their optical characters the micas exhibit considerable variations. The indices of refraction are not high, the mean index being about 1·58–1·60, but the double refraction is very strong (0·04–0·05) and is negative in sign. The angle between the optic axes varies from 70°–50° in muscovite and lepidolite to 10–0° in biotite and phlogopite; the latter are thus frequently practically uniaxial. The acute bisectrix of the optic axes never deviates from the normal to the basal plane by more than a degree or two, hence a cleavage flake of mica will always show an optic figure in convergent light when placed on the stage of a polarizing microscope. The plane of the optic axes may be either perpendicular or parallel to the plane of symmetry of the crystal, and according to its position two classes of mica are distinguished. To the first class, with the optic axial plane perpendicular to the plane of symmetry, belong muscovite, lepidolite, paragonite, and a rare variety of biotite called anomite; the second class includes zinnwaldite, phlogopite, lepidomelane and most biotites. Dark coloured micas are strongly pleochroic. Accurate determinations of the optical orientation, as well as the symmetry of the etching figures on the cleavage planes, seem to suggest that the micas, except muscovite, may be anorthic rather than monoclinic in crystallization.

The different kinds of mica vary from perfectly colourless and transparent—as in muscovite—through shades of yellow, green, red and brown to black and opaque—as in lepidomelane; the former have a pearly lustre and the latter a submetallic lustre on the cleavage surfaces. Sheets of mica very often show coloured rings and bands (Newton's rings), due to the interference of light at the surfaces of internal cleavage cracks. The spec. grav. varies between 2·7 and 3·1 in the different species. The hardness is 2–3; smooth cleavage surfaces can be just scratched with the finger-nail. The micas are bad conductors of heat and electricity, and it is on these properties that many of their technical applications depend.

Inclusions of other minerals are frequently to be observed in mica. Flattened crystals of garnet, films of quartz, and needles of tourmaline are not uncommon. Cleavage sheets are frequently disfigured and rendered of little value by brown, red or black spots and stains, often with a dendritic arrangement of iron oxides. Minute acicular inclusions, probably of rutile, arranged parallel to the rays of the percussion figure, give rise to the phenomenon of "asterism" in some micas, particularly phlogopite: a candle-flame or spot of light viewed through a cleavage sheet of such mica appears as a six-rayed star.

Chemical Composition.—The micas are extremely complex and variable in composition. They are silicates, usually orthosilicates, of aluminium together with alkalis (potassium, sodium, lithium, rarely rubidium and caesium), basic hydrogen, and, in some species magnesium, ferrous and ferric iron, rarely chromium, manganese and barium. Fluorine is also often an essential constituent, and titanium is sometimes present.

The composition of the several species of mica is given by the following formulae, some of which are only approximate. It will be seen that they may be divided into two groups—alkali-micas (potash-mica, &c.) and ferromagnesian micas—which correspond roughly with the division into light and dark micas.

Muscovite	$H_2K\ Al_3(SiO_4)_3$
Paragonite	$H_2Na\ Al_3(SiO_4)_3$
Lepidolite.	$KLi[Al(OH,F)_2]Al(SiO_3)_3$
Zinnwaldite	$(K,Li)_3[Al(OH,F)_2]FeAl_2Si_5O_{16}$
Biotite	$(H,K)_2(Mg,Fe)_2(Al,Fe)_2(SiO_4)_3$
Phlogopite	$[H,K,(MgF)]_3Mg_3Al(SiO_4)_3$

The water which is present in muscovite to the extent of 4 to 6%, and rather less in the other species, is expelled only at a high temperature; it is therefore water of constitution, existing as basic hydrogen or as hydroxyl replacing fluorine.

Roscoelite is a mica in which the aluminium is largely replaced by vanadium (V_2O_3, 30%); it occurs as brownish-green scaly aggregates, intimately associated with gold in California, Colorado and Western Australia.

Various attempts have been made to explain the variations in composition of the micas. G. Tschermak, in 1878, regarded them as isomorphous mixtures of the following fundamental molecules: $H_2KAl_3(SiO_4)_3$, corresponding with muscovite; $Mg_6Si_3O_{12}$, a hypothetical polymer of olivine; and $H_4Si_5O_{12}$, a hypothetical silicic acid. F. W. Clarke (1889–1893) supposes them to be substitution derivatives of normal aluminium orthosilicate $Al_4(SiO_4)_3$, in which part of the aluminium is replaced by alkalis, magnesium, iron and the univalent groups (MgF), (AlF_2),(AlO), (MgOH); an excess of silica is explained by the isomorphous replacement of H_4SiO_4 by the acid $H_4Si_3O_8$.

Artificially formed crystals of the various species of mica have been observed in furnace-slags and in silicate fusions.

Occurrence.—Mica occurs as a primary and essential constituent of igneous rocks of almost all kinds; it is also a common product of alteration of many mineral silicates, both by weathering and by contact- and dynamo-metamorphic processes. In sedimentary rocks it occurs as detrital material.

Muscovite and biotite are commonly found in siliceous rocks, whilst phlogopite is characteristic of calcareous rocks. The best crystallized specimens of any mica are afforded by the small brilliant crystals of biotite, which encrust cavities in the limestone blocks ejected from Monte Somma, Vesuvius. Large sheets of muscovite, such as are of commercial value, are found only in the very coarsely crystallized pegmatite veins traversing granite, gneiss or mica-schist. These veins consist of felspar, quartz and mica, often with smaller amounts of other crystallized minerals, such as tourmaline, beryl and garnet; they are worked for mica in India, the United

States (South Dakota, Colorado and Alabama), and Brazil (Goyaz, Bahia and Minas Geraes). The commercially valuable micas of Canada and Ceylon are mainly phlogopite (*q.v.*), which has a rather different mode of occurrence. The mica mined in India is practically all muscovite. The principal mining districts are those of Hazāribāgh in Bengal and Nellore in Madras; in the former district the mica has usually a ruby tint, whilst in the latter it is more often greenish. In the Inikūrti mine, Nellore, "books" of mica measuring 10 ft. across, and up to 15 ft. across the folia have been found, and rectangular sheets measuring 30 by 24 in. and free from cracks and flaws have frequently been obtained.

Uses.—On account of its transparency and its resistance to fire and sudden changes of temperature, mica has been much used for the windows of stoves and lanterns, for the peep-holes of furnaces, and the chimneys of lamps and gas-burners. At one time it was used for window panes of houses and the port-holes of Russian men-of-war, being commonly known as "Muscovy glass." Spangles of mica are much used for decorative purposes of various kinds, and the mineral was formerly known as *glacies Mariae* (Ger., *Frauenglas*) because of its use for decorating statues of the Virgin. The *lapis specularis* of Pliny, scattered over the Circus Maximus to produce a shining whiteness, was probably mica. Large quantities of ground mica are used in the manufacture of wall-paper, and to produce a frosted effect on toys, stage scenery, &c. Powdered mica is also used in the manufacture of paints and paper, as a lubricant, and as an absorbent of nitro-glycerine and disinfectants. Sheets of mica are used as a surface for painting, especially in India; for lantern slides; for carrying photographic films; as a protective covering for pictures and historical documents; for mounting soft and collapsible natural history specimens preserved in spirit; for the vanes of anemometers; mirrors of delicate physical instruments; for various optical and many other purposes. Being a bad conductor of heat it is used for the packing and jackets of boilers and steam-pipes. Other applications depend on the strength of its resistance to acids.

The most extensive application of mica at the present day is for electrical purposes. Being a bad conductor of electricity it is of value as an insulator, and the smooth flexible sheets are much used in the construction of armatures of dynamos and in other electrical machinery. For various purposes a manufactured material known as "micanite" or "micanite cloth" is much used; this consists of small sheets of mica cemented with shellac or other insulating cement on cloth or paper.

Muscovite and phlogopite are practically the only species used commercially, the former being the more common. Phlogopite is rarely found as colourless transparent sheets and is therefore almost exclusively used for electrical purposes. Many other uses of mica might be mentioned. The potassium it contains renders it of value as a manure. The species lepidolite is largely used for the manufacture of lithium and rubidium salts.

Mining, Preparation and Value.—Mica mining is an industry of considerable importance, especially in India; but here the methods of mining are very primitive and wasteful. In working downwards in open quarries and in tortuous shafts and passages much of the mica is damaged, and a large amount of labour is expended in hauling waste material to the surface. Since the mineral occurs in definite veins, a more satisfactory and economical method of working would be that adopted in metalliferous mines, with a vertical shaft, cross-cuts, and levels running along the strike of the vein: the mica could then be extracted by overhead stopping, and the waste material used for filling up the worked-out excavations.

In dressing mica the "books" are split along the cleavage into sheets of the required thickness, and the sheets trimmed into rectangles with a sharp knife, shears or guillotine, stained and damaged portions being rejected. The dressed sheets are sorted according to size, transparency, colour and freedom from spots or stains. Scrap mica is ground to powder or used in the manufacture of micanite.

The price of mica varies very considerably according to the size, transparency and quality of the sheets. An average price for cut sheets of all sizes is about 4s. per lb, but for large sheets it may be as high as 54s. per lb.

MICAH (מִיכָה), in the Bible, the name prefixed to the sixth in order of the books of the minor prophets.[1] He was a contemporary and fellow-worker of Isaiah. The name in various modifications—*Mīcāiāhū*, *Mīcāiĕhū*, *Mīcāiāh*—is common in the Old Testament, expressing as it does a fundamental point of Hebrew faith: Who is like Yahweh?[2] It was also borne among others by the Danite whose history is given in Judges xvii. seq. (see separate article), by the prophet who opposed Ahab's expedition to Ramoth-Gilead (1 Kings xxii.),[3] and by the son of Jonathan (see SAUL).

The editorial title of the book of Micah declares that Micah prophesied "in the days of Jotham (739–734), Ahaz (733–721) and Hezekiah (720–693), kings of Judah." Nothing in the book itself can claim to belong to the reign of Jotham, but the prophecy against Samaria (i. 5–8) may have been uttered originally before the fall of Samaria in 722, *i.e.* in the reign of Ahaz. In its present form, however, it has been incorporated in a prophecy against Judah, belonging, most probably, to the years 705–701, when a new Palestinian rising provoked Sennacherib's campaign of 701 (Nowack; cf. Marti). This prophetic activity of Micah under Hezekiah is confirmed by the direct statement of Jer. xxvi. 17 seq., where Mic. iii. 12 is quoted ("Zion shall be plowed as a field," &c.). The verse quoted forms the climax of Mic. i.–iii., from which chapters only any certain conclusions as to the prophetic message of the historic Micah can be drawn; the remaining sections of the present book (iv.–v., vi.–vii.) consist, in whole or in greater part, of writings belonging to a later period.

Chs. i.–iii. (with the exception of two verses, ii. 12, 13)[4] are a prediction of judgment on the sins of Judah and Ephraim. In a majestic exordium Yahweh Himself is represented as coming forth in the thunderstorm (cf. Amos i. 2) from His heavenly palace, and descending on the mountains of Palestine, at once as witness against His people, and the executer of judgment on their sins. Samaria is sentenced to destruction for idolatry; and the blow extends to Judah also, which participates in the same guilt (ch. i.). But, while Samaria is summarily dismissed, the sin of Judah is analysed at length in chs. ii. and iii., in which the prophet no longer deals with idolatry, but with the corruption of society, and particularly of its leaders—the grasping aristocracy whose whole energies are concentrated on devouring the poor and depriving them of their little holdings, the unjust judges and priests who for gain wrest the law in favour of the rich, the hireling and gluttonous prophets who make war against every one "that putteth not into their mouth," but are ever ready with assurances of Yahweh's favour to their patrons, the wealthy and noble sinners that fatten on the flesh of the poor. The internal disorders of the realm depicted by Micah are also prominent in Isaiah's prophecies; they were closely connected, not only with the foreign complications due to the approach of the Assyrians, but with the break-up of the old agrarian system within Israel, and with the rapid and uncompensated aggrandisement of the nobles during those prosperous years when the conquest of Edom by Amaziah and the occupation of the port of Elath by his son (2 Kings xiv. 7, 22) placed the lucrative trade between the Mediterranean and the Red Sea in the hands of the rulers of Judah. On the other hand the democratic tone which distinguishes Micah from Isaiah, and his announcement of the impending fall of the capital (the deliverance of which from the Assyrian appears to Isaiah as the necessary condition for the preservation of the seed of a new and better kingdom), are explained by the fact that, while Isaiah lived in the centre of affairs, Micah, a provincial prophet, sees the capital and the aristocracy entirely from the side of a man of the oppressed people, and foretells the utter ruin of both. But this ruin does not present itself to him as involving the captivity or ruin of the nation as a whole; the congregation of Yahweh remains in Judaea when the oppressors are cast out (ii. 5); Yahweh's words are still good to them that walk uprightly; the glory of Israel is driven to take refuge in Adullam,[1] as in the days when David's band of broken men was the true hope of the nation, but there is no hint that it is banished from the land.

---

[1] A confusion between the two prophets of the name has led to the insertion in the Massoretic text of 1 Kings xxii. 28 of a citation from Micah i. 2, rightly absent from the LXX.

[2] See, however, Gray, *Hebrew Proper Names*, p. 157: "In later times they were perhaps virtually synonymous; but this is not to be assumed for early times. The shorter forms may well have had a purely secular reference, signifying 'who is like this child'?"

[3] He is called "the Morashtite" (Mic. i. 1; Jer. xxvi. 18) from his birthplace, Moresheth-Gath. That Micah lived in the Shephelah or Judaean lowland near the Philistine country is clear from the local colouring of i. 10 seq., where a number of places in this quarter are mentioned together (in connexion with the war in Philistia), and their names played upon in a way that could hardly have suggested itself to any but a man of the district. The paronomasia makes the verses difficult, and in i. 14 none of the ancient versions recognizes Moresheth-Gath as a proper name. The word Morashtite (*Mōrashti*) was therefore obscure to them; but this only gives greater weight to the traditional pronunciation with *ô* in the first syllable, which is as old as the LXX., and goes against the view, taken by the Targum both on Micah and on Jeremiah, and followed by some moderns (including Cheyne, E.B., 3198), that Micah came from Mareshah. When Eusebius placed Μωρασθεί near Eleutheropolis it is not likely that he is thinking of Mareshah (Maresa), for he speaks of the former as a village and of the latter as a ruin 2 m. from Eleutheropolis. Jerome too in the *Epit. Paulae* (*Ep.* cviii.), speaking as an eye-witness, distinguishes Morashtim, with the church of Micah's sepulchre, from Maresa. This indeed was after the pretended miraculous discovery of the relics of Micah in A.D. 385; but the name of the village which then existed (*Praef. in Mich.*) can hardly have been part of a pious fraud.

[4] These two verses are a prophecy of restoration; they are admittedly an interruption in their present context (so, *e.g.*, Driver, G. A. Smith); they belong in substance to the second section of the book (iv. v.).

Our only evidence as to the reception of Micah's message by his contemporaries is that afforded by Jer. xxvi. 17 seq., both directly, in the recorded effect on Hezekiah and the people; and indirectly, in the fact that the impression created was remembered a century afterwards. Micah resembles Amos, both in his country origin, and in his general character, which expresses itself in strong emphasis on the ethical side of religion. As the last of the four great prophets of the 8th century he undoubtedly contributed to that religious and ethical reformation whose literary monument is the Book of Deuteronomy.[2]

The remainder of the book bearing the name of Micah falls into two main divisions, viz. iv., v. and vi., vii. Each differs from the first division (i.–iii.) in a marked degree. The second consists mainly of prophecies of restoration including eschatological (iv. 1 seq.)[3] and Messianic (v. 2 seq.) hopes. The third is formed of three or four apparently unrelated passages, on the spirituality of true worship (vi. 1–8), social immorality and its doom (vi. 9–16; vii. 1–6), and Israel's future recovery from present adversity through Divine grace (vii. 7–20). It is improbable that much, if any, of these chapters can be ascribed to Micah himself,[4] not only because their contents are so different from his undoubted work (i.–iii.), for which he was subsequently remembered (Jer. xxvi. 18), but because they presuppose the historic outlook of the Exile, or a later age (*e.g.* iv. 6 seq.; vii. 7 seq.). It is neither psychologically nor historically impossible for a prophet of judgment to be also a prophet of comfort; but the internal evidence of composite and (in whole or part) later authorship must outweigh the traditional attachment of these passages to a MS. containing the work of Micah.

The sequence of thought in chs. iv. v. is really difficult, and has given rise to much complicated discussion. Thus iv. 11–13 stands in direct contradiction to iv. 9, 10, and indeed to iii. 12. The last two passages agree in speaking of the capture of Jerusalem, the first declares Zion inviolable, and its capture an impossible profanation. Such a thought can hardly be Micah's, even if we resort to the violent harmonistic process of imagining that two quite distinct sieges, separated by a renewal of the theocracy, are spoken of in consecutive verses. Another difficulty lies in the words "and thou shalt come even to Babylon" in iv. 10. Micah unquestionably looked for the destruction of Jerusalem as well as of Samaria in the near future and by the Assyrians (i. 9), and this was the judgment which Hezekiah's repentance averted. If these words, therefore, belong to the original context, they mark it as not from Micah's hand; though they might be a later gloss. The prophetic thought is that the daughter (population) of Zion shall not be saved by her present rulers or defensive strength; she must come down from her bulwarks and dwell in the open field; there, and not within her proud ramparts, Yahweh will grant deliverance from her enemies. Opposition to present tyranny expresses itself in recurrence to the old popular ideal of the first simple Davidic kingdom (iv. 8). These old days shall return once more. A new David, like him whose exploits in the district of Micah's home were still in the mouths of the common people (? i. 15), goes forth from Bethlehem to feed the flock in the strength of Yahweh. The kindred Hebrew nations are once more united to their brethren of Israel (cf. Amos ix. 12, Isa. xvi. 1 seq.). The remnant of Jacob springs up in fresh vigour, inspiring terror among the surrounding peoples, and there is no lack of chosen captains to lead them to victory against the Assyrian foe. In the rejuvenescence of the nation the old stays of that oppressive kingship which began with Solomon, the strongholds, the fortified cities, the chariots and horses so foreign to the life of ancient Israel, are no more known; they disappear together with the divinations, the soothsayers, the idols, the *mazzebah* and *asherah* of the high places. Yahweh is king on Mount Zion, and no inventions of man come between Him and His people.

The sixth chapter of Micah presents a very different situation from that of chs. i.–iii. or iv., v. Yahweh appears to plead with His people for their sins, but the sinners are no longer a careless and oppressive aristocracy buoyed up by deceptive assurances of Yahweh's help, by prophecies of wine and strong drink; they are bowed down by a religion of terror, wearied with attempts to propitiate an angry God by countless offerings, and even by the sacrifice of the first-born. Meantime the substance of true religion—justice, charity and a humble walk with God—is forgotten, fraud and deceit reign in all classes, the works of the house of Ahab are observed (worship of foreign gods). Yahweh's judgments are multiplied against the land, and the issue can be nothing else than its total desolation. All these marks may be held to fit exactly the evil times of Manasseh as described in 2 Kings xxi. Cp. vii. 1–6, in which the public and private corruption of a hopeless age is bitterly bewailed, possibly belongs to the same context.

Micah may very well have lived into Manasseh's reign, but the title in i. 1 does not cover a prophecy which certainly falls after Hezekiah's death, and the style has nothing in common with the earlier part of the book. It is therefore prudent to regard the prophecy, with Ewald, as anonymous. Ewald ascribed the whole of chs. vi., vii. to one author. Wellhausen, however, remarks with justice that the thread is abruptly broken at vii. 6, and that verses 7–20[1] represent Zion as already fallen before the heathen and her inhabitants as pining in the darkness of captivity. The hope of Zion is in future restoration after she has patiently borne the chastisement of her sins. Then Yahweh shall arise mindful of His oath to the fathers, Israel shall be forgiven and restored, and the heathen humbled. The faith and hope which breathe in this passage have the closest affinities with the book of Lamentations and Isa. xl.–lxvi. Indeed, as Marti points out (p. 259) the triple division of the book of Micah (i.–iii.; iv., v.; vi., vii.) corresponds with that of the book of Isaiah (i.–xxxix.; xl.–lv.; lvi.–lxvi.) in the character of the three divisions (judgment; coming restoration; prayer for help in adversity) respectively, and in the fact that the first alone gives us pre-exilic writing in the actual words of the prophet to whom the whole book is ascribed. In both cases, it need hardly be said, the great literary and spiritual value of the later passages ought in no way

[1] i. 15; the reference is, however, obscure and uncertain.

[2] See the Introduction to the *Century Bible*, "Deuteronomy and Joshua," by H. Wheeler Robinson.

[3] Mic. iv. 1–3 and Isa. ii. 2–4 are but slightly modified recensions of the same text, and as Isa. ii. is older than the prophecy of Micah, while on the other hand Mic. iv. 4 seems the natural completion of the passage, it is common to suppose that both copy an older prophet. But the words have little connexion with the context in Isaiah, and may be the quotation of a copyist suggested by ver. 5. On the other hand it has been urged that the passage belongs to a later stage of prophetic thought than the 8th century B.C. Reasons making this view the more probable one are given by Wellhausen (p. 142) and Marti (p. 281).

[4] Nowack thinks that iv. 9, 10^a, 14 and v. 10–14 may possibly belong to Micah; Wellhausen recognizes the same possibility, which he extends, however, to vi. 1–8. Marti, who (like Cheyne in *Ency. Bib.*) finds nothing by Micah in iv.–vii., thinks these chapters have crystallized round two central passages, viz. iv. 1–4, and vi. 6–8, whose addition to the first three chapters formed the second stage in the growth of the present book. More conservative views as to authorship are taken by Driver and G. A. Smith, the former suggesting, however, that "the existing Book of Micah consists only of a collection of *excerpts*, in some cases fragmentary excerpts, from the entire series of the prophet's discourses" (*L. O. T.*, ch. vi. § 6).

[1] Regarded by Stade (*Z. A. T. W.*, 1903, p. 164 seq.) as an independent psalm.

to suffer prejudice from critical conditions as to their date and authorship.

LITERATURE.—The chief modern commentaries are those of Nowack (*Die Kleinen Propheten*, 1897; 2nd ed., 1904) and Marti (*Dodekapropheton*, 1904), where detailed references to the older literature may be found; cf. Wellhausen, *Die Kleinen Propheten* (3rd ed., 1898). In English, reference may be made to Cheyne ("Micah," in the *Cambridge Bible*, 1882; 2nd ed., 1895), and to G. A. Smith ("The Book of the Twelve," vol. i., in The *Expositor's Bible*, 1896); also to the articles on "Micah" by Nowack in Hastings's *Dict. of the Bible* (1900), iii. 359, 360, and by Cheyne in the *Ency. Bibl.* (1902), iii. c. 3068–3074, the latter incorporating most of the original article (*Ency. Brit.* 9th ed.) by W. Robertson Smith, which has been revised above. For a review of recent criticism see Cheyne, introduction to W. R. Smith's *The Prophets of Israel*, 2nd ed., pp. xxiii.–xxvii.; also *Ency. Bib. loc. cit.* J. M. P. Smith discusses "The Strophic Structure of the Book of Micah" in a volume of *Old Test. and Semitic Studies: in memory of W. R. Harper* (Chicago, 1908). (W. R. S.; H. W. R.*)

MICAH, in the Bible, a man of the hill-country of Ephraim whose history enters into that of the foundation of the Israelite sanctuary at Dan (Judges xvii. seq.). He had stolen from his mother eleven hundred pieces of silver (for the number cf. Judges xvi. 5), and when she uttered a curse upon the unknown thief he restored the money and she consecrated it to Yahweh. A carved image was made and set up in his private temple together with an ephod-idol and teraphim (objects used in divination, cf. Gen. xxxi. 19, 30; Hos. iii. 4). He employed one of his sons to serve as priest, but when a Levite from Bethlehem in Judah came along he gladly installed him as "father and priest." When the tribe of Dan subsequently sought new territory and sent men to search for a suitable district they passed by Micah's house, recognized the Levite and requested an oracle from him. When, later, they migrated, they despoiled the sacred place and carried off the gods and priest to their newly won home at Laish.

MICA-SCHIST, in petrology, a rock composed essentially of mica and quartz, and having a thin parallel-banded or foliated structure, with lamellae rich in mica alternating with others which are principally quartz. They split readily along the micaceous films, and have smooth or slightly uneven surfaces covered with lustrous plates of muscovite or biotite; the quartzose lamellae are often visible only when the specimens are looked at edgewise. Mica-schists are very common in regions of Archean rocks accompanying gneisses, crystalline limestones and other schists. Some have a flat banding yielding smooth slabs; others are crumpled or contorted with undulating foliation. Occasionally the quartz forms elliptical lenticles or "eyes." In some cases mica composes nearly the whole of the rock, in others quartz preponderates so that they approach quartz-schists and quartzites.

The mica may be muscovite or biotite; both are often present, while paragonite and green fuchsite or chrome-mica are not so common. In addition to quartz there may be a small amount of feldspar, usually albite. A great number of accessory minerals are known in mica-schists, and when these are conspicuous or important they may be regarded as constituting special varieties receiving distinctive names. Garnet, in rounded red crystals, not uncommonly idiomorphic, is the most frequent. Brown staurolite, pinkish andalusite, and grey or blue kyanite occur in some kinds of mica-schist, separately or together. The white mica-schist of the St Gothard contains kyanite and staurolite. Graphite (or graphitoid) is also a very frequent ingredient of these rocks, giving them a leaden grey colour and causing them to soil the fingers when handled. In some mica-schists there is much calcite (calc-mica-schists); and hornblende, scapolite and augite are often seen in rocks of this sort. Tourmaline occurs, sometimes in large black prisms but more commonly in minute crystals visible only in microscopic sections. Rutile in tiny prisms, ilmenite and hematite in black or brown scales, zircon, apatite, granules of epidote or zoisite chlorite, chloritoid and pyrites occur with more or less frequency in the rocks of this group.

Mica-schists are in nearly all cases sedimentary rocks which have been recrystallized and have obtained a schistose structure during the process. This can be proved by their chemical composition, which is very much the same as that of clays, shales and slates. In some districts it is possible to trace every gradation from a slate (*q.v.*) to a mica-schist, the intermediate stages being represented by phyllites (*q.v.*) which consist of quartz, muscovite and chlorite, and are neither so crystalline nor so well foliated as the schists. In a few places, *e.g.* Bergen in Norway, fossils have been found in mica-schists. The association of quartzites and quartz-schists, graphite-schists and crystalline limestones with mica-schists in the field is explained by the fact that all these rocks are altered sediments, viz. sandstones, carbonaceous shales and limestones.

Under the microscope the appearance presented by mica-schists differs according to whether the rock is cut parallel to or across the planes of foliation. In the latter case thin alternating bands composed of black or brown mica, and of quartz, cross the field of view (see PETROLOGY, Plate 4, fig. 8). The mica scales have their cleavages and their flat sides parallel; the quartz occurs in rounded, elliptical or irregular grains, with usually a small admixture of feldspar (albite, oligoclase, orthoclase); apatite and iron oxides are rarely absent from these rocks. If garnet is present it may form large well-shaped crystals containing innumerable enclosures of quartz, biotite and iron ores; in some cases the garnets are cracked as if they had been broken by the pressures to which the rock had been subjected. Often the garnets are surrounded by small "eyes" of quartz, and they may be embedded in green chlorite, which is probably a secondary or decomposition product. Some mica-schists are rich in iron oxides and pass into haematite-schists (itabirites). When graphite occurs in mica-schists its crystals are small flat plates perfectly opaque even in the thinnest sections.

Like all metamorphic rocks, mica-schists are principally found in Archean areas; the great majority of them are of pre-Cambrian age. There are, however, in the Alps, Himalayas, &c., many rocks of this sort which are believed to be secondary or even tertiary; the evidence for this is not in all cases satisfactory, as of course the fossils, which if preserved would be sufficient to prove it, are nearly always destroyed by the metamorphism. Mica-schists are rarely of economic value, being too fissile for building-stones and too brittle for roofing-slates. They are of wide-spread distribution in the Scottish Highlands, Norway and Sweden, Bohemia, Saxony, Brittany, the Alps, many parts of North America, &c. (J. S. F.)

MICCA, PIETRO, Piedmontese soldier (d. 1706), was born at Andorno, and achieved fame by his death in the defence of Turin. During the siege of that city by the French in 1706 a party of the besiegers had succeeded in penetrating by surprise into the moat of the fortress on the night of August 29–30, and would undoubtedly have captured it had not Micca, a soldier in the engineers, fired a mine, with the result that they were blown into the air and the rest of the force driven back with heavy losses. Micca's heroism has been the subject of poems, plays and romances. But, according to Count Giuseppe Solaro della Margherita, the commander of the Turin garrison at the time, it was through a miscalculation of the pace of the fuse. and not by deliberate intent, that he sacrificed his life.

See A. Manno *Pietro Micca ed il generale conte Solaro della Margherita* (Turin, 1883).

MICHAEL (Hebrew מִיכָאֵל, "Who is like God?"), an Old Testament name, synonymous with Micaiah or Micah (Num. xiii. 13; 1 Chron. v. 13 *et passim*). In the book of Daniel the name is given to one of the chief "princes" of the heavenly host, the guardian angel or "prince" of Israel (Dan. x. 13, 21; xii. 1; cf. Enoch xx. 5 and possibly Mal. iii. 1), and as such he naturally appears in Jewish theosophy as the greatest of all angels, the first of the four (or seven) who surround the throne of God, and the antagonist of Sammael, the enemy of God. He holds the secret of the mighty "word" by which God created heaven and earth (Enoch lxix. 14), and was "the angel who spoke to Moses in the Mount" (Acts vii. 38). It was through Babylonian and Persian influence that names were given to the angels, and according to Kohut (*Jüd. Angel.* p. 24) Michael is parallel to Vohumano, "Ahura's first masterpiece," one of the Zoroastrian Amesha-spentas or archangels. It is as guardian angel of Israel, or of the Church, the true Israel, that Michael appears in Jude 9 and Rev. xii. 7. This latter passage is of distinctly pre-Christian origin; it is not the Child that overthrows Satan, the figure of the Messiah is ousted by that of Michael. There is also here a relic of the primeval Babylonian myth of the struggle between the light god Marduk and the forces of chaotic darkness. In the Western Church the festival of St Michael and All Angels (Michaelmas) is celebrated on the 29th of September; it appears to have grown out of a local celebration of the dedication of a church of St Michael either at Mount Garganus in Apulia or at Rome, and was a great day by the beginning of the 9th century. The Greek Church dedicates the 8th of November to St Michael, St Gabriel and All Angels.

MICHAEL (1596–1645), tsar of Russia, was the first tsar of the house of Romanov, being the son of Theodore Nekitich Romanov, afterwards the Patriarch Philaret (*q.v.*), and Xenia Chestovaya, afterwards the nun Martha. He was elected unanimously tsar of Russia by a national assembly on the 21st of February 1613, but not till the 24th of March did the delegates of the council discover the young tsar and his mother at the Ipatievsky monastery near Kostroma. At first Martha protested that her son was too young and tender for so difficult an office in such troublesome times. At the last moment, however, Michael consented to accept the throne, but not till the weeping boyars had solemnly declared that if he persisted in his refusal they would hold him responsible to God for the utter destruction of Muscovy. In so dilapidated a condition was the capital at this time that Michael had to wait for several weeks at the Troitsa monastery, 75 m. off, before decent accommodation could be provided for him at Moscow. He was crowned on the 22nd of July. The first care of the new tsar was to clear the land of the robbers that infested it. Sweden and Poland were then got rid of respectively by the peace of Stolbova (March 10, 1617) and the truce of Deulina (Feb. 13, 1619). The most important result of the truce of Deulina was the return from exile of the tsar's father, who henceforth took over the government till his death in October 1633, Michael occupying quite a subordinate position. He was a gentle and pious prince who gave little trouble to any one and effaced himself behind his counsellors. Fortunately for him they were relatively honest and capable men. Michael's failure to wed his daughter Irene with Prince Waldemar of Denmark, in consequence of the refusal of the latter to accept orthodoxy, so deeply afflicted him as to contribute to bring about his death on the 12th of July 1645.

See R. Nisbet Bain, *The First Romanovs* (Lond., 1905). (R. N. B.)

MICHAEL, the name of nine East-Roman emperors.

Michael I. Rhangabes (d. 845), an obscure nobleman who had married Procopia, the daughter of Nicephorus I., and been made master of the palace. He was made emperor in a revolution against his brother-in-law, Stauracius (811).

Elected as the tool of the bigoted orthodox party in the Church, Michael diligently persecuted the iconoclasts on the northern and eastern frontiers of the empire, but meanwhile allowed the Bulgarians to ravage a great part of Macedonia and Thrace; having at last taken the field in the spring of 813, he was defeated near Bersinikia, and Leo the Armenian was saluted emperor in his stead in the following summer. Michael was relegated as a monk to the island of Prote, where he lived unmolested till his death in 845.

Michael II., called Psellus, "the stammerer," emperor 820–829, was a native of Amorium in Phrygia, who began life as a private soldier, but rose by his talents to the rank of general. He had favoured the enthronement of his old companion in arms Leo the Armenian (813), but, detected in a conspiracy against that emperor, had been sentenced to death in December 820; his partisans, however, succeeded in assassinating Leo and called Michael from the prison to the throne. The principal features of his reign were a struggle against his brother general, Thomas, who aimed at the throne (822–824); the conquest of Crete by the Saracens in 823; and the beginning of their attacks upon Sicily (827). In spite of his iconoclastic sympathies, he endeavoured to conciliate the image-worshippers, but incurred the wrath of the monks by entering into a second marriage with Euphrosyne, daughter of Constantine VI., who had previously taken the veil.

Michael III. (839–867), "the drunkard," was grandson of Michael II., and succeeded his father Theophilus when three years old (842). During his minority the empire was governed by his mother Theodora, who in spite of several defeats inflicted upon her generals maintained the frontiers against the Saracens of Bagdad and Crete. The regent displayed her religious zeal by restoring image-worship (842) and persecuting the Paulician heretics, but she entirely neglected the education of her son. As a result Michael grew up a debauchee, and fell under the sway of his uncle Bardas, who induced him to banish Theodora to a convent and practically assumed the chief control (857). Bardas justified this usurpation by introducing various internal reforms; in the wars of the period Michael himself took a more active part. During a conflict with the Saracens of the Euphrates (856–63), the emperor sustained a personal defeat (860), which was retrieved by a great victory on the part of his uncle Petronas in Asia Minor. In 861 Michael and Bardas invaded Bulgaria and secured the conversion of the king to Christianity. On sea the empire suffered under the ravages of the Cretan corsairs; and in 865 the first pillaging expedition of the Russians endangered the Bosporus. In 867 Michael was assassinated by Basil the Macedonian, a former groom, who had overthrown the influence of Bardas and in 866 been associated in the Empire.

Michael IV. (d. 1041), "the Paphlagonian," owed his elevation to Zoe, daughter of Constantine VIII., who was the wife of Romanus III., but becoming enamoured of Michael, her chamberlain, poisoned her husband and married her attendant (1034). Michael, however, being of a weak character and subject to epileptic fits, left the government in the hands of his brother, John the Eunuch, who had been first minister of Constantine and Romanus. John's reforms of the army and financial system revived for a while the strength of the Empire, which held its own successfully against its foreign enemies. On the eastern frontier the important post of Edessa was relieved after a prolonged siege. The western Saracens were almost driven out of Sicily by George Maniakes (1038–40); but an expedition against the Italian Normans suffered several defeats, and after the recall of Maniakes most of the Sicilian conquests were lost (1041). In the north the Serbs achieved a successful revolt (1040), but a dangerous rising by the Bulgarians and Slavs which threatened the cities of Thrace and Macedonia was repressed by a triumphant campaign which the decrepit emperor undertook in person shortly before his death (1041).

Michael V. Calaphates, or "the caulker," nephew and successor of the preceding, surnamed after the early occupation of his father. He owed his elevation (Dec. 1041) to his uncle John, whom along with Zoe he almost immediately banished; this led to a popular tumult in consequence of which he was dethroned after a brief reign of four months, and relegated to a monastery. His unpopularity seems largely due to his attempts at administrative reform, which were strongly resented by the dominant classes.

Michael VI., "the warlike," was already an old man when chosen by the empress Theodora as her successor shortly before her death in 1056. He was unable to check the disaffection of the feudal aristocracy, who combined with an officer named Isaac Comnenus to depose him. After a successful battle in Phrygia, the rebels had no difficulty in dethroning Michael (1057), who spent the rest of his life in a monastery.

Michael VII. Ducas, or Parapinaces, was the eldest son of Constantine X. Ducas. After a joint reign with his brothers, Andronicus I. and Constantine XI. (1067–1071), he was made sole emperor through his uncle John Ducas. The feebleness of Michael, whose chief interest lay in trifling academic pursuits, and the avarice of his ministers, was disastrous to the empire. As the result of anarchy in the army, the Byzantines lost their last possessions in Italy (1071), and were forced to cede a large strip of Asia Minor which they were unable to defend against the Seljuk Turks (1074). These misfortunes, which were but partially retrieved by the suppression of a Bulgarian revolt (1073), caused widespread dissatisfaction. In 1078 two generals, Nicephorus Bryennius and Nicephorus Botaniates, simultaneously revolted. Michael resigned the throne with hardly a struggle and retired into a monastery. His nickname *Parapinaces* ("starver") was due to his causing the price of wheat to rise.

Michael VIII. Palaeologus (1234–1282) was the son of Andronicus Palaeologus Comnenus and Irene Angela, the granddaughter of Alexius Angelus, emperor of Constantinople. At an early age he rose to distinction, and ultimately became commander of the French mercenaries in the employment of the emperors of Nicaea. A few days after the death of Theodore Lascaris II. in 1259, Michael, by the assassination of Muzalon (which he is believed but not proved to have encouraged) became joint guardian with the patriarch Arsenius of the young emperor, John Lascaris, then a lad of eight years. Afterwards invested with the title of "despot," he was finally proclaimed joint-emperor and crowned alone at Nicaea on the 1st of January 1260. In July 1261 Michael, who had attacked Constantinople with the help of the Genoese, conquered the town through his general Strategopoulos. He thereupon had John Lascaris blinded and banished. For this last act he was excommunicated by Arsenius, and the ban was not removed until six years afterwards (1268) on the accession of a new patriarch. In 1263 and 1264 respectively, Michael, with the help of Urban IV., concluded peace with Villehardouin, prince of Achaia, and Michael, despot of Epirus, who had previously been incited by the pope to attack him, but had been decisively beaten at Pelagonia in Thessaly (1259); Villehardouin was obliged to cede Mistra, Monemvasia and Maina in the Morea. Subsequently Michael was involved in wars with the Genoese and Venetians, whose influence in Constantinople he sought to diminish by maintaining the balance of strength between them. In 1269 Charles of Sicily, aided by John of Thessaly, made war with the alleged purpose of restoring Baldwin to the throne of Constantinople, and pressed Michael so hard that he consented to send deputies to the council of Lyons (1274) and there accept the papal supremacy. The union thus brought about between the two Churches was, however, extremely distasteful to the Greeks, and the persecution of his "schismatic" subjects to which the emperor was compelled to resort weakened his power so much that Martin IV. was tempted to enter into alliance with Charles of Anjou and the Venetians for the purpose of reconquering Constantinople. The invasion, however, failed, and Michael so far had his revenge in the "Sicilian Vespers," which he helped to bring about. He died in Thrace in December 1282. In reconstituting the Byzantine Empire Michael restored the old administration without endeavouring to correct its abuses. By debasing the coinage he hastened the decay of Byzantine commerce.

MICHAEL IX. PALAEOLOGUS, was the son of Andronicus II. and was associated with him on the throne from 1295, but predeceased him (1320). He took the field against the Turks (1301, 1310) and against the Grand Catalan Company (1305), but was repeatedly defeated.

See Gibbon's *Decline and Fall* (ed. Bury, 1896); G. Finlay, *Hist. of Greece* (ed. 1877); G. Schlumberger, *l'Epopée byzantine* (1896); J. Bury, in *Eng. Hist. Rev.* (1889); Meliarakes, *'Ιστορία τοῦ βασιλείου τῆς Νικαίας καὶ τοῦ δεσποτάτου τῆς 'Ηπείρου*, pp. 539–627 (Athens, 1898).

MICHAEL OBRENOVICH III. (1823–1868), Prince of Servia, was the youngest son of Prince Milosh, the founder of the Obrenovich dynasty. After the abdication of his father (1839) and the death of his elder brother Milan Obrenovich II. (1840) he ascended the throne of Servia. He wished to continue the work of his father, in liberating all the Servian people, and if possible all other Balkan Christians, from direct Turkish rule. But while this programme made the Sultan hostile, it also failed to win the support of Austria, which did not wish the Eastern Question to be opened by the ambitious Servian. The support which his aspirations found in Russia increased Turkey's and Austria's suspicions of the prince's activity. At the same time the political situation at home was not favourable to his anti-Turkish policy. The power was in the hands of men who had forced Obrenovich I. to abdicate, and feared that Obrenovich III. might avenge his father. They thought it safer for them to replace him on the throne by a man who was not an Obrenovich, and who would be personally obliged to them for his elevation. These motives were at the bottom of the revolt, started and led by Vuchich in August 1842, the outcome of which was that Prince Michael left the country and that his equerry, Alexander Karageorgevich, was elected Prince of Servia. As an exile Prince Michael lived principally in Vienna, improving his education by studies and travels, and frequently visiting England. He constantly refused to agree to suggestions for his restoration by forcible means. His device was *Tempus et meum jus*, "Time and my right." He supported Servian authors and artists, and wrote himself a book in defence of his father Milosh against the attacks of Cyprian Robert. He wrote poetry too, and some of his songs, set to beautiful music, were very popular amongst the Servians. He married in 1856 the beautiful Julia, Countess Hunyadi.

In 1858 the Servians, having dethroned Prince Karageorgevich, recalled Michael's father Milosh Obrenovich I. Michael returned to Servia, and on his father's death (1860) ascended the Servian throne for the second time. His proclamation "that henceforth the law is the highest will in Servia," opened a new era of strict legality and at the same time of entire emancipation from foreign influences, and more especially from Turkey's interference with the internal affairs of Servia. The old constitution, granted to Servia by the sultan as the suzerain and the tsar as the protector of Servia as far back as 1839, was discarded and replaced by one which limited the power of the oligarchic senate and gave a certain share in legislation to the "Narodna Skupshtina" (the National Assembly). He established the Servian national army and increased the regular army. Reforms in all branches of public administration were introduced, and Servia, until then a half-oriental and half-patriarchal state, was resolutely led to become a civilized country in a European sense. When in 1862 the Turkish garrison bombarded the town of Belgrade from its citadel, Prince Michael, supported by the European diplomacy, succeeded in obtaining evacuation of some of the smaller forts in Servia, but the strong fortress of Belgrade still remained garrisoned by the Turkish troops. Prince Michael now made vigorous political and military preparations for war against Turkey. He made secret arrangements with the Bulgarian, Bosnian and Albanian leaders, an alliance with Montenegro and an understanding with Greece, with the object that they all should rise if Servia declared war on Turkey. He even succeeded in obtaining Austria's promise, that it would observe an attitude of friendly neutrality and would have nothing against an eventual annexation of the largest part of Bosnia to Servia, and he secured to himself the sympathies of Napoleon III. and his government. In the beginning of 1867 he formally asked the Porte to withdraw the Turkish garrisons from the fortress of Belgrade, as well as from other two fortresses of minor importance (Shabats and Smederevo (Semendria)). For some time the chances were that a war would take place that spring (1867) between Servia and Turkey, but peace was kept by the action of Great Britain, who advised the sultan to withdraw the Turkish garrisons from the Servian fortresses; and this advice, backed by Russia, France and Austria, prevailed at last with the sultan. On the 26th of April 1867 the fortresses were delivered over to Prince Michael, who shortly afterwards went to Constantinople to thank the sultan personally.

Prince Michael's policy had triumphed. But his success was short-lived. A group of young men, mostly educated in France and Germany, now started a liberal movement under the leadership of Yovan Ristich (or Ristitch). They wanted a more liberal constitution than that which Prince Michael had given; and this movement tended to qualify his popularity. Meanwhile the prince contemplated divorce from his wife Princess Julia, by whom he had no children, and marriage with the daughter of his cousin Madame Anka Constanitinovich; and the adherents of the exiled Karageorgevich dynasty were alarmed at the prospect of his eventually having legal heirs to the throne. A former private secretary to Prince Alexander Karageorgevich, and two of the same prince's brothers-in-law, formed a conspiracy, which resulted in the brutal assassination of Prince Michael on the 29th of May (June 10 (O.S.), 1868), whilst he was walking in the park of Koshutnyak, a few miles distant from Belgrade. (C. Mi.)

MICHAELIS, JOHANN DAVID (1717–1791), German biblical scholar and teacher, a member of a family which had the chief part in maintaining that solid discipline in Hebrew and the cognate languages which distinguished the university of Halle in the period of Pietism. Johann Heinrich Michaelis (1668–1738) was the chief director of A. H. Francke's *Collegium orientale theologicum*, a practical school of biblical and oriental philology then quite unique, and the author of an annotated Hebrew Bible and various exegetical works of reputation, especially the *Adnotationes uberiores in hagiographos* (1720). In his chief publications J. H. Michaelis had as fellow-worker his sister's son Christian Benedikt Michaelis (1680–1764), the father of Johann David, who was likewise influential as professor at Halle, and a sound scholar, especially in Syriac. J. D. Michaelis was trained for academical life under his father's eye. At Halle he was influenced, especially in philosophy, by Sigmund J. Baumgarten (1706–1757), the link between the old Pietism and J. S. Semler, while he cultivated his strong taste for history under Chancellor Ludwig. In 1739–1740 he qualified as university lecturer. One of his dissertations was a defence of the antiquity and divine authority of the vowel-points in Hebrew. His scholarship still moved in the old traditional lines, and he was also much exercised by religious scruples, the conflict of an independent mind with that submission to authority at the expense of reason encouraged by the Lutheranism in which he had been trained. A visit to England in 1741–1742 lifted him out of the narrow groove of his earlier education. In passing through Holland he made the acquaintance of Albert Schultens (1686–1750), whose influence on his philological views became all-powerful a few years later. At Halle Michaelis felt himself out of place, and in 1745 he gladly accepted an invitation to Göttingen as *privatdozent*. In 1746 he became professor extraordinarius, in 1750 ordinarius, and in Göttingen he remained till his death in 1791.

His intellect was active in many directions; universal learning indeed was perhaps one of his foibles. Literature—modern as well as ancient—occupied his attention; one of his works was a translation of four parts of *Clarissa*; and translations of some of the then current English paraphrases on biblical books manifested his sympathy with a school which, if not very learned, attracted him by its freer air. His oriental studies were reshaped by diligent perusal of the works of Schultens; for the Halle school, with all its learning, had no conception of the principles on which a fruitful connexion between Biblical and Oriental learning could be established. His linguistic work indeed was always hampered by the lack of manuscript material, which is felt in his philological writings, *e.g.* in his valuable *Supplementa* to the Hebrew lexicons (1784–1792).[1] He could not become such an Arabist as J. J. Reiske (1716–1774); and, though for many years the most famous teacher of Semitic languages in Europe, he had little of the higher philological faculty, and neither his grammatical nor his critical work has left a permanent mark, with the exception perhaps of his text-critical studies on the Peshitta.[2] His tastes were all for such studies as history, antiquities, and especially geography and natural science. He had in fact started his university course as a *medicinae cultor*, and in his autobiography he half regrets that he did not choose the medical profession. In geography he found a field hardly touched since Samuel Bochart, in whose footsteps he followed in the *Spicilegium geographiae hebraeorum exterae post Bochartum* (1769–1780); and to his impulse we owe the famous Eastern expedition conducted by Carsten Niebuhr. In spite of his doctrinal writings—which at the time made no little noise, so that his *Compendium of Dogmatic* (1760) was confiscated in Sweden, and the knighthood of the North Star was afterwards given him in reparation—it was the natural side of the Bible that really attracted him, and no man did more to introduce the modern method of studying Hebrew antiquity as an integral part of ancient Eastern life.

The personal character of Michaelis can be read between the lines of his autobiography with the aid of the other materials collected by J. M. Hassencamp (1743–1797) the editor (*J. D. Michaelis Lebensbeschreibung*, &c., 1793). The same volume contains a full list of his works. Besides those already mentioned it is sufficient to refer to his New Testament *Introduction* (the first edition, 1750, preceded the full development of his powers, and is a very different book from the later editions), his reprint of Robert Lowth's *Praelectiones* with important additions (1758–1762), his German translation of the Bible with notes (1773–1792), his *Orientalische und exegetische Bibliothek* (1775–1785) and *Neue O. and E. Bib.* (1786–1791), his *Mosaisches Recht* (1770–1771) and his edition of E. Castle's *Lexicon syriacum* (1787–1788). His *Litterarischer Briefwechsel* (1794–1796) contains much that is interesting for the history of learning in his time.

MICHAUD, JOSEPH FRANÇOIS (1767–1839), French historian and publicist, was born of an old family on the 19th of June 1767, at Albens, Savoy, was educated at Bourg-en-Bresse, and afterwards engaged in literary work at Lyons, where the events of 1789 first called out the strong dislike to revolutionary principles which manifested itself throughout the rest of his life. In 1791 he went to Paris, where, not without danger, he took part in editing several royalist journals. In 1796 he became editor of *La Quotidienne*, for his connexion with which he was arrested after the 13th of Vendémiaire; he succeeded in escaping his captors, but was sentenced to death *par contumace* by the military council. Having resumed the editorship of his newspaper on the establishment of the Directory, he was again proscribed on the 18th of Fructidor, but at the close of two years returned to Paris when the consulate had superseded the Directory. His Bourbon sympathies led to a brief imprisonment in 1800, and on his release he for the time abandoned journalism, and began to write or edit books. Along with his brother and two colleagues he published in 1806 a *Biographie moderne, ou dictionnaire des hommes qui se sont fait un nom en Europe depuis 1789*, the earliest work of its kind; and in 1811 appeared the first volume of his *Histoire des croisades* and also the first volume of his *Biographie universelle*. In 1814 he resumed the editorship of *La Quotidienne*, and in the same year was elected Academician. In 1815 his brochure entitled *Histoire des quinze semaines ou le dernier règne de Bonaparte* met with extraordinary success, passing through twenty-seven editions within a very short time. His political services were now rewarded with the cross of an officer in the Legion of Honour and the modest post of king's reader, of which last he was deprived in 1827 for having opposed Peyronnet's "Loi d'Amour" against the freedom of the Press. In 1830–1831 he travelled in Syria and Egypt for the purpose of collecting additional materials for the *Histoire des croisades*; his correspondence with a fellow explorer, J. J. F. Poujoulat, consisting practically of discussions and elucidations of various points in that work, was afterwards published (*Correspondance d'orient*, 7 vols., 1833–1835). Like the *Histoire*, it is more interesting than exact. The *Bibliothèque des croisades*, in four volumes more, contained the "Pièces justificatives" of the *Histoire*. Michaud died on the 30th of September 1839, at Passy, where his home had been since 1832.

His *Histoire des croisades* was published in its final form in six volumes in 1840 under the editorship of his friend Poujoulat (9th ed., with appendix, by Huillard-Bréholles, 1856). Michaud, along with Poujoulat, also edited *Nouvelle collection des mémoires pour servir à l'histoire de France* (32 vols., 1836–1844). See Sainte-Beuve, *Causeries du lundi*, vol. vii.

MICHAUX, ANDRÉ (1746–1802), French botanist and traveller, was born at Versailles on the 7th of March 1746. In 1779 he spent some time botanizing in England, and in 1780 he explored Auvergne, the Pyrénées and the north of Spain. In 1782 he was sent by the French government on a botanical mission to Persia. His journey began unfavourably, as he was robbed by Arabs of all his equipment except his books; but he gained influential support in Persia, having cured the shah of a dangerous illness. After two years he returned to France with a fine herbarium, and also introduced numerous Eastern plants into the botanic gardens of France. In 1785 he was sent by the French government to North America, and travelled with his son François André (1770–1855) through Canada,

---

[1] By a strange fortune of war it was the occupation of Göttingen by the French in the Seven Years' War, and the friendly relations he formed with the officers, that procured him the Paris MS. from which he edited Abulfeda's description of Egypt.

[2] *Curae in actus apostolorum syriacos* (1755).

Nova Scotia and the United States. On his return to France in 1797 he was shipwrecked and lost most of his collections. In 1800 he went to Madagascar to investigate the flora of that island, and died there on the 16th of November 1802. His work as a botanist was chiefly done in the field, and he added largely to what was previously known of the botany of the East and of America.

He wrote two valuable works on North American plants—the *Histoire des chênes de l'Amérique septentrionale* (1801), with 36 plates, and the *Flora Boreali-Americana* (2 vols., 1803), with 51 plates. His son François published a *Histoire des arbres forestiers de l'Amérique septentrionale* (3 vols., 1810–1813), with 156 plates, of which an English translation appeared in 1817–1819 as *The North American Sylva*.

MICHEL, CLAUDE, known as CLODION (1738–1814), French sculptor, was born on the 20th of December 1738 in Nancy. Here and probably in Lille he spent the earlier years of his life. In 1755 he came to Paris and entered the workshop of Lambert Sigisbert Adam, his maternal uncle, a clever sculptor. He remained four years in this workshop, and on the death of his uncle became a pupil of J. B. Pigalle. In 1759 he obtained the grand prize for sculpture at the Académie Royale; in 1761 he obtained the first silver medal for studies from models; and in 1762 he went to Rome. Here his activity was considerable between 1767 and 1771. Catherine II. was eager to secure his presence in St Petersburg, but he returned to Paris. Among his patrons, which were very numerous, were the chapter of Rouen, the states of Languedoc, and the *Direction générale.* His works were frequently exhibited at the Salon. In 1782 he married Catherine Flore, a daughter of the sculptor Augustin Pajou, who subsequently obtained a divorce from him. The agitation caused by the Revolution drove Clodion in 1792 to Nancy, where he remained until 1798, his energies being spent in the decoration of houses. Among Clodion's works are a statue of Montesquieu, a "Dying Cleopatra," and a chimney-piece at present in the South Kensington Museum. One of his last groups represented Homer as a beggar being driven away by fishermen (1810). On the 29th of March 1814 Clodion died in Paris, on the eve of the invasion of Paris by the allies.

Thirion's *Les Adam et Clodion* (Paris, 1885) contains a list of the sculptor's works sold between 1767 and 1884. See also A. Jacquot, *Les Adam et les Michel et Clodion* (Paris, 1898).

MICHEL, CLÉMENCE LOUISE (1830–1905), French anarchist, called *la Vierge rouge de Montmartre*, was born at the château of Vroncourt (Haute-Marne) on the 29th of May 1830, the daughter of a serving-maid, Marianne Michel, and the son of the house, Étienne Charles Demahis. She was brought up by her father's parents, and received a liberal education. After her grandfather's death in 1850 she was trained to teach, but her refusal to acknowledge Napoleon III. prevented her from serving in a state school. She found her way in 1866 to a school in the Montmartre quarter of Paris, where she threw herself ardently into works of charity and revolutionary politics. She became violently anti-Bonapartist, and is said to have meditated the assassination of Napoleon. During the siege of Paris she joined the ambulance service, and untiringly preached resistance to the Prussians. On the establishment of the Commune she joined the National Guard. She offered to shoot Thiers, and suggested the destruction of Paris by way of vengeance for its surrender. She was with the Communards who made their last stand in the cemetery of Montmartre, and was closely allied with Théodore Ferré, who was executed in November 1871. This ardent attachment was perhaps one of the sources of the exaltation which marked her career, and gave many handles to her enemies. When she was brought before the 6th council of war in December 1871 she defied her judges and defended the Commune. She was sent as a convict to New Caledonia, among her companions being Henri Rochefort, who remained her friend till the day of her death. The amnesty of 1880 found her revolutionary ardour unchanged. She travelled throughout France, preaching revolution, and in 1883 she led a Paris mob which pillaged a baker's shop. For this she was condemned to six years' imprisonment, but was released in 1886, at the same time as Prince Kropotkin and other prominent anarchists. After a short period of freedom she was again arrested for making inflammatory speeches. She was soon liberated, but, hearing that her enemies hoped to intern her in a lunatic asylum, she fled to England. She returned to France in 1895, and in 1902 was back in London. She was touring France and lecturing on behalf of anarchist propaganda when she died at Marseilles on the 10th of January 1905.

Her *Mémoires* (Paris, 1886) contain accounts of her trials. See also *La Bonne Louise* (Paris, 1906), by E. Girault.

MICHEL, FRANCISQUE XAVIER (1809–1887), French antiquary, was born at Lyons on the 18th of January 1809. He became known for his editions of French works of the middle ages, and the French Government, recognizing their value, sent him to England (1833) and Scotland (1837) to continue his researches there. In 1839 he was appointed professor of foreign literature in the *Faculté des lettres* at Bordeaux. Between 1834 and 1842 he published editions of a large number of works written between the eleventh and fourteenth centuries in French, English and Saxon, including the *Roman de la rose* and the *Chanson de Roland*. Subsequently he published French translations of Goldsmith, Sterne, Shakespeare and Tennyson. He died in Paris on the 18th of May 1887.

His original works include *Histoire des races maudites de la France et de l'Espagne* (1847); *Recherches sur le commerce pendant le moyen âge* (1852–1854); *Les Écossais en France et les français en Écosse* (1862); *Études de philologie comparée sur l'argot* (1856); *Le Pays basque* (1857); *Histoire du commerce et de la navigation à Bordeaux* (1867–1871); and, in conjunction with Edouard Fournier, *Histoire des hôtelleries, cabarets, hôtels garnis* (1851–1854).

MICHELANGELO (MICHELAGNIOLO BUONARROTI) (1475–1564), the most famous of the great Florentine artists of the Renaissance, was the son of Ludovico Buonarroti, a poor gentleman of that city, and of his wife Francesca dei Neri. The Buonarroti Simoni were an old and pure Florentine stock of the Guelf faction: in the days of Michelangelo's fame a connexion of the family with the counts of Canossa was imagined and admitted on both sides, but has no foundation in fact. Ludovico was barely able to live on the income of his estate, but made it his boast that he had never stooped to add to it by mercantile or mechanical pursuits. The favour of the Medici procured him temporary employment in minor offices of state, among them that of podestà or resident magistrate for six months, from the autumn of 1474, at Castello di Chiusi and Caprese in the Casentino. At Caprese, on the 6th of March 1475, his second son Michelagniolo or Michelangelo was born. Immediately afterwards the family returned to Florence, and the child was put to nurse with a marble-worker's wife of Settignano. His mother's health had already, it would seem, begun to fail; at all events in a few years from this time, after she had borne her husband three more sons, she died. While still a young boy Michelangelo determined, in spite of his father's opposition, to be an artist. He had sucked in the passion, as he himself used to say, with his foster-mother's milk. After a sharp struggle his stubborn will overcome his father's pride of gentility, and at thirteen he got himself articled as a paid assistant in the workshop of the brothers Ghirlandaio Domenico Ghirlandaio, bred a jeweller, had become by this time the foremost painter of Florence. In his service the young Michelangelo laid the foundations of that skill in fresco with which twenty years afterwards he confounded his detractors at Rome. He studied also, like all the Florentine artists of that age, in the Brancacci chapel, where the frescoes of Masaccio, painted some sixty years before, still victoriously held their own; and here, in reply, to a taunt he had flung at a fellow-student, Torrigiano, he received the blow on the nose which disfigured him to his dying day.

Though Michelangelo's earliest studies were directed towards painting, he was by nature and predilection much more inclined to sculpture. In that art he presently received encouragement and training under the eye of an illustrious patron, Lorenzo dei Medici. On the recommendation, it is said, of Ghirlandaio, he was transferred, before the term of his apprenticeship as a painter had expired, to the school of sculpture established by Lorenzo in the Medici gardens. Here he could learn to match himself against his great predecessor, Donatello, one of whose pupils and assistants, the aged Bertoldo, was director of the school, and to compare the works of that master and his Tuscan contemporaries with the antiques collected for the instruction of the scholars. Here, too, he could listen to discourses on Platonism, and steep himself in the doctrines of an enthusiastic philosophy which sought to reconcile with Christian faith the lore and the doctrines of the Academy. Michelangelo remained a Christian Platonist to the end of his days; he was also from his youth up a devoted student of Dante. His powers of mind and hand soon attracted attention, and secured him the regard and favour of his patrons in spite of his rugged exterior and scornful unsociable temper.

Michelangelo had been attached to the school and household of the Medici for barely three years when, in 1492, his great patron Lorenzo died. Lorenzo's son Piero dei Medici inherited the position but not the qualities of his father; Florence soon chafed under his authority; and towards the autumn of 1494 it became apparent that disaster was impending over him and his adherents. Michelangelo was constitutionally subject to dark and sudden presentiments: one such seized him now, and without awaiting the popular outbreak, which soon followed, he took horse with two companions and fled to Bologna. There, being now in his twentieth year, he was received with kindness by a member of the Aldovrandi family, on whose commission he executed two figures of saints and one of an angel for the shrine of St Dominic in the church of St Petronius. After about a year, work at Bologna failing, and his name having been included in his absence on the list of artists appointed to provide a new hall of assembly for the great council of Florence, Michelangelo returned home. The strange theocracy established by Savonarola was now in force, and the whole character of civic life at Florence was for the time being changed. The influence of the fervent Dominican upon the mind and character of the young Michelangelo became as profound as that of the Platonists and of Dante. He was not left without employment. He found a friend in another Lorenzo, the son of Pierfrancesco dei Medici, for whom he at this time executed a statue of the boy St John. Having also carved a recumbent Cupid in imitation of the antique, it was suggested to him by the same patron that it should be so tinted and treated as to look like a real antique, and sold accordingly. Without increasing the price he put upon the work, Michelangelo for amusement lent himself to the counterfeit, and the piece was then actually sold for a large sum, as a genuine work of antiquity, to a Roman collector, Raffaelle Riario, cardinal di San Giorgio; the dealer appropriating the profits. When the cardinal discovered the fraud he caused the dealer to refund; but as to Michelangelo himself, it was represented to the young sculptor that if he went to Rome the amateur who had just involuntarily paid so high a tribute to his skill would certainly befriend him. He set forth accordingly, and arrived at Rome for the first time at the end of June 1496. Such hopes as he may have entertained of countenance from the cardinal di San Giorgio were quickly dispelled. Neither did the banished Piero dei Medici, who also was now living at Rome, do anything to help him. On the other hand Michelangelo won the favour of a Roman nobleman, Jacopo Galli, and through him of the French cardinal Jean de Villiers de la Grolaie, abbot of St Denis. From the former he received a commission for a "Cupid" and a "Bacchus," from the latter for a "Pietà" or "Mary lamenting over the body of Christ"—works of which the two last named only are preserved. Equal originality of conception and magnificence of technical execution mark the two contrasted subjects—one as noble and the other as nearly ignoble as anything Michelangelo ever did—of the mother with the dead son on her lap, indicating with a contained but eloquent gesture of her left hand a tragedy too great for outcries, and the titubant sensual young wine-god (a condition in which ancient art would never have exhibited the god himself, but only his satellites).

Michelangelo's stay in Rome at this time lasted five years—from the summer of 1496 till that of 1501. The interval had been one of extreme political distraction at Florence. The excitement of the French invasion, the mystic and ascetic regimen of Savonarola, the reaction which led to his overthrow, and finally the external wars and internal dissidences which preceded a new settlement, had all created an atmosphere most unfavourable to art. Nevertheless Ludovico Buonarroti, who in the troubles of 1494 had lost a small permanent appointment he held in the customs, and had come to regard his son Michelangelo as the mainstay of his house, had been repeatedly urging him to come home. A spirit of family duty and family pride was the ruling principle in all Michelangelo's conduct. During the best years of his life he submitted himself sternly and without a murmur to pinching hardship and almost superhuman labour for the sake of his father and brothers, who were ever selfishly ready to be fed and helped by him. Having now, after an illness, come home in 1501, Michelangelo was requested by the cardinal Francesco Piccolomini to adorn with a number of sculptured figures a shrine already begun in the cathedral of Siena in honour of the most distinguished member of his house, Pope Pius II. Four only of these figures were ever executed, and those not apparently, or only in small part, by the master's hand. A work of greater interest in Florence itself had diverted him from his engagement to his Sienese patrons. This was the execution of the famous colossal statue of David, popularly known as "the Giant." It was carved out of a huge block of marble on which another sculptor, Agostino d'Antonio, had begun unsuccessfully to work forty years before, and which had been lying idle ever since. Michelangelo had here a difficult problem before him. Without much regard to the traditional treatment of the subject or the historical character of his hero, he carved out of the vast but cramped mass of material an adolescent, frowning colossus, tensely watchful and self-balanced in preparation for his great action. The result amazed every beholder by its freedom and science of execution and its victorious energy of expression. All the best artists of Florence were called in council to determine on what site it should be set up, and after much debate the terrace of the palace of the Signory was chosen, in preference to the neighbouring Loggia dei Lanzi. Here accordingly the colossal "David" of Michelangelo took, in the month of May 1504, the place which it continued to hold until in 1882 it was removed for the sake of protection to a hall in the Academy of Fine Arts, where it inevitably looks crushed and cabined. Other works of sculpture belong to the same period: among them a second "David," in bronze and on a smaller scale, commissioned by the maréchal Pierre Rohan and left by the young master to be finished by Benedetto da Rovezzano, who despatched it to France in 1508; a great rough-hewn "St Matthew" begun but never completed for the cathedral of Florence; a "Madonna and Child" executed on the commission of a merchant of Bruges; and two unfinished bas-reliefs of the same subject.

Neither was Michelangelo idle at the same time as a painter. Leaving disputed works for the moment out of sight, he in these days at any rate painted for his and Raphael's common patron, Angelo Doni, the "Holy Family" now in the Uffizi at Florence. In the autumn of 1504, the year of the completion of the "David," he received from the Florentine state a commission for a work of monumental painting on a heroic scale. Leonardo da Vinci had been for some months engaged on his great cartoon of the "Battle of Anghiari," to be painted on the wall of the great hall of the municipal council. The gonfaloniere Piero Soderini now procured for Michelangelo the commission to design a companion work. Michelangelo chose an incident at the battle of Cascina during the Pisan war of 1364, when the Florentine soldiery had been surprised by the enemy in the act of bathing. He dashed at the task with his accustomed fiery energy, and had carried a great part of the cartoon to completion when, in the early spring of 1505, he broke off the work in order to obey a call to Rome which reached him from Pope Julius II. His unfinished cartoon, in its power over the varieties and contrasts of energetic and vitally significant action, showed how greatly Michelangelo had profited by the example of his elder rival, Leonardo, little as, personally, he yielded to Leonardo's charm or could bring himself to respond to his courtesy. The work of Michelangelo's youth is for the most part comparatively tranquil in character. His early sculpture, showing a degree of science and perfection unequalled since the antique, has also something of the antique serenity. It bears strongly the stamp of intellectual research, but not by any means that of storm or strain. In the cartoon of the "Bathers" the qualities afterwards proverbially associated with Michelangelo—his *furia*, his *terribilità*, the tempest and hurricane of the spirit which accompanied his unequalled technical mastery and knowledge—first found expression.

With Michelangelo's departure to Rome early in 1505 the first part of his artistic career may be said to end. It will be convenient here to recapitulate its principal results in sculpture and painting, both those preserved and those recorded but lost.

Sculpture.—*Florence, 1489–1494.*—"Head of a Faun," marble; lost. Condivi describes Michelangelo's first essay in sculpture as a head of an aged faun with a front tooth knocked out, this latter point having been an afterthought suggested by Lorenzo dei Medici. The head is sometimes identified with one in the National Museum at Florence, which however bears no marks of Michelangelo's early style and is in all probability spurious.—"Madonna seated on a Step," bronze; Casa Buonarroti, Florence. This bas-relief, executed in imitation of the technical style of Donatello, is a genuine example of Michelangelo's early work in the Medicean school under Bertoldo.—"Centauromachia," marble; Casa Buonarroti. A fine and genuine work in full relief, of probably somewhat later date than the last-mentioned. The subject occurs often in ancient sarcophagus reliefs: Michelangelo has followed the antique in his conception and treatment of the nude, but the arrangement of the subject is his own.

Bologna, 1494–1495.—Statuettes of "St Petronius," "St Proculus," and a "Kneeling Angel," marble; part of the decorations of the shrine of St Dominic in the church of that saint at Bologna: the style of all three much influenced by the work of Jacopo della Quercia in the same church; the attitude of the kneeling angel with the candelabrum imitated from an ancient bas-relief.

Florence, 1495–1496.—"St John in the Wilderness," executed for Lorenzo di Pierfrancesco dei Medici, marble; probably lost. Declared in 1874 to have been found again in the possession of Count Gualandi-Rossalmini at Pisa. Vehement and prolonged discussion arose as to the authenticity of this newly-found S. Giovannino, and at last it was bought for the Berlin Museum, where its genuineness is still stoutly maintained. But the finicking and affected elegance of the conception denote a different temperament from Michelangelo's and probably a later date. With this figure must be given up also the restoration of an antique group of "Bacchus and Ampelus" at the Uffizi, which is clearly by the same hand and is claimed also as an early work of Michelangelo.—"Recumbent Cupid," bought by the cardinal San Giorgio as an antique, marble; lost. The attempts to recognize it in certain extant copies or servile imitations of the antique, especially one now at Turin, must be held mistaken.

Rome, 1495–1501.—"Virgin lamenting the dead Christ," commissioned by the abbot de la Grolaie; marble, St Peter's, Rome.—"Bacchus and young Faun," commissioned by Jacopo Galli; marble, National Museum, Florence. (Of these two masterpieces of Michelangelo's youth enough has been said above).—"Cupid," commissioned by the abbot de la Grolaie; marble; lost; has been commonly identified as the "Kneeling Cupid" of the Victoria and Albert Museum, but this, if by Michelangelo at all, which is not quite certain, must in all likelihood belong to a later time.

Florence, 1501–1506.—"Five Saints, in niches decorating the shrine of Pius II.," commissioned by the Piccolomini family; marble; cathedral of Siena. The contract for the sculptured decoration of this shrine was one of those which the pressure of other work prevented the artist from ever taking seriously in hand. Of the five saints in niches, traditionally reputed to be his work, the St Peter alone shows any clear marks of his style; the other four were probably designed, and certainly carried out, by weaker hands.—"David" (the "Gigante"), commissioned for the city of Florence by Piero Soderini; marble; Florence Academy. Besides what has been said above, it has only to be added that a wax model in the Casa Buonarroti, showing nearly the same design with a different movement of the legs, is probably Michelangelo's original sketch for the subject. "David," commissioned by Pierre Rohan; bronze, lost; a clay model in the National Museum, Florence, may probably be a sketch for it; more than one bronze has been brought forward with claims to be the original, but none has stood the test of criticism. "Virgin and Child," commissioned for Taddeo Taddei; circular relief, unfinished, marble; London, Royal Academy. The motive of the Christ-child frightened by the flutterings of the bird held out by St John is the most playful in all Michelangelo's work; the whole design shows the influence of Leonardo in his gentler, as much as the cartoon of the "Bathers" shows it in his more violent, moods. "Virgin and Child with St John," commissioned by Bartolommeo Pitti; nearly circular relief, unfinished, marble; Florence, National Museum: a more tranquil and very charming presentment. "Madonna and Child," sold to the Mouscron family of Bruges (known in Italy as Moscheroni), and by them presented to the church of Notre Dame in that city; group in the round, marble; church of Notre Dame, Bruges. A meditative seated Virgin with upright head, the naked child seated between her knees, his smoothly rounded form in strong contrast with her complicated draperies. "St Matthew": one of a set of twelve statues of Apostles commissioned by the consuls of the Arte della Lana for the cathedral at Florence; marble; National Museum, Florence. Unfinished (only roughly blocked out), the other figures of the set never having been so much as begun; the contract was signed in 1503 and cancelled in 1505. There is an early drawing by Raphael from this statue.

Painting.—"Holy Family," painted for Angelo Doni; tempera, circular: Florence, Uffizi. The only perfectly well-attested panel painting of Michelangelo which exists. His love of restless and somewhat strained actions is illustrated by the gesture of the Madonna, who kneels on the ground holding up the child on her right shoulder; his love of the nude by the introduction (wherein he follows Luca Signorelli) of some otherwise purposeless undraped figures in the background. "Virgin and Child with Four Angels"; tempera; National Gallery, London. This unfinished painting, strongly marked by the influence of Michelangelo in his work at this period, has been confidently claimed for him, but lacks his strength and mastery, and is far more probably the work of his imitator and intimate associate, Francesco Granacci. "Cartoon of the Bathers"; lost and utterly perished. The only authentic records of it are contained in a few early engravings by Marcantonio and Agostino Veneziano and a certain number of sketches and studies by the master himself, chiefly at the Albertina, Vienna, the British Museum and the University Galleries, Oxford. An elaborate drawing of many figures at Holkham Hall, well known and often engraved, seems to be a later *cento* destitute of real authority.

Michelangelo had not been long in Rome before Pope Julius devised fit employment for him. That capacious and headstrong spirit, on fire with great enterprises, had conceived the idea of a sepulchral monument to commemorate his glory when he should be dead, and to be executed according to his own plans while he was still living. He entrusted this congenial task to Michelangelo. The design being approved, the artist spent the winter of 1505–1506 at the quarries of Carrara, superintending the excavation and shipment of the necessary marbles. In the spring he returned to Rome, and when the marbles arrived fell to with all his energy at the preparations for the work. For a while the pope followed their progress eagerly, and was all kindness to the young sculptor. But presently his disposition changed. In Michelangelo's absence an artist who was no friend of his, Bramante of Urbino, had been selected by Julius to carry out a new architectural scheme, commensurate with the usual vastness of his conceptions, viz. the rebuilding of St Peter's church. To the influence and the malice of Bramante Michelangelo attributed the unwelcome invitation he now received to interrupt the great work of sculpture which he had just begun in order to decorate the Sixtine chapel with frescoes. Soon, however, schemes of war and conquest interposed to divert the thoughts of Julius, not from the progress of his own monument merely, but from artistic enterprises altogether. One day Michelangelo heard him say at table to his jeweller that he meant to spend no more money on pebbles, either small or great. To add to the artist's discomfiture, when he went to apply in person for payments due, he was first put off from day to day, and at last actually with scant courtesy dismissed. At this his dark mood got the mastery of him. Convinced that not his employment only but his life was threatened, he suddenly took horse and left Rome, and before the messengers of the pope could overtake him was safe on Florentine territory. Michelangelo's flight took place in April 1506. Once among his own people, he turned a deaf ear to all overtures made from Rome for his return, and stayed throughout the summer at Florence, how occupied we are not distinctly informed, but apparently, among other things, on the continuation of his great battle cartoon.

During the same summer Julius planned and executed the victorious military campaign which ended with his unopposed entry at the head of his army into Bologna. Thither, under strict safe-conduct and promises of renewed favour, Michelangelo was at last persuaded to betake himself. Julius received the truant artist kindly, as indeed between these two volcanic natures there existed a natural affinity, and ordered of him his own colossal likeness in bronze, to be set up, as a symbol of his conquering authority, over the principal entrance of the church of St Petronius. For the next fifteen months Michelangelo devoted his whole strength to this new task. The price at which he undertook it left him, as it turned out, hardly any margin to subsist on. Moreover in the technical art of metal casting he was inexperienced, and an assistant whom he had summoned from Florence proved insubordinate and had to be dismissed. Nevertheless his genius prevailed over every hardship and difficulty, and on the 21st of February 1508 the majestic bronze colossus of the seated pope, robed and mitred, with one hand grasping the keys and the other extended in a gesture of benediction and command, was duly raised to its station over the church porch. Three years later it was destroyed in a revolution. The people of Bologna rose against the authority of Julius; his delegates and partisans were cast out, and his effigy hurled from its place. The work of Michelangelo, after being trailed in derision through the streets, was broken up and its fragments cast into the furnace.

Meanwhile the artist himself, as soon as his work was done, had followed his reconciled master back to Rome. The task that here awaited him, however, was after all not the resumption of the papal monument, but the execution of the series of paintings in the Sixtine chapel which had been mooted before his departure. Painting, he always averred, was not his business; he was aware of his enemy's hopes that a great enterprise in fresco-painting would prove beyond his powers; and he entered with misgiving and reluctance upon his new undertaking. Destiny, however, so ruled that the work thus thrust upon him remains his chief title to glory. His history is one of indomitable will and almost superhuman energy, yet of will that hardly ever had its way, and of energy continually at war with circumstance. The only work which in all his life he was able to complete as he had conceived it was this of the decoration of the Sixtine ceiling. The pope had at first desired a scheme including figures of the twelve apostles only. Michelangelo began accordingly, but could rest content with nought so meagre, and soon proposed instead a design of many hundred figures embodying the story of Genesis from the Creation to the Flood, with accessory personages of prophets and sibyls dreaming on the new dispensation to come, and, in addition, those of the forefathers of Christ. The whole was to be enclosed and divided by an elaborate framework of painted architecture, with a multitude of nameless human shapes supporting its several members or reposing among them—shapes mediating, as it were, between the features of the inanimate framework and those of the great dramatic and prophetic scenes themselves. The pope bade the artist do as he pleased. By May 1508 the preparations in the chapel had been completed and the work begun. Later in the same year Michelangelo summoned a number of assistant painters from Florence. Trained in the traditions of the earlier Florentine school, they were unable, it seems, to interpret Michelangelo's designs in fresco either with sufficient freedom or sufficient uniformity of style to satisfy him. At any rate he soon dismissed them, and carried out the remainder of his colossal task alone, except for the necessary amount of purely mechanical and subordinate help. The physical conditions of prolonged work, face upwards, upon this vast expanse of ceiling were adverse and trying in the extreme. After four and a half years of toil the task was accomplished. Michelangelo had during its progress been harassed alike by delays of payment and by hostile intrigue, his ill-wishers casting doubts on his capacity, and vaunting the superior powers of Raphael. That gentle spirit would by nature have been no man's enemy, but unluckily Michelangelo's moody, self-concentrated temper prevented the two artists being on terms of amity such as might have stopped the mouths of mischief-makers. Absolute need of funds for the furtherance of the undertaking constrained him at one moment to break off work and pursue his inconsiderate patron as far as Bologna. This was between September 1510, by which time the whole of the great series of subjects along the centre of the vault were completed, and January 1511, when the master set to work again and began filling the complicated lateral spaces of his decorative scheme.

The main field of the Sixtine ceiling—in form a depressed barrel vault—is divided in Michelangelo's scheme into four larger, alternating with five smaller fields. The following is the order of the subjects depicted in them: (1) the dividing of the light from the darkness; (2) the creation of sun, moon and stars; (3) the creation of the waters; (4) the creation of man; (5) the creation of woman; (6) the temptation and expulsion; (7) the sacrifice of Noah; (8) the deluge; (9) the drunkenness of Noah. The figures in the last three of these scenes are on a smaller scale than those in the first six. In numbers 1, 3, 5, 7 and 9 the field of the picture is reduced by the encroachments of the architectural framework with its seated pairs of supporters, commonly known as "Slaves" or "Atlases." Flanking these smaller compositions, along the lateral spaces between the crown of the vault and the walls on either side, are seated figures of prophets and sibyls alternately; two other prophets are introduced at each extremity of the series—making seven prophets and five sibyls in all. In the triangles to right and left of the prophets at the two extremities are the death of Goliath, the death of Holofernes, the brazen serpent and the punishment of Haman. In the twelve lunettes above the windows are groups of the ancestors of Christ, their names designated by inscriptions, and in the twelve triangles above them (between the prophets and sibyls) other kindred groups crouched or sitting. These last are all shown in relatively simple human actions and household relations, heightened but not falsified by the artist's genius, and rising into majestic significance from roots deep in daily human nature. The work represents all the powers of Michelangelo at their best. Disdaining all the accessory allurements of the painter's art, he has concentrated himself upon the exclusive delineation of the human form and face at their highest power. His imagination has conceived, and his knowledge and certainty of hand have enabled him to realize, attitudes and combinations of unmatched variety and grandeur, and countenances of unmatched expressiveness and power. But he has not trusted, as he came later to trust, to science and acquired knowledge merely; neither do his personages, so far as they did afterwards, transcend human possibility or leave the facts of actual life behind them. The profoundest knowledge and the most searching realism serve to embody all this inspiration and sustain all this sublimity; the sublimity, moreover is combined with the noblest elements of grace and even of tenderness. As for the intellectual meanings of his vast design, over and above those which reveal themselves at a first glance or by a bare description, they are from the nature of the case inexhaustible, and can never be perfectly defined. Whatever the soul of this great Florentine, the spiritual heir of Dante, with the Christianity of the middle ages not shaken in his mind, but expanded and transcendentalized, by the knowledge and love of Plato;—whatever the soul of such a man, full of suppressed tenderness and righteous indignation, and of anxious questionings of coming fate could conceive—that Michelangelo has expressed or shadowed forth in this great and significant scheme of paintings. The powers of the artist seem to have expanded with the progress of his work. He seems to have begun (as the spectator entering the chapel has to begin) with what is chronologically the last subject of the series, the drunkenness of Noah, and to have worked backwards, increasing the scale of his figures for their better effect from the fourth subject (the Temptation and Expulsion), and rising in ascending scale of majesty through the successive acts of creation from the last to the first.

The Sixtine chapel was no sooner completed than Michelangelo resumed work upon the marbles for the monument of Julius. But four months only had passed when Julius died. His heirs immediately entered (in the summer of 1513) into a new contract with Michelangelo for the execution of the monument on a reduced scale. What the precise nature and extent of the original design had been we do not know, only that the monument was to be detached from the wall, and to stand four-square and free—a thing hitherto unknown in Renaissance sepulchral architecture—in one of the chapels of St Peter's. But the new design was extensive and magnificent enough. It was to consist of a great three-sided structure, two courses high, projecting from the church wall, and decorated on its three unattached sides with statues. On the upper course was to be placed the colossal recumbent figures of the pope, with a vision of the Virgin and Child above him, angels mourning at the sides, and prophetic and allegoric personages at the angles—sixteen figures in all. The lower course was to be enriched with twenty-four figures in niches and on projecting pedestals: in the niches, Victories; in front of terminal pilasters between them, slaves or captives denoting, it would seem, either conquered provinces or arts and sciences in bondage after their patron's death. A much injured and not indisputable sketch by the master at Berlin, with a copy of the same by Sacchetti, are supposed to show the design at this stage of its reduction. The entire work was to be completed in nine years' time. During the next three years, it would seem, Michelangelo brought to completion three at least of the promised figures, for which the blocks had reached Rome from Carrara as early as July 1508; and they are among the most famous of all existing works of the sculptor's art—namely, the "Moses," now in the church of S. Pietro in Vincoli at Rome and the two "Slaves" at the Louvre.

The "Moses," originally intended for one of the angles of the upper course, is now placed at the level of the eye, in the centre of the principal face of the monument as it was at last finished, on a deplorably reduced and altered scale, by Michelangelo and his assistants in his old age. The prophet, supposed to have just come down from Mount Sinai and found the Israelites worshipping the golden calf, sits, heavily bearded and draped, with only his right arm bare, his left foot drawn back, his head raised and turned to the left, his left hand laid on his lap and his right grasping the tables of the law—an incarnation of majestic indignation and menace. The work, except in one or two places, is of the utmost finish, and the statue looks like one of the prophets of the Sixtine ceiling done in marble. The "Slaves" at the Louvre are youthful male figures of equally perfect execution, nude but for the band which passes over the breast of one and the right leg of the other. One, with his left hand raised to his head and his right pressed to his bosom, his eyes almost closed, seems succumbing to the agonies of death; the other, with his arms bound behind his back, looks upward still hopelessly struggling. All three of these figures were finished between 1513 and 1516.

By 1516 Michelangelo's evil star was again in the ascendant. Julius II. had been succeeded on the papal throne by Cardinal Giovanni de' Medici under the title of Leo X. The Medici, too, had about the same time by force and fraud re-established their sway in Florence, overthrowing the free institutions that had prevailed there since the days of Savonarola. Now, on the one hand, this family were the hereditary friends and patrons of Michelangelo; on the other hand he was a patriotic son of republican Florence; so that henceforward his personal allegiance and his political sympathies were in conflict. Over much of his art, as has been thought, the pain and perplexity of this conflict have cast their shadow. For the present the consequence to him of the rise to power of the Medici was a fresh interruption of his cherished work on the tomb of Julius. Leo X. and his kinsmen were full of a vast new scheme for the enrichment and adornment of the façade of their own family church of San Lorenzo in Florence. Michelangelo, carried away by the idea and forgetful of his other still great and onerous task, offered his services for the new façade. They were eagerly accepted, although for a moment the idea had been entertained of entrusting the work to Leonardo da Vinci. The heirs of Julius on their part showed an accommodating temper, and at the request of Leo allowed their three-years'-old contract to be cancelled in favour of another, whereby the scale and sculptured decorations of the Julian monument were again to be reduced by nearly a half. Michelangelo soon produced for the San Lorenzo façade a design of combined sculpture and architecture as splendid and ambitious in its way as had been that for the original monument of Julius. The contract was signed in January 1518, and the artist went to Carrara to superintend the excavation of the marbles.

Michelangelo was now in his forty-fourth year. Though half his life was yet to come, yet its best days had, as it proved, been spent. All the hindrances which he had encountered hitherto were as nothing to those which began to beset him now. For the supply of materials for the façade of San Lorenzo he had set a firm of masons to work, and had himself, it seems, entered into a kind of partnership with them, at Carrara, where he knew the quarries well, and where the industry was hereditary and well understood. When all was well in progress there under his own eye, reasons of state induced the Medici and the Florentine magistracy to bid him resort instead to certain new quarries at Pietrasanta, near Serravalle in the territory of Florence. Hither, to the disgust of his old clients at Carrara and to his own, Michelangelo accordingly had to transfer the scene of his labours. Presently he found himself so impeded and enraged by the mechanical difficulties of raising and transporting the marbles, and by the disloyalty and incompetence of those with whom he had to deal, that he was fain to throw up the commission altogether. The contracts for the façade of San Lorenzo were rescinded in March 1518, and the whole magnificent scheme came to nothing. Michelangelo then returned to Florence, where proposals of work poured in on him from many quarters. The king of France desired something from his hand to place beside the two pictures he possessed by Raphael. The authorities of Bologna wanted him to design a façade for their church of St Petronius; those of Genoa to cast a statue in bronze of their great commander, Andrea Doria. Cardinal Grimani begged hard for any picture or statue he might have to spare; other amateurs importuned him for so much as a pencil drawing or sketch. Lastly his friend and partisan Sebastian del Piombo at Rome, ever eager to keep up the feud between the followers of Michelangelo and those of Raphael, besought him on Raphael's death to return at once to Rome, and take out of the hands of the dead master's pupils the work of painting still remaining to be done in the Vatican chambers. Michelangelo complied with none of these requests. All that we certainly know of his doing between 1518 and 1522 is the blocking out in the rough of four more of the "Slaves" for the tomb of Julius, and carrying out a commission, which he had received from three citizens of Rome as early as 1514, for a statue of the risen Christ. The roughed-out "Slaves" now stand immured in a grotto in the Boboli Gardens, Florence; the Christ, practically finished by the master but with the last touches added by pupils, stands in the church, for which it was destined, of Sta Maria sopra Minerva at Rome; there is little in it either of devotional spirit or imaginative power, although, in those parts which Michelangelo himself finished, there is extreme accomplishment of design and workmanship.

The next twelve years of Michelangelo's life (1522–1534) were spent at Florence, and again employed principally in the service of his capricious and uncongenial patrons—the Medici. The plan of a great group of monuments to deceased members of this family, to be set up in a new sacristy or mortuary chapel in San Lorenzo, was first broached to Michelangelo in 1520 by Cardinal Giulio de' Medici. No practical impulse, however was given to the work until Giulio, after the death of Leo X and the brief pontificate of the puritanical and iconoclastic Adrian VI., had in his turn become pope in 1523 under the title of Clement VII. Even then the impulse was a wavering one. First Clement proposed to associate another artist Sansovino, with Michelangelo in his task. This proposal being on Michelangelo's peremptory demand abandoned, Clement next distracted the artist with an order for a new architectural design—that, namely, for the proposed Medicean or "Laurentian" library. When at last after many changes of scope and scheme the plans for the sepulchral chapel or "Sagrestìa nuova" took shape, they did not include, as had been at first intended memorials to the founders of the house's greatness, Cosimo (*pater patriae*) and Lorenzo the Magnificent, or even to Pope Leo X. himself, but only to two younger members of the house lately deceased, Giuliano, duke of Nemours, and Lorenzo duke of Urbino. Michelangelo brooded long over various designs for this work, and was still engaged on its execution—his time being partly also taken up by the building-plans for the Medicean library—when political revolutions interposed to divert his industry. In 1527 came to pass the sack of Rome by the Austrians, and the apparently irretrievable ruin of Pope Clement. The Florentines seized the occasion to expel the Medici from their city, and set up a free republican government once more. Naturally no more funds for the works in San Lorenzo were forthcoming, and Michelangelo, on the invitation of the new signory, occupied himself for a while with design for a group of Hercules and Cacus, and another of Samson and the Philistines—the latter to be wrought out of a block of marble which had been rough-hewn already for another purpose by Baccio Bandinelli. Soon, however, he was called to help in defending the city itself from danger. Clement and his enemy Charles V. having become reconciled, both alike were now bent on bringing Florence again under the rule of the Medici. In view of the approaching siege, Michelangelo was appointed engineer-in-chief of the fortifications. He spent the early summer of 1529 in strengthening the defences of San Miniato; from July to September he was absent on a diplomatic mission to Ferrara and Venice. Returning in the middle of the latter month, he found the cause of Florence hopeless from internal treachery and from the overwhelming strength of her enemies. One of his dark seizures overcame him, and he departed again suddenly for Venice. There for a while he remained, negotiating for a future residence in France. Then, while the siege was still in progress, he returned once more to Florence; but in the final death-struggle of her liberties he bore no part. When in 1530 the city submitted to her conquerors, no mercy was shown to most of those who had taken part in her defence. Michelangelo believed himself in danger with the rest, but on the intervention of Baccio Valori he was presently taken back into favour and employment by Pope Clement. For four years more he continued to work at intervals on the completion of the Medici monuments, with the help from 1532 of Giovanni Montorsoli and other pupils, and on the building of the Laurentian library. In 1531 he suffered a severe illness; in 1532 he made a long stay at Rome, and entered upon yet another contract for the completion of the Julian monument, to be reduced now to a still more shrunken scale and to be placed not in St Peter's but in the church of San Pietro in Vincoli. In the autumn of 1534 he left Florence for good. What remained to be done in the Medici chapel was done by pupils, and the chapel was not finally opened to view until 1545.

The statues of the Medici monument take rank beside the "Moses" and the "Slaves" as the finest work of Michelangelo's central time in sculpture. They consist of a Madonna and Child and of the two famous monumental groups, each composed of an armed and seated portrait-statue in a niche, with two emblematic figures reclining on each side of a sarcophagus below. The "Madonna and Child" (left unfinished because the marble was short in bulk) combines astonishingly the divers qualities of realistic motive and natural animation with learned complexity of design and imposing majesty of effect. It was set up finally—not at all in accordance with the artist's first intention—against a blank wall of the chapel, and flanked at wide intervals by statues of Sts Cosmo and Damian, the work of pupils. The portraits are treated not realistically but typically. In that of Lorenzo seems to be typified the mood of crafty brooding and concentrated inward thought; in that of Giuliano, the type of alert and confident practical survey immediately preceding action. To this contrast of the meditative and active characters corresponds a contrast in the emblematic groups accompanying the portraits. At the feet of the duke Giuliano recline the shapes of "Night" and "Day"—the former a female, the latter a male, personification; the former sunk in an attitude of deep but uneasy slumber, the latter (whose head and face are merely blocked out of the marble) lifting himself in one of wrathful and disturbed awakening. But for Michelangelo's unfailing grandeur of style, and for the sense which his works convey of a compulsive heat and tempest of thought and feeling in the spirit that thus conceived them, both these attitudes might be charged with extravagance. As grand, but far less violent, are those of the two companion figures that recline between sleep and waking on the sarcophagus of the pensive Lorenzo. Of these, the male figure is known as "Evening," the female as "Morning" (*Crepusculo* and *Aurora*). In Michelangelo's original idea, partly founded on antique precedent in pedimental and sarcophagus groups, figures of "Earth" and "Heaven" were to be associated with those of "Night" and "Day" on the monument of Giuliano, and others—no doubt of a corresponding nature, with those of the Morning and Evening Twilight on that of Lorenzo. These figures afterwards fell out of the scheme and the recesses designed for them remain empty. Michelangelo's obvious and fundamental idea was, as some words of his own record, to exhibit the elements and the powers of earth and heaven lamenting the death of the princes. River-gods were to recline on the broad bases at the foot of the monuments. These too are lacking. They were never finished, but a bronze cast from a small model of one of them, and the torso of a large model, have lately been identified, the former in the National Museum and the latter in the Academy at Florence.

Other works of 1522–1534.—"Victory" marble (National Museum, Florence). A youthful conqueror standing over a bearded enemy, whose shoulders he crushes down with his left knee. Fine and finished work: whether intended for one of the emblematic Victories of the Julian monument, or having some connexion with the "Hercules and Cacus" and "Samson and the Philistine," subjects undertaken for the Signory in 1528, must remain uncertain. For the former of these two subjects a wax model at the Victoria and Albert Museum, for the latter a plaster model at the Casa Buonarroti, are claimed, perhaps rightly, as original. "David" (formerly called "Apollo"), marble, unfinished (National Museum, Florence). Both the authenticity and the approximate date of this fine work are beyond doubt: of its origin and destination we are uninformed. "Crouching boy," marble, unfinished (the Hermitage, Petersburg). Another masterly sketch in marble; the seated lad stoops forward between his parted knees, having both hands occupied with his left foot; the figure blocked out of the marble, with the least possible sacrifice of the material; the subject and motive enigmatical. "Cupid," kneeling, apparently in the act of shooting downward with a bow, marble (Victoria and Albert Museum). Probably, but not quite certainly, authentic; if so, then of 1530 or thereabouts; its identification with the early Cupid done for Jacopo Galli at Rome in 1496 is untenable. "Leda," painting, done for the duke of Ferrara, but withheld because of the misconduct of his messenger, and given by the master to his pupil Antonio Mini in 1531; lost. A fine injured tempera painting of the subject in the store-rooms of the National Gallery in London may presumably be an early copy.

Michelangelo had fully purposed, as soon as he could get free of his task on the Medici tombs, to devote all his powers to the completion of the Julian monument in accordance with the new contract of 1532. But his intention was again frustrated. Pope Clement insisted that he must complete his decorations of the Sixtine Chapel by painting anew the great end wall above the altar, adorned until then by frescoes of Perugino. The subject chosen was the Last Judgment; and Michelangelo began to prepare sketches. In the autumn of 1534, in his sixtieth year, he settled finally, and for the remainder of his life, at Rome. Immediately afterwards Clement died, and was succeeded by a Farnese under the title of Paul III. Even more than his predecessor, Paul insisted on claiming the main services of Michelangelo for himself, and forced him to let all other engagements drift. For the first seven years after the artist's return to Rome, his time was principally taken up with the painting of the colossal and multitudinous "Last Judgment." This being completed in 1541, he was next compelled to undertake two more great frescoes—one of the Conversion of Paul and another of the Martyrdom of Peter—in a new chapel which the pope had caused to be built in the Vatican, and named after himself—Capella Paolina.

The fresco of the "Last Judgment" in the Sixtine Chapel is probably the most famous single picture in the world. In it Michelangelo shows more than ever the omnipotence of his artistic science, and the fiery daring of his conceptions. But the work, so far as its deplorably deteriorated condition admits comparison, is hardly comparable in the qualities of colour and decorative effect to the earlier and far more nobly inspired frescoes of the ceiling. It is to these and not to the "Last Judgment" that the student must turn if he would realize what is best and greatest in the art of Michelangelo.

The frescoes of the Pauline Chapel are on their part so injured as to be hardly susceptible of useful study or criticism. In their ruined state they bear evidence of the same tendencies that made the art of Michelangelo in its latest phase so dangerous an example to weaker men—the tendency, that is, to seek for unqualified energy and violence of action, both in place and out, for "terribleness" *quand même,* and to design actions not by help of direct study from nature, but by scientific deduction from the abstract laws of structure and movement. At best these frescoes can never have been happy examples of Michelangelo's art.

Other Work of the years 1534–1549. SCULPTURE.—During the fifteen years when Michelangelo was mainly engaged on these paintings, he had also at last been enabled to acquit himself, although in a manner that can have been satisfactory to none concerned, of his engagements to the heirs of Julius. Once more the influence of the pope had prevailed on them to accept a compromise altogether to their disadvantage. By a final contrast dated 1542, it was agreed that the "Moses" executed thirty years before, seated on a low plinth in a central recess, should be the chief figure of the new scheme; in niches at either side of him were to be standing figures of "Leah" and "Rachel." These Michelangelo himself executed hastily with the help of assistants. To pupils entirely was left the carrying out of the upper cornice, with the recumbent effigy of the pope occupying the centre of a weak and incongruous architectural scheme, a Madonna and Child in a niche above, and a prophet and a sibyl in recesses at either side. Meantime all idea of incorporating any of the "Slaves" in the new design had been abandoned. The master gave the two that had been finished in 1513–1516 to Robert Strozzi, who gave them to Francis I.; while the four that had been roughed out between 1518 and 1522 remained at Florence. "Brutus," marble (National Museum, Florence). Probably executed soon after 1539, in memory of the tyrannicide Lorenzino de' Medici. To the end of this period or to a year or two later belongs the infinitely pathetic unfinished sketch in marble of a life-size "*Pietà*" (Palazzo Rondini, Rome)—the mourning mother, standing on an elevation behind her son, holds his body upright in front of her by the shoulders. Still later, after 1550, is the more complicated and more finished group of the "*Pietà*," with the corpse of Christ collapsing in utter relaxation through the arms of those who try to uphold it: this Michelangelo destined for his own sepulchre; it stands now in the cathedral at Florence.

PAINTING.—"The Entombment of Christ" (National Gallery, London). This unfinished painting bears all the marks of Michelangelo's design, and must have been begun from a cartoon by him, probably of about 1535–1540. The touch of his own hand seems evident in some parts, particularly the body of Christ; other parts, in various degrees of incompletion, are apparently the work of various pupils or imitators.

For nearly all his great life-works mentioned above, preparatory sketches and studies by the master's hand exist. These, with a large number of other drawings, finished and unfinished, done for their own sakes and not for any ulterior use, are of infinite value and interest to the student. Michelangelo was the most learned and scientific as well as the most inspired and daring of draughtsmen, and from boyhood to extreme old age never ceased to practise with pen, chalk or pencil. He is said to have burned vast numbers of his drawings with his own hand and caused others to be burned by friends and pupils to whom he had given them; so that what we possess must be less than a tithe of what he executed. But there are some 250 genuine sheets—enough to let us follow and understand his modes of conceiving, preparing and maturing his designs at all periods of his life. They are scattered amongst various collections, chiefly public; those in England (at the British Museum, the University Galleries, Oxford, and the Royal Library, Windsor), are quite half the whole number; other important examples remain still at what was for centuries the home of his heirs, the Casa Buonarroti at Florence; others at the Uffizi, Florence; the Venice Academy; the Albertina, Vienna; the Louvre; the Condé Museum at Chantilly; the Berlin Museum; and, not least, the Teyler Museum at Haarlem. By means of these drawings and the many published facsimiles we are best able to trace the progress of the master's genius and its secrets. We see him diligently copying in youth from the frescoes of Giotto, Masaccio, and his own master Ghirlandaio. At this date his instrument was the pen only, used in a manner of hatching: sometimes extremely careful and close, at others fiercely bold and free, and in either case all his own. Sketches and studies thus drawn with the pen exist for the "David," the "Bathers Surprised," the accessory figures for the tomb of Julius as first conceived, and the great series of the Sixtine Chapel decorations. By, or even before, the date of the Sixtine Chapel, chalk, red or black, comes into use along with the pen, and many of the finest studies for the "Slaves" or "Atlases" and other decorative figures of the ceiling are in the latter material (many more studies are preserved for these subordinate figures than for the main compositions). After the Sixtine Chapel period the pen gives way to red or black chalk almost entirely. Sketches are rare for the great abortive scheme of the Julius monument; almost non-existent for the equally abortive San Lorenzo façade; fairly abundant for the various stages of the Medici monument scheme in its architectural parts, but not for the great figures. About the time of Michelangelo's final change of domicile from Florence to Rome (1532–1535) he began the practice of making highly finished and fully shaded drawings of classic or symbolic subjects in red or black chalk for presentation to his friends, especially to young Tommaso Cavalieri, the object of his passionate Platonic affection, from about 1532. The "Fall of Phaeton," the "Tityos," the "Ganymede," the "Men shooting at a Mark," are well-known examples; in this class of work the Windsor collection is far the richest. At the same time or soon afterwards, were produced drawings little less powerful and finished of Christian subjects, especially the "Crucifixion," "Entombment" and "Resurrection." Then comes the great fresco of the "Last Judgment," for which there exist both general sketches and particular studies. In the few extant drawings for the Cappella Paolina a faltering both of the imagination and of the hand become discernible. To the same or to still later years belong many beautiful but somewhat tentative drawings done either directly for, or nearly in the spirit of, the famous "Crucifixion" which he is recorded to have painted with so much devotion for Vittoria Colonna. About many of these, for all their intensity of feeling, there is a wavering touch betraying the approach of infirmity; so there is about many of the architectural studies done for the buildings of which he had charge in his last years at Rome; but signs of the old impressive power and penetration are not wanting in some even of the latest drawings that have come down to us.

During his later years the long-pent human elements of fervour and tenderness in Michelangelo's nature had found vent and utterance such as they had never found before. He had occasionally practised poetry in youth, and there are signs of some transient love-passages during his life at Bologna. But it was not until towards his sixtieth year that the springs of feeling were fairly opened in the heart of this solitary, this masterful and stern, life-wearied and labour-hardened man. About 1533–1534 we find him beginning to address impassioned sonnets—of which the sentiment is curiously comparable to that expressed in some of Shakespeare's—to a beautiful and gifted youth, the young Roman noble Tommaso Cavalieri. Soon afterwards he made the acquaintance of the pious, accomplished, and high-souled lady, Vittoria Colonna, widow of the Marquess Pescara. For ten years until her death, which happened in 1547, her friendship was the great solace of Michelangelo's life. On her, in all loyalty and reverence, he poured out all the treasures of his mind and all his imprisoned powers of tenderness and devotion. She was the chief inspirer of his poetry—of which, along with her praises, the main themes are the Christian religion, the joys of Platonic love, and the power and mysteries of art. Michelangelo's poetical style is strenuous and concentrated like the man. He wrote with labour and much self-correction; we seem to feel him flinging himself on the material of language with the same overwhelming energy and vehemence with which contemporaries describe him as flinging himself on the material of marble—the same impetuosity of temperament combined with the same fierce desire of perfection, but with far less either of innate instinct for the material or of trained mastery over its difficulties.

And so the mighty sculptor, painter, and poet reached old age. An infirmity which settled on him in 1544, and the death of Vittoria Colonna in 1547, left him broken in health and heart. But his strength held on for many a year longer yet. His father and brothers were dead, and his family sentiment concentrated itself on a nephew, Leonardo, to whom he showed unremitting practical kindness, coupled with his usual suspiciousness and fitfulness of temper. In almost all his relations the old man continued to the end to manifest the same loyal and righteous heart, accompanied by the same masterful, moody, and estranging temper, as in youth. Among the artists of the younger generation he held a position of absolute ascendancy and authority; nor was his example, as we have said, by any means altogether salutary for them. To artists, and to a certain number of chosen friends, belonging chiefly to the lettered, diplomatic, and secretarial classes, he was more accessible and affable than he had been to any one in earlier days, though still formidable in moods of scorn and scoffing. His great age and fame made him the most honoured citizen of Rome, to whom the highest, both of his fellow countrymen and foreigners, were eager to do homage. During the last years of his life he made but few more essays in sculpture, and those not successful, but was much employed in the fourth art in which he excelled—that of architecture. A succession of popes demanded his services for the embellishment of Rome. Between 1536 and 1546 he was engaged on plans for the rearrangement and reconstruction of the great group of buildings on the Capitol—plans which were only partially and imperfectly carried out during his lifetime and after his death. For Paul III. he finished the palace called after the name of the pope's family the Farnese. On the death of Antonio da San Gallo he succeeded to the onerous and coveted office of chief architect of St Peter's church, for which he remodelled all the designs, living to see some of the main features, including the supports and lower portion of the great central dome, carried out in spite of all obstacles, according to his plans. The dome as it stands is his most conspicuous and one of his noblest monuments: the body of the church was completed in a manner quite different from his devising. Other great architectural tasks on which he was engaged were the reconstruction of the Porta Pia, and the conversion of a portion of the baths of Diocletian into the church of Sta Maria degli Angeli; the great cloister with its hundred columns, now used as the Museo delle Terme, is the only part of this reconstruction which remains as he designed it. At length, in the midst of these vast schemes and responsibilities, the heroic old man's last remains of strength gave way. He died on the threshold of his ninetieth year, on the 18th of February 1564.

Authorities.—For the earlier bibliography of Michelangelo, which is extensive, see the useful though very imperfect compilation of Passerini, *Bibliografia di Michelangelo Buonarroti*, &c. (Florence, 1875). The most important works, taken in chronological order, are the following: P. Giovio, supplement to the fragmentary *Dialogus de viris litteris illustribus*, written soon after 1527, first published by Tiraboschi, *Storia della letteratura italiana* (Modena, 1871); G. Vasari, in *Vite degli più eccellenti architettori, pittori, e scultori*, &c. (Florence, 1550); A. Condivi, *Vita di Michelangelo Buonarroti* (1553); this account, for which the author, a pupil and friend of the master's, had long been collecting materials, was much fuller than that of Vasari, who made use of it in rewriting his own life of Michelangelo for his second edition, which appeared after the master's death (1568). The best edition of Vasari is that by Milanesi (Florence 1878–1883); of Condivi, that by Gori and Mariette (Pisa, 1746); for English readers there is a useful translation with notes, by Sir Charles Holroyd. The first additions of importance were published by Bottari, *Raccolta di lettere sulla pittura*, &c. (Rome, 1754; 2nd ed. by Ticozzi, Milan, 1822); the next by Gaye, *Carteggio inedito* (1840). Portions of the correspondence preserved in the Buonarroti archives were published by Guasti in his notes to the *Rime di Michelangelo Buonarroti* (1863), and by Daelli in *Carte Michelangelsche inedite* (Milan, 1865). Complete biographies of Michelangelo had been meanwhile attempted by J. Harford (London, 1857), and with more power by Hermann Grimm, *Leben Michelangelos* (Hanover, 5th ed., 1879). A great increment of biographical material was at length obtained by the publication, in the four-hundredth year after Michelangelo's birth, of the whole body of his letters preserved in the Buonarroti archives, *Lettere di Michelangelo Buonarroti*, ed. G. Milanesi (Florence, 1875). This material was first employed in a connected but too trivial narrative by A. Gotti, *Vita di Michelangelo* (Florence, 1875). Next followed C. Heath Wilson, *Life and Works of Michelangelo Buonarroti* (Florence, 1876), the technical remarks in which, especially as concerns the fresco paintings, are still valuable. Other lives of Michelangelo are by Anton Springer, in his *Michelangelo u. Raphael* (Leipzig, 1883); J. A. Symonds, *The Life of Michelangelo* (London, 1893), full of valuable matter on the history and spirit of Michelangelo's times, but not trustworthy in the criticism of his works; H. Mackowksy, *Michelagniolo* (Berlin, 1908), excellent in all respects, and in moderate compass; Emile Gebhardt, *Michel-Ange, sculpteur et peintre* (1808) is a handsome volume of reproductions with text. *Michelangelo*, by Fritz Knapp, in the *Klassiker der Kunst* series (Stuttgart, 1906) is a very useful compendium. For the early works of Michelangelo the standard authority is H. Wölfflin, *Die Jugendwerke Michelangelos* (Munich, 1891, and later editions), a masterly work, though at variance with Berlin official opinion. The most elaborate study of the Sixtine frescoes, magnificently illustrated, is by E. Steinmann, *Die Sixtinische Kapelle*, vol. ii. (Munich, 1905). Consult also C. Justi, *Michelangelo* (Leipzig, 1903), and with caution H. Thode, *Michelangelo u. das Ende der Renaissance* (Berlin, 1902–1903). Of the poems of Michelangelo the first sound edition is that already referred to, G. Guasti, *Rime di Michelangelo Buonarroti* (1863); in earlier editions the text had been recklessly tampered with, and the rugged individuality of the master's style smoothed down. An edition with German translations was published by Hasenclever (Leipzig, 1875); and a thorough critical edition by Karl Frey (Berlin, 1897); for the English student the translations by J. A. Symonds, in *Sonnets of Michelangelo and Campanella* (London, 1878) are invaluable. On the drawings of Michelangelo see especially B. Berenson, *The Drawings of Florentine Painters* (London, 1903). A comprehensive work on the same subject, in which the most important examples are reproduced and discussed, unfortunately not arranged chronologically, is Karl Frey, *Die Zeichnungen Michelangelos* (Berlin, 1908 seq.), still in progress. An elaborate life by the same author (Karl Frey, *Michelagniolo Buonarroti, sein Leben und seine Werke*) is also in progress, but is more to be prized for documentary fullness and accuracy than for critical insight.

(S. C.)

MICHELET, JULES (1798–1874), French historian, was born at Paris on the 21st of August 1798, of a family which had Huguenot traditions. His father was a master printer, not very prosperous, and the son at an early age assisted him in the actual work of the press. A place was offered him in the imperial printing office, but his father was able to send him to the famous Collège or Lycée Charlemagne, where he distinguished himself. He passed the university examination in 1821, and was shortly after appointed to a professorship of history in the Collège Rollin. Soon after this, in 1824, he married. The period of the restoration and the July monarchy was one of the most favourable to rising men of letters of a somewhat scholastic cast that has ever been known in France, and Michelet had powerful patrons in Villemain, Victor Cousin and others. But, though he was an ardent politician (having from his childhood embraced republicanism and a peculiar variety of romantic free-thought), he was first of all a man of letters and an inquirer into the history of the past.

His earliest works were school-books, and they were not written at a very early age. Between 1825 and 1827 he produced divers sketches, chronological tables, &c., of modern history. His *Précis* of the subject, published in the last-mentioned year, is a sound and careful book, far better than anything that had appeared before it, and written in a sober yet interesting style. In the same year he was appointed maître de conférences at the École normale. Four years later, in 1831, the *Introduction à l'histoire universelle* showed a very different style, exhibiting no doubt the idiosyncrasy and literary power of the writer to greater advantage, but also displaying the peculiar visionary qualities which made Michelet the most stimulating, but the most untrustworthy (not in facts, which he never consciously falsifies, but in suggestion) of all historians. The events of 1830 had unmuzzled him, and had put him in a better position for study by obtaining for him a place in the Record Office, and a deputy-professorship under Guizot in the literary faculty of the university. Very soon afterwards he began his chief and monumental work, the *Histoire de France*. But he accompanied this with numerous other books, chiefly of erudition, such as the *Œuvres choisies de Vico*, the *Mémoires de Luther écrits par lui-même*, the *Origines du droit français*, and somewhat later the *Procès des templiers*. 1838 was a year of great importance in Michelet's life. He was in the fullness of his powers, his studies had fed his natural aversion to the principles of authority and ecclesiasticism, and at a moment when the revived activity of the Jesuits caused some real and more pretended alarm he was appointed to the chair of history at the Collège de France. Assisted by his friend Edgar Quinet, he began a violent polemic against the unpopular order and the principles which it represented, a polemic which made their lectures, and especially Michelet's, one of the most popular resorts of the day. He published, in 1839, his *Histoire romaine*, but this was in his graver and earlier manner. The results of his lectures appeared in the volumes *Le Prêtre, la femme, et la famille* and *le peuple*. These books do not display the apocalyptic style which, partly borrowed from Lamennais, characterizes Michelet's later works, but they contain in miniature almost the whole of his curious ethico-politico-theological creed—a mixture of sentimentalism, communism, and anti-sacerdotalism, supported by the most eccentric arguments, but urged with a great deal of eloquence. The principles of the outbreak of 1848 were in the air, and Michelet was not the least important of those who condensed and propagated them: indeed his original lectures were of so incendiary a kind that the course had to be interdicted. But when the actual revolution broke out Michelet, unlike many other men of letters, did not attempt to enter on active political life, and merely devoted himself more strenuously to his literary work. Besides continuing the great history, he undertook and carried out, during the years between the downfall of Louis Philippe and the final establishment of Napoleon III., an enthusiastic *Histoire de la révolution française*. Despite or because of its enthusiasm, this was by no means Michelet's best book. The events were too near and too well known, and hardly admitted the picturesque sallies into the blue distance which make the charm and the danger of his larger work. In actual picturesqueness as well as in general veracity of picture, the book cannot approach Carlyle's; while as a mere chronicle of the events it is inferior to half a dozen prosaic histories older and younger than itself.

The *coup d'état* lost Michelet his place in the Record Office, as, though not in any way identified with the republic administratively, he refused to take the oaths to the empire. But the new régime only kindled afresh his republican zeal, and his second marriage (with Mlle Adèle Malairet, a lady of some literary capacity, and of republican belongings) seems to have further stimulated his powers. While the history steadily held its way, a crowd of extraordinary little books accompanied and diversified it. Sometimes they were expanded versions of its episodes, sometimes what may be called commentaries or companion volumes. In some of the best of them natural science, a new subject with Michelet, to which his wife is believed to have introduced him, supplies the text. The first of these (by no means the best) was *Les Femmes de la révolution* (1854), in which Michelet's natural and inimitable faculty of dithyrambic too often gives way to tedious and not very conclusive argument and preaching. In the next, *L'Oiseau* (1856), a new and most successful vein was struck. The subject of natural history was treated, not from the point of view of mere science, nor from that of sentiment, nor of anecdote nor of gossip, but from that of the author's fervent democratic pantheism, and the result, though, as was to be expected, unequal, was often excellent. *L'Insecte*, in the same key, but duller, followed. It was succeeded by *L'Amour* (1859), one of the author's most popular books, and not unworthy of its popularity, but perhaps hardly his best. These remarkable works, half pamphlets half moral treatises, succeeded each other as a rule at the twelve months' interval, and the succession was almost unbroken for five or six years. *L'Amour* was followed by *La Femme* (1860), a book on which a whole critique of French literature and French character might be founded. Then came *La Mer* (1861), a return to the natural history class, which, considering the powers of the writer and the attraction of the subject, is perhaps a little disappointing. The next year (1862) the most striking of all Michelet's minor works, *La Sorcière*, made its appearance. Developed out of an episode of the history, it has all its author's peculiarities in the strongest degree. It is a nightmare and nothing more, but a nightmare of the most extraordinary verisimilitude and poetical power.

This remarkable series, every volume of which was a work at once of imagination and of research, was not even yet finished, but the later volumes exhibit a certain falling off. The ambitious *Bible de l'humanité* (1864), an historical sketch of religions, has but little merit. In *La Montagne* (1868), the last of the natural history series, the tricks of staccato style are pushed even farther than by Victor Hugo in his less inspired moments, though—as is inevitable, in the hands of such a master of language as Michelet—the effect is frequently grandiose if not grand. *Nos fils* (1869), the last of the string of smaller books published during the author's life, is a tractate on education, written with ample knowledge of the facts and with all Michelet's usual sweep and range of view, if with visibly declining powers of expression. But in a book published posthumously, *Le Banquet*, these powers reappear at their fullest. The picture of the industrious and famishing populations of the Riviera is (whether true to fact or not) one of the best things that Michelet has done. To complete the list of his miscellaneous works, two collections of pieces, written and partly published at different times, may be mentioned. These are *Les Soldats de la révolution* and *Légendes démocratiques du nord.*

The publication of this series of books, and the completion of his history, occupied Michelet during both decades of the empire. He lived partly in France, partly in Italy, and was accustomed to spend the winter on the Riviera, chiefly at Hyères. At last, in 1867, the great work of his life was finished. In the usual edition it fills nineteen volumes. The first of these deals with the early history up to the death of Charlemagne, the second with the flourishing time of feudal France, the third with the 13th century, the fourth, fifth, and sixth with the Hundred Years' War, the seventh and eighth with the establishment of the rural power under Charles VII. and Louis XI. The 16th and 17th centuries have four volumes apiece, much of which is very distantly connected with French history proper, especially in the two volumes entitled *Renaissance* and *Réforme.* The last three volumes carry on the history of the 18th century to the outbreak of the Revolution. Michelet was perhaps the first historian to devote himself to anything like a picturesque history of the middle ages, and his account is still the most vivid that exists. His inquiry into manuscript and printed authorities was most laborious, but his lively imagination, and his strong religious and political prejudices, made him regard all things from a singularly personal point of view. Circumstances which strike his fancy, or furnish convenient texts for his polemic, are handled at inordinate length, while others are rapidly dismissed or passed over altogether.

Uncompromisingly hostile as Michelet was to the empire, its downfall and the accompanying disasters of the country once more stimulated him to activity. Not only did he write letters and pamphlets during the struggle, but when it was over he set himself to complete the vast task which his two great histories had almost covered by a *Histoire du XIXe siècle.* He did not, however, live to carry it farther than Waterloo, and the best criticism of it is perhaps contained in the opening words of the introduction to the last volume—"l'âge me presse." The new republic was not altogether a restoration for Michelet, and his professorship at the Collège de France, of which he contended that he had never been properly deprived, was not given back to him. He died at Hyères on the 9th of February 1874.

Almost all Michelet's works, the exceptions being his translations, compilations, &c., are published in uniform size and in about fifty volumes, partly by Marpon and Flammarion, partly by Calmann Lévy. He has not received much recent attention from critics and monographers, but his *Origines du droit français, cherchées dans les symboles et formules du droit universel* was edited by Émile Faguet in 1890 and went into a second edition in 1900. See G. Monod, *Jules Michelet; Études sur la vie et ses œuvres* (Paris, 1905).

(G. Sa.)

MICHELET, KARL LUDWIG (1801–1893), German philosopher, was born on the 4th of December 1801, at Berlin, where he died on the 16th of December 1893. He studied at the gymnasium and at the university of his native town, took his degree as doctor of philosophy in 1824, and became professor in 1829, a post which he retained till his death. Educated in the doctrine of Hegel, he remained faithful to his early teaching and spent his life in defending and continuing the Hegelian tradition. His first notable work was the *System der philosophischen Moral* (Berlin, 1828), an examination of the ethical theory of responsibility. In 1836 he published, in Paris, a treatise on the *Metaphysics* of Aristotle, written in French and crowned by the Académie des Sciences Morales et Politiques. He wrote also two other treatises on Aristotle. *Nikomachische Ethik* (2nd ed., 1848) and *Die Ethik des Aristoteles in ihrem Verhältniss zum System der Moral* (1827). His own views are best expressed in his *Vorlesungen über die Persönlichkeit Gottes* (1841) and *Die Epiphanie der ewigen Persönlichkeit des Gottes.* The philosophical theology developed in these works has been described as a "Neo-Christian Spiritualism."

Among his other publications may be mentioned *Geschichte der letzten Systeme der Philos. in Deutschland von Kant bis Hegel* (1837–1838); *Anthropologie und Psychologie* (1840); *Esquisse de logique* (Paris, 1856); *Naturrecht oder Rechtsphilosophie* (1866); *Hegel der unwiderlegte Weltphilosoph* (1870), *Wahrheit aus meinem Leben* (1886). From 1832 to 1842, Michelet was engaged in publishing the complete works of Hegel, and in 1845 he founded the Berlin Philosophical Society, which has continuously represented the Hegelianism of Germany. He was the first editor of *Der Gedanke* (1860), the official organ of the society.

MICHELL, JOHN (1724–1793), English natural philosopher and geologist, was born in 1724, and educated at Queens' College, Cambridge. His name appears fourth in the Tripos list for 1748–1749; and in 1755 he was moderator in that examination. He became M.A. in 1752, and B.D. in 1761. He was a fellow of his college, and was appointed Woodwardian professor of geology in 1762, and in 1767 rector of Thornhill in Yorkshire, where he died on the 29th of April 1793. He was elected a fellow of the Royal Society in the same year as Henry Cavendish (1760). In 1750 he published at Cambridge a work of some eighty pages entitled *A Treatise of Artificial Magnets, in which is shown an easy and expeditious method of making them superior to the best natural ones.* Besides the description of the method of magnetization which still bears his name, this work contains a variety of accurate magnetic observations, and is distinguished by a lucid exposition of the nature of magnetic induction. He was the original inventor of the torsion balance, which afterwards became so famous in the hands of its second inventor Coulomb. Michell described it in his proposal of a method for obtaining the mean density of the earth. He did not live to put his method into practice; but this was done by Henry Cavendish, who made, by means of Michell's apparatus, the celebrated determination that now goes by the name of Cavendish's experiment (*Phil. Trans.*, 1708). His most important geological essay was that entitled *Conjectures concerning the Cause and Observations upon the Phaenomena of Earthquakes* (*Phil. Trans.*, li. 1760), which showed a remarkable knowledge of the strata in various parts of England and abroad.

Michell's other contributions to science are: "Observations on the Comet of January 1760 at Cambridge, *Phil. Trans.* (1760); "A Recommendation of Hadley's Quadrant for Surveying," ibid. (1765); "Proposal of a Method for measuring Degrees of Longitude upon Parallels of the Equator," ibid. (1766); "An Inquiry into the Probable Parallax and Magnitude of the Fixed Stars," ibid. (1767); "On the Twinkling of the Fixed Stars," ibid. (1767); "On the Means of Discovering the Distance, Magnitude, &c., of the Fixed Stars," ibid. (1784).

MICHEL OF NORTHGATE, DAN (*fl.* 1340), English writer, the author of the *Ayenbite of Inwyt.* Nothing is known of him except what can be gathered from his work. It is a literal translation in the Kentish dialect of a French treatise entitled *Le Somme des vices et des vertues* (also known as *Le Miroir du monde* or *Le Livre des commandemens*, &c.), which was written in 1279 by Laurentius Gallus, a Dominican monk and confessor to Philip III. of France. This work was translated into Flemish, Catalonian, Spanish and Italian, and appears in no less than six English translations. Dan Michel's autograph MS. is preserved in Arundel MS. 57, which states that the work was completed in the year 1340 on the eve of the apostles Simon and Jude by Dan Michel of Northgate, a brother of the cloister of St Austin of Canterbury. The value of the book is chiefly philological as an authenticated and dated example of the southern dialect.

The *Ayenbite of Inwyt* was edited for the Roxburghe Club by the Rev Joseph Stevenson in 1855, and for the Early English Text Soc. by Richard Morris in 1876.

MICHELOZZO DI BARTOLOMMEO (1391–1472?), Italian sculptor, was a Florentine by birth, the son of a tailor, and in early life a pupil of Donatello. He worked in marble, bronze and silver. The statue of the young St John over the door of the Duomo at Florence, opposite the Baptistery, is by him; and he also made the beautiful silver statuette of the Baptist on the altar-frontal of San Giovanni. Michelozzo's great friend and patron was Cosimo dei Medici, whom he accompanied to Venice in 1433 during his short exile. While at Venice, Michelozzo built the library of San Giorgio Maggiore, and designed other buildings there. In 1428, together with Donatello, he erected an open-air pulpit at an angle of the cathedral of St Stephen at Prato. The magnificent Palazzo dei Medici at Florence built by Cosimo, was designed by him; it is one of the noblest specimens of Italian 15th-century architecture, in which the great taste and skill of the architect has combined the delicate lightness of the earlier Italian Gothic with the massive stateliness of the classical style. With great engineering skill Michelozzo shored up, and partly rebuilt, the Palazzo Vecchio, then in a ruinous condition, and added to it many important rooms and staircases. When, in 1437, through Cosimo's liberality, the monastery of San Marco at Florence was handed over to the Dominicans of Fiesole, Michelozzo was employed to rebuild the domestic part and remodel the church. For Cosimo I. he designed numerous other buildings, mostly of great beauty and importance. Among these were a guest-house at Jerusalem for the use of Florentine pilgrims, Cosimo's summer villa at Careggi, and the strongly fortified palace of Cafagiuolo in Mugello. For Giovanni dei Medici, Cosimo's son, he built a very large and magnificent palace at Fiesole. In spite of Vasari's statement that he died at the age of sixty-eight, he appears to have lived till 1472. He is buried in the monastery of San Marco, Florence. Though skilled both as a sculptor and engineer, his fame chiefly rests on his architectural works, which claim for him a position of very high honour even among the greatest names of the great 15th-century Florentines.

See Hans Stegmann, *Michelozzo di Bartolommeo, eine kunstgeschichtliche Studie* (1888); Fritz Wolff, *Michelozzo di Bartolommeo* (1900); cf. also Hans Semper, *Donatello* (1887).

MICHIGAN, a north central state of the United States, situated between latitudes 41° 44′ and 47° 30′ N.[1] and longitudes 82° 25′ and 90° 31′ W., and consisting of two peninsulas—the upper or northern and the lower or southern—separated by a strait. The upper or northern peninsula is bounded N. by Lake Superior; E. by lakes Superior, George, Huron, and Michigan, and by St Mary's River, which separates it from the Province of Ontario, Canada; S. by lakes Huron and Michigan and the Straits of Mackinac, which separate it from the lower peninsula; and S. and W. by Wisconsin, and the Menominee, Montreal and Brulê Rivers, which separate it in part from Wisconsin. The lower or southern peninsula is bounded N. by lakes Michigan and Huron and the Straits of Mackinac, E. by lakes Huron, St Clair and Erie, and the St Clair and Detroit Rivers, which separate it from Ontario; S. by Ohio and Indiana, and W. by Lake Michigan. In size Michigan ranks eighteenth among the states of the Union, its total area being 57,980 sq. m., of which 500 sq. m. are water surface.[2]

Physical Features.—Physiographically the history of the state is similar to that of Minnesota. The northern part is rugged mountainous "old land," not completely worn down by erosion; and the southern part is a portion of the old coastal plain, whose layers contain salt, gypsum and some inferior coal. Lake Huron on the east and Lake Michigan on the west of the lower peninsula are each 581⅓ ft. above sea-level, and Lake Superior on the north of the upper peninsula is 602 ft. above sea-level. For the most part the surface of the state is gently undulating and at a slight elevation above the lakes, but low marsh lands are common to many sections; the north part of the lower peninsula is occupied by a plateau of considerable dimensions, and the north-west part of the upper peninsula is rugged with hills and mountains. Crossing the lower peninsula from Saginaw Bay west by south through the valleys of the Saginaw, Maple and Grand rivers, is a depression—the former channel of an old glacial river—in which elevations for a considerable area are less than 100 ft. above the lakes. To the south-east of this depression a water-parting with summits varying from about 400 to 600 ft. above the lakes extends from a point between Saginaw Bay and Lake Huron south by west to the south border of the state and beyond. The east slope descends quite rapidly to a low flat belt from 5 to 40 m. wide along the east border of the state south from Lake Huron. From Lake Huron to the south-east shore of Saginaw Bay a wide sandy beach is followed northward by precipitous shores abounding in rocks and bluffs. West of the divide and south of the depression, south-west Michigan is occupied by the valleys of the St Joseph, Kalamazoo and Grand rivers, by the gently rolling uplands that form the parting divides between them, and by sand dunes, which here and there rise to a height of from 100 to 200 ft. or more along the shore of Lake Michigan, and are formed on this side (but not on the Wisconsin side) of the lake by the prevailing west winds. The north and north-west portions of the lower peninsula—including the counties of Roscommon and Missaukee, parts of Wexford and Ogemaw, and those to the north and north-west of these—are occupied by a rolling plateau which attains an elevation at its highest point, north of its centre, of upwards of 1100 ft. above Lake Michigan; to the south of this plateau the land slopes gently down to the depression and to the low shores of Lake Michigan and Saginaw Bay. The surface of the upper peninsula is more irregular than that of the lower peninsula. A portion extending through the middle from east to west and south, from west of the centre to Green Bay, is either flat and even swampy or only gently undulating. Eastward from Green Bay are two ranges of hills: the one lining the south shore and ranging from 100 to 300 ft. in height, the other close to or touching the north shore and reaching in places an elevation of 600 ft. above Lake Superior. The famous Pictured Rocks in Alger county on the lake shore, east of Munising, form the west portion of this north range; they are of sandstone formation, extend for several miles along the coast, rise almost perpendicularly from the water's edge, and display an interesting diversity of shapes as well as a great variety of tints and hues, especially of gray, blue, green and yellow. The most rugged portion of the state is farther west. South and south-east of Keweenaw Bay, in the Marquette iron district, is an irregular area of mountains, hills, swamps and lakes, some of the mountain peaks of the Huron Mountains (in Marquette county) rising to an elevation of 1400 ft. or more above the lake. These and a peak in the Porcupine Mountains (2023 ft. above the sea) in the north-west part of Ontonagon county are the highest in the state. To the south of this is the Menominee iron district, marked somewhat regularly by east and west ridges. Extending in a general north-east and south-west direction through Keweenaw peninsula to the Wisconsin border and beyond is the middle of three approximately parallel ranges, separated from each other by flat lands, with here and there an isolated peak (in the Porcupine Mountains) having an elevation of from 900 to 1400 ft. above the lake. The north portion of these ranges, together with Isle Royale some distance farther north, which is itself traversed by several less elevated parallel ridges, contains the Michigan copper-bearing rocks; while to the south, along the Wisconsin border, is another iron district, the Gogebic. The rivers of the entire state consist of numerous small streams of clear water. In the interior of the upper peninsula, along the east border of the lower peninsula south from Lake Huron, and in Saginaw valley, they are rather sluggish; but many of the larger streams of the lower peninsula have sufficient fall to furnish a large amount of water-power, while the small streams that flow into Lake Superior from the central portion of the upper peninsula as well as some of the larger ones farther west, have several falls and rapids; in places also they are lined with steep, high banks. Most of the larger rivers of the state—the Muskegon, Grand, St Joseph, Manistee and Kalamazoo—are in the west portion of the lower peninsula. Several thousand lakes of clear water, formed by glacial action, dot the surface of the state, and many of them are lined with picturesque woodland shores. Islands in lakes Superior, Michigan and Huron are scarcely less numerous.

---

[1] This is the northernmost point of the mainland; the most northerly of the islands north-east of Isle Royal and belonging to Michigan is more than 40′ further north.

[2] In addition, within the boundaries of Michigan, are approximately 16,653 sq. m. of Lake Superior, 12,992 sq. m. of Lake Michigan, 9925 sq. m. of Lake Huron and 460 sq. m. of lakes St Clair and Erie.

Fauna and Flora.—Michigan, especially the north portion, still abounds in game. The mammals include black bear, deer, lynx, porcupine, fox, squirrels, hares, rabbits, musk rats, minks, weasels, skunks and woodchucks. Among the game birds are quails ("Bob White"), "partridges" (ruffed grouse), ducks, geese, woodcocks, snipes and plovers. Of song birds the favourites are the robin, thrushes, bobolink, oriole, chickadee, meadow-lark, cat-bird, bluebird, wrens and warblers. Among fishes, white fish, lake trout, perch, herring, sun-fish, bass, sturgeon, pickerel, suckers, German carp and fresh-water drum abound in the lakes. The speckled trout thrives in many of the streams.

Before it was settled by the whites the area now included in Michigan was a forest, except in the south-west, where there were a few small prairies, possibly cleared by the Indians. The remainder of the south part of this area for about 60 m. along the southern boundary was a part of the great hardwood forest of the Ohio Basin with woods varying with soil and drainage: on the drier gravel lands were oak forests consisting of red, black and white oak, hickory, ash, cherry, basswood and walnut; in depressions there were maple, elm, ash, beech, sycamore, poplar and willow; and in the south-east there were a few chestnuts and tulip trees. North of this southern hardwood forest there were pine forests on the sandier land, mixed hardwoods and conifers on the loam and clay, and tamaracks and cedar in the swamps. The sandy lands were in part burnt over by Indians, and there was a growth of scrub oak, aspens and huckleberry bushes. The tamarack and cedar swamps now have a growth, especially on their edges, of spruce, balsam, white pine, soft maple, ash and aspens. In 1909 about 25 % of the area was "cut over" or "burned over" lands, mostly the old pine woods, the region of the old hardwood forest was almost entirely farmland, and about 40 % of the state was still in woods. Red oak, birch, elm, ash, white cedar, hemlock, basswood, spruce, poplar, balsam, fir and several other kinds of trees are found in many sections; but a large portion of the merchantable timber, especially in the lower peninsula, has been cut.[1] Among forest shrubs are the willow, hazel, alder, shrub maple, birch, hawthorn, dogwood, elderberry, viburnum and snowberry. Yews are common in the north, and dwarf juniper in the south. In 1900 the woodland area, including stump lands, was estimated at 38,000 sq. m., or nearly two-thirds of the entire state. Huckleberry, blackberry and raspberry bushes are common in the north sections. Smilax, clematis, honeysuckle and woodbine are the commoner forest vines.

Soil.—The soil of south-west and south-east Michigan is for the most part a dark clay loam or muck; in the north central part of the lower peninsula it is a light sandy loam, along the Huron shore it is heavy with blue clay, in the mining districts of the north-west the rocks are usually either barren or very thinly covered; and elsewhere in the state the soil is generally rich in a variety of mineral elements, and varies chiefly in the proportions of vegetable loam, sand or gravel, and clay.

Climate.—Although the temperature of the entire lower peninsula is considerably influenced by the lakes, yet, the prevailing winds being westerly, it is in the west portion of that peninsula that the moderation is greatest, both the summer and winter isotherms being there deflected more than half the length of the peninsula. On the other hand, the prevailing winds of the upper peninsula being north-westerly, the lakes have little effect on the temperature there; and so, while in the south-west the extremes are not great, in the rest of the state they have ranged within two years from 104° F. at points in the south-east to 49° F. in the north-west. Throughout the state July is invariably the warmest month, February the coldest, the mean annual temperature is about 45° F. The mean annual precipitation is not far from 31 in., a little more than one-half of which falls during the five growing months from May to October; the rain is evenly distributed over all parts of the state, but the snow is exceptionally heavy along the north shore of the upper peninsula.

Productions.—Of the total land surface of the state in 1900 48·08 % (in 1904, 47·1 %) was included in farms and 67·2 % (in 1904, 66·9 %) of the farm land was improved; the total number of farms was 203,261 (in 1904, 189,167), of which 143,688 contained less than 100 acres, 54,556 others contained less than 260 acres, and 136 contained 1000 acres or more, the average size being 86·4 acres (in 1904, 91·5 acres). Of the total number of farms 168,814 were operated by the owners (in 1904, 161,037 by owners and 914 by managers), 22,482 (in 1904, 19,525) by share tenants, 9731 (in 1904, 7685) by cash tenants; and 312,462 of the inhabitants of the state, or 34·5 % of all who were engaged in gainful occupations, were farmers. Of the total acreage in 1900 of all crops 58·3 % was in cereals and 28·8 % in hay and forage; of the acreage of cereals 40·8 % was in wheat, 31·8 % in Indian corn, 21·6 % in oats and 3·7 % in rye. In 1907 the buckwheat crop was 852,000 bushels; rye, 5,452,000 bushels; the hay crop, 3,246,000 tons; oats, 30,534,000 bushels; barley, 1,496,000 bushels; wheat 12,731,000 bushels; and Indian corn 57,190,000 bushels. Of livestock, sheep are the most numerous (2,130,000 in 1907), and Michigan's wool clip in 1907 was 14,080,500 lb. The number of neat cattle in 1907 was 1,852,000 (849,000 dairy cows). The number of hogs was 1,388,000; and of horses 704,000.

Michigan produces the bulk of the peppermint crop of the United States, and it is in the front rank as a fruit-producing state.

Barley and buckwheat are grown chiefly in the east part of the lower peninsula south of Saginaw Bay. Potatoes are grown in considerable quantities in the north-west part of the lower peninsula in the vicinity of Grand Traverse Bay as well as throughout the southern portion of the state; the largest crops of beans are grown in the south central part of the lower peninsula, and of peas in the counties bordering on Lake Huron. Kalamazoo, Jackson, Washtenaw, Lenawee, Ingham, Bay and Muskegon are the leading celery-producing counties; the peppermint district is in the south-west corner of the state; and market gardening is an important industry both in the south-west and in the south-east counties. All the principal fruits are grown in largest quantities in what is commonly known as the fruit belt in the south-west, particularly in Berrien, the corner county.

The fresh-water fish caught in the Great Lakes by residents in Michigan exceed in value those caught by residents of other states, and in 1907 the catch was valued at $1,806,767. Nearly one-half both in quantity and value are taken from Lake Michigan, and, although as many as twenty kinds are caught in considerable quantities, more than 90 % of the value of the catch consists of trout, herring, white fish and perch. Both the state government and the national government have established hatcheries within the state, and state laws protect the industry by regulating the size of mesh in the nets used, prescribing the size of fish that may be taken and kept, establishing close seasons for several kinds of fish, and by other limitations.

Minerals.—Of the mineral products (for which the state is noted) iron is the most valuable. This mineral was discovered in the Marquette district along the shore of Lake Superior early in the 18th century, but active operations for mining it did not begin until 1845; in 1877 mining of the same mineral began farther south in the Menominee district, and seven years later farther west along the Wisconsin border in Gogebic county. The annual product steadily increased from 3000 long tons in 1854 to 11,830,342 in 1907; from 1890 to 1901 Michigan ranked first in the union as an iron-producing state, but after 1901 its product was exceeded by that of Minnesota. Up to 1909 it was estimated that 380,417,085 tons of ore were shipped from the Lake Superior region. Next in value among the mineral products is copper; there are about twenty copper mines in Keweenaw peninsula and its vicinity. The Calumet and Hecla mine, in the central part of that peninsula, is probably the most profitable copper mine in the world; up to 1909 it had paid

---

[1] Under the revised constitution of 1908 the legislature is authorized to provide for the reforestation of state lands.

about $107,850,000 in dividends. Copper mining in the state began about the same time as iron mining, and the quantity mined increased from 12 long tons in 1845 to 102,543 in 1906 (in 1907, 97,175 long tons). From 1847 to 1887 the product of Michigan exceeded that of any other state; from 1847 to 1883 its copper product was more than one-half that of all the states, but after 1887 (except in 1891) more of that mineral was mined in Montana than in Michigan, and in 1906 and in 1907 the yield in both Arizona and Montana was greater than in Michigan. Fields of bituminous coal extend over an area of over 10,000 sq. m. in the central portion of the lower peninsula; but its quality is inferior. The mining of coal began in Jackson county in 1835 and there was a slow increase in the output until 1882 (135,339 short tons); then there was a tendency to decrease until 1897, from which time the product increased from 223,592 short tons to 2,035,858 short tons in 1907. The principal mines are in Saginaw, Bay, Eaton, Jackson, Huron and Shiawassee counties. Salt wells are numerous in the middle and south-east sections of the lower peninsula; the first successful one was drilled in Saginaw county in 1859 and 1860. For a number of years prior to 1893 Michigan was the leading salt-producing state, and, though her output was subsequently (except in 1901) exceeded by that of New York, it continued to increase up to 1905, when it was 9,492,173 barrels; in 1907, the product was 10,786,630 barrels. Gypsum is obtained from deposits along the banks of the Grand river in Kent county and in the vicinity of Alabaster along the shore of Lake Huron in Iosco county. Operations on the deposit near Grand Rapids were begun in 1841, and although that near Alabaster was opened in 1862, it was not until 1902 that it became of much importance; in that year the output of the state was 208,563 short tons; in 1907 317,261 short tons were mined. Marl is found in the south part of the state; limestone most largely in the north part of the lower peninsula, and the east part of the upper peninsula; and the production of Portland cement increased rapidly from 77,000 barrels in 1898 to 3,572,668 in 1907. Besides limestones and dolomites, the only building stone of much commercial importance is the Potsdam sandstone, extensive beds of which lie in the north part of the upper peninsula. Grindstones are produced in considerable quantity in Huron county. A small quantity of petroleum is obtained from thirteen wells in St Clair county in the east part of the lower peninsula; and the mineral waters at Mount Clemens, Benton Harbor and Alma are of considerable commercial value for medicinal purposes.

Manufactures.—In 1900 the value of the manufactured products of Michigan amounted to $356,944,082, which was an increase of 28·4% over that of 1890, and by 1904 there was a further increase of 20·19%.[1] During the same period, however, the value of the products of the lumber and timber industry, which in 1870, 1880 and 1890 was greater than that of any other state, and in 1900 was still more than twice as great as that of the products of any other manufacturing industry in the state and was exceeded only by that of the product of Wisconsin, decreased from $83,121,969 in 1890 to $53,915,647 (35·1%) in 1900, and to $40,569,335 in 1904, this decrease being due to the fact that the large quantities of raw material (both hard wood and pine) formerly found in the forests of Michigan had become so far exhausted that much of it had to be brought in from other states and from Canada. The value of the products of the furniture factories and of the planing mills, nevertheless, has steadily increased; that of the furniture factories (of which Grand Rapids is the leading centre not only in Michigan but in the United States) rising from $10,767,038 in 1890 to $14,614,506 in 1900 and $18,421,735 in 1904, and that of the planing mills from $10,007,603 in 1890 to $12,469,532 in 1900 and $14,375,467 in 1904. The total value of the lumber and timber products, the furniture products, and the planing-mill products amounted in 1900 to $80,999,685; the value of those manufactures based upon minerals mined or quarried amounted in the same year to $83,730,930.

Another important class of manufactures is that based on agriculture: the value of flour and grist mill products amounted to $21,643,547 in 1900, and $26,512,027 in 1904; that of food preparations, for which Battle Creek is noted, to $1,891,516 in 1900 and $6,753,699 in 1904; that of agricultural implements to $6,339,508 in 1900 and $8,719,719 in 1904; and of malt liquors to $5,296,825 in 1900 and $6,999,251 in 1904.

Among other manufactures in which the state ranks high and in which there was a large increase in value during the same period are: leather, carriages and waggons, chemicals, paper and wood pulp and beet sugar. In 1904 Michigan manufactured automobiles valued at $6,876,708.

The ten leading manufacturing centres are, in the order of the value of their products in 1904: Detroit, Grand Rapids, Kalamazoo, Battle Creek, Saginaw, Jackson, Lansing, Muskegon, Bay City and Port Huron, all in the south half of the lower peninsula.

Communications.—The building of railways in Michigan began in 1830, but little progress had been made in 1837 when the state began the construction of three railways and two canals across the south half of the lower peninsula. The Michigan Central was completed from Detroit to Ypsilanti in January 1838, a portion of the Michigan Southern was in operation in November 1840, and considerable work was done on the proposed Michigan Northern and the two canals. By 1846, however, the state had proved itself incompetent to carry on the work and sold its interests to private companies. In 1850 there were 342 m. completed, and from then until 1880 the mileage increased to 3938; but the great period of railway building in Michigan was in the decade from 1880 to 1890, when the mileage was increased to 7108·48. By the close of 1908 it had further increased to 8629·35. The principal lines are the Michigan Central, the Père Marquette, the Lake Shore & Michigan Southern, the Grand Rapids & Indiana, the Ann Arbor, the Grand Trunk, the Chicago & North-Western, the Duluth South Shore & Atlantic, the Minneapolis, St Paul & Sault Ste. Marie, and the Chicago, Milwaukee & St Paul. A board of railway commissioners, which in 1907 succeeded a commissioner (whose office was created in 1873) hears complaints, has power to issue various orders and permits of minor importance to railway companies, and reports annually to the governor.[2] The legislature is empowered to appoint a commission to fix transportation rates for railways and express companies. Besides railway communication Michigan has a coast line of about 1600 m., along which vessels of 2000 tons can sail and find several good harbours, the water communication having been extended and improved by several canals, among which are the Sault Ste. Marie, which passes the rapids of St Mary's River; the St Clair Flats, at the north end of Lake St Clair, by which a deeper channel is made through shallow water; and the Portage Lake, in the copper district, which connects that lake with Lake Superior. The state undertook to construct that at Sault Ste. Marie in 1837 but little had been accomplished in 1852 when the national government granted 750,000 acres of land to the state in aid of the enterprise, and three years after that the canal was completed. Since its completion, the national government has enlarged its locks so as to make it navigable for vessels drawing 21 ft. of water. The national government constructed the canal at the St Clair Flats in 1871 and contributed land for aid in the construction of that connecting lakes Portage and Superior, which was completed in 1873 and passed under national control in 1891.

Population.—The population of Michigan in 1880 was 1,636,937; in 1890 it was 2,093,889, an increase of 27·9% within the decade; in 1900 it was 2,420,982, a further increase of 15·6% and in 1910, according to the preliminary returns of the U.S. census, it was 2,810,173. Of the total population in 1900, 2,398,563 or 99·07% were whites, 15,861 were negroes, 6354 were Indians, 240 were Chinese, and 9 were Japanese. 1,879,329 or 77·6% were native born and 541,653 were foreign-born, 184,398 of the foreign-born being natives of Canada (151,915 English; 32,483 French), 125,074 of Germany, 43,839 of England, and 30,406 of Holland. In 1906 982,479 communicants of different denominations were reported: of these 492,135 were Roman Catholics, 128,675 Methodists, 105,803 Lutherans, 50,136 Baptists, 37,900 Presbyterians, 28,345 members of Reformed bodies, and 26,349 members of the Protestant Episcopal Church. In 1900 39·3% of the total population lived in places having at least 2500 inhabitants.

Administration.—The constitution under which Michigan is now governed was first adopted in 1850, when it was felt that the powers which the first one, that of 1835, conferred upon the executive and the legislature were too unrestricted. In 1908 it was revised, and many changes were made.

The constitution admits of amendment by an affirmative vote of two-thirds of the members of each house of the legislature, followed at the next succeeding spring or autumn election by an affirmative vote of a majority of the electors voting upon the question; or an amendment may be proposed by an initiative petition signed by more than 20% of the total number of electors who voted for secretary of state at the preceding election, and such an amendment (unless disapproved by a majority vote in a joint meeting of the two houses of the legislature) is submitted to popular vote at the next election and comes into effect only if it receives a favourable majority of the popular vote. Amendments suggested by the legislature have been frequently adopted, and one, adopted in 1862, provided that the question of a general revision of the constitution shall be submitted to a popular vote once every sixteen years and at such other times as may be provided by law. When this question was so submitted for the first time, in 1866, the vote was to revise; but the revision prepared by a convention called for the purpose was rejected at the polls. The revision by the Constitutional Convention of 1907-1908 was adopted by popular vote in 1908.

---

[1] The 1904 census, taken by the Federal Bureau of the Census in co-operation with the secretary of state of Michigan, covered the year ending on the 30th of June 1904, and is thus not strictly comparable with the "1905" census of manufactures for other states, which were for the year ending on the 31st of December 1904. But like the special census of manufactures in other states, it is confined to establishments under the factory system, and hence its figures are considerably less than they would have been had it been taken on the same basis as that of the 1900 census, which included hand trades and other custom work; for example, on the basis of the 1904 census the value of the manufactured products in 1900 was only $319,691,856, and as that of 1904 was $429,120,060, the real increase was 34·2% instead of 20·19%. In the above text from this point the statistics given for 1900 are for factory products only.

[2] In 1909 telegraph and telephone companies were put under the supervision of the same board.

In its present form the constitution confers suffrage upon every male citizen of the United States who is twenty-one years of age or over and has resided in the state six months and in his township or ward twenty days immediately preceding an election; and any woman may vote in an election involving the direct expenditure of public money or the issue of bonds if she have the qualifications of male electors and if she have property assessed for taxes in any part of the district or territory affected by the election in question. At the head of the executive department is the governor, who is elected for two years, and who at the time of his election must be at least thirty years of age and must have been for five years a citizen of the United States, and for the two years immediately preceding a resident of the state. A lieutenant-governor, for whom the same qualifications are prescribed, is elected at the same time for the same term. Under the first constitution the secretary of state, treasurer, auditor-general, attorney-general, commissioner of the land office, superintendent of public instruction and the judges were all appointed by the governor, but under the present one they are elected and only minor officers are appointed. In 1893 the legislature created a board of four members to be appointed by the governor, one of whom must be a physician, another an attorney, and made it its duty to investigate the case of every convict for whom a petition for pardon is received and then report and recommend to the governor what it deem expedient. The governor's salary is fixed by the revised constitution of 1908 at $5000 a year. The lieutenant-governor succeeds the governor in case of vacancy, and next in order of succession comes the secretary of state.

The legislature, consisting of a Senate of 32 members, and a House of Representatives of 100 members (according to the constitution not less than 64 and not more than 100), meets biennially, in odd-numbered years, at Lansing. Both senators and representatives are elected for a term of two years by single districts, except that a township or city which is entitled by its population to more than one representative elects its representatives on a general ticket. Beginning in 1913 and at each subsequent tenth year, the legislature, under the revised constitution of 1908, rearranges the senatorial districts and reapportions the representatives among the counties and districts, using as a basis the returns of the next preceding decennial census; the taking of a state census between the decennial periods is discontinued.

No bill can pass either house except by an affirmative vote of a majority of the members elected to that house, and on its third reading the ayes and noes must be taken and recorded; for appropriation bills a two-thirds majority of all members elected to each house is required. All legislation must be by bill, legislation by joint and concurrent resolutions thus being prevented. No bill may be passed at a regular session until it has been printed and in possession of each house for five days; no bill may be passed at a special session on any subject not expressly stated in the governor's proclamation or submitted by special message. The governor has ten days (Sundays not being counted) in which to exercise his veto power (which may be applied to any item or items of any bill making appropriations of money and embracing distinct items), and an affirmative vote in each house of two-thirds of the members elected is required to pass a bill over his veto. Under the revised constitution of 1908 any bill passed by the legislature and approved by the governor, except appropriation bills, may be referred by the legislature to the qualified electors; and no bill so referred shall become law unless approved by a majority of the electors voting thereon; no local or special act, passed by the legislature, takes effect until it is approved by a majority vote of the electors in the affected district.

The administration of justice is entrusted to a supreme court, a continually increasing number of circuit courts (thirty-eight in 1909), one probate court in each county, and not exceeding four justices of the peace in each township. The supreme court is composed of one chief justice and seven associate justices, all elected for a term of ten years, not more than two retiring every two years; it holds four sessions annually, exercises a general control over the inferior courts, may issue, hear and determine any of the more important writs, and has appellate jurisdiction only in all other important cases. There is only one circuit court judge for a circuit, unless the legislature provides for the election of more; the term of office is six years. Circuit court judges have original jurisdiction in most matters civil and criminal, hear appeals from the lower courts, and must hold at least four sessions annually in each county of the circuit. Each county elects a judge of probate for a term of four years; he has original concurrent jurisdiction with the circuit court in matters of probate, and has original jurisdiction in all cases of juvenile delinquents and dependents. The legislature may provide for the election of more than one judge of probate in a county with more than 100,000 inhabitants. Justices of the peace are elected by the townships for a term of four years—there are not more than four in each township; in civil matters they have exclusive jurisdiction of cases in which the demand does not exceed $100 and concurrent jurisdiction with the circuit courts in contract cases in which the demand does not exceed $300.

For purposes of local government the state is divided into eighty-three counties, each of which is in turn divided regularly by N. and S. and E. and W. lines into several townships. In the more sparsely inhabited counties of the upper peninsula and in the N.E. section of the lower peninsula the townships are much larger than in other parts of the state. The officers of the township are a supervisor, clerk, treasurer, highway-commissioner, one overseer of highways for each highway district, a justice of the peace, and not more than four constables, all of whom are elected at the annual township meeting in April. The supervisor, two of the justices of the peace and the clerk constitute the township board, whose duty it is to settle claims against the township, audit accounts, and publish annually an itemized statement of receipts and disbursements. The supervisor is also the township assessor, and the several township supervisors constitute the county board of supervisors who equalize property valuations as between townships, authorize townships to borrow money with which to build or repair bridges, are entrusted with the care and management of the property and business of the county, and may borrow or raise by tax what is necessary to meet the more common expenses of the county. Other county officers are a treasurer, clerk, sheriff, register of deeds, attorney, surveyor and two coroners, each elected for a term of two years, a school commissioner elected for a term of four years, and one or more notaries public appointed by the governor.

Under the revised constitution of 1908 the former classification of cities into four classes and the practice of granting special charters were abolished, and the legislature is required to provide by general laws for the incorporation of cities and villages; "such general laws shall limit their rate of taxation for municipal purposes and restrict their powers of borrowing money and contracting debts." Cities and villages are permitted —upon authorization by the affirmative vote of three-fifths of the electors voting on the question—to own and operate, even outside their corporate limits, public utilities for supplying water, light, heat, power and transportation, and may sell and deliver, outside their corporate limits, water, heat, power and light to an amount not more than one-fourth that furnished by them in each case within their corporate limits; but no city or village of less than 25,000 inhabitants may own or operate transportation facilities. Under the revision of 1908 corporate franchises cannot be granted for a longer term than thirty years.

Law.—A wife in Michigan has the same right to her property acquired either before or after marriage as she would have if single, except that she cannot under ordinary circumstances give, grant or sell it to another without her husband's consent. Grounds for a divorce are adultery, physical incapacity at the time of marriage, sentence to imprisonment for three years or more, desertion for two years, habitual drunkenness, extreme cruelty, or, in case of the wife, refusal of the husband to provide for her maintenance when sufficiently able to do so; but in case the parties were married outside of Michigan the party seeking the divorce must reside within the state at least one year before petitioning for the same. An insolvent debtor's homestead—consisting of not more than 40 acres of land with a house thereon, or a house and lot in a city or village not exceeding $1500 in value, together with not less than $500 of his personal property—is exempt from execution. For several years previous to 1876 a clause of the constitution prohibited the sale of intoxicating liquors within the state. Since then the whole liquor business has been subjected to a heavy tax, and since 1887 the prohibition of it has been left to the option of each of the several counties. A state court of mediation and arbitration, consisting of three members appointed by the governor with the consent of the senate, was created in 1889 to inquire into the cause of grievances threatening or resulting in any strike or lock-out and to endeavour to effect a settlement.

Charitable and Penal Institutions.—The state supports the Michigan Asylum for the Insane (opened 1859), at Kalamazoo; the Eastern Michigan Asylum for the Insane (opened 1878), at Pontiac; the Northern Michigan Asylum for the Insane (opened 1885), at Traverse City; the Michigan Asylum for the Dangerous and Criminal Insane (established 1885), at Ionia; the Upper Peninsula Hospital for the Insane, at Newberry; a Psychopathic Hospital (established 1907), at Ann Arbor; a State Sanatorium (established 1905), at Howell; the Michigan State Prison (established 1839), at Jackson; the Michigan Reformatory (established 1887), at Ionia; the State House of Correction and Branch Prison (established 1885), at Marquette; the Industrial School for Boys, at Lansing; the Industrial Home for Girls (established 1879), near Adrian; the State Public School (opened 1874), at Coldwater, a temporary home for dependent children until homes in families can be found for them; the School for the Deaf (established 1854), at Flint; the School for the Blind, at Lansing; an Employment Institution for the Blind (established 1903), at Saginaw; the Home for the Feeble Minded and Epileptic (established 1893), at Lapeer; and the Michigan Soldiers' Home (established 1885), at Grand Rapids. Each of these institutions is under the control of a board of three or more members appointed by the governor with the approval of the Senate, and at the head of the department is the State Board of Corrections and Charities, consisting of the governor and four other members appointed by him, with the approval of the Senate, for a term of eight years, one retiring every two years. This board is required to visit each of the institutions at least once a year to ascertain its condition and needs, and all proposed appropriations for their support, plans of buildings, proposed systems of sewerage, ventilation and heating must be submitted to it.

Education.—Michigan was a pioneer state in creating the American educational system; she began the organization of it at the time of her admission into the Union in 1837, and has since been noted for the high standard of her schools. Each township operating under the District Act has two school inspectors—one being elected at each town meeting for a term of two years—who with the township clerk constitute the township board of school inspectors, and to this board is given authority to divide the township into school districts and to exercise a general supervision over the several schools within their jurisdiction; a township may be organized as a single district, called a "township unit district." The qualified electors of each district having an ungraded school elect a moderator, a director and a treasurer—one at each annual school meeting —for a term of three years, who constitute the district school board, and this board is entrusted with ample power for directing the affairs of the school. In a district having more than 100 children of school age a graded school under the control of five trustees is formed whenever two-thirds of the electors vote for it at a town meeting, and the trustees of a graded school may establish a high school whenever a majority of the electors authorize them to do so. A high school may also be established in any township in which there is no incorporated village or city if when the question is submitted to the electors of that township a majority of the votes cast are in the affirmative. Each county has a county school commissioner, elected for a term of four years, who exercises a general supervision over the schools within his jurisdiction, and a board of examiners, consisting of three members (including the commissioner) and appointed by the several boards of county supervisors, from whom teachers receive certificates. Finally, at the head of all the public elementary and secondary schools of the state is the state superintendent of public instruction, elected for a term of two years; he is *ex officio* a member and secretary of the state board of education, and a member, with the right to speak but not to vote, of all other boards having control of public instruction in any state institution. In every district having as many as 800 children between the ages of five and twenty the state requires that the school be taught not less than nine months a year; and a compulsory education law requires the attendance of all children between the ages of eight and fifteen for four months each year, in cities all between the same ages for the full school year, and between the ages of seven and sixteen if found frequenting public places without lawful occupation.

The higher state institutions of learning consist of a university, to which graduates of high schools on an accredited list are admitted without examination, four normal schools, an agricultural college, and a school of mines. The university (at Ann Arbor) was established in 1837, and is under the control of a board of regents elected by the people for a term of eight years, two every two years; the president of the institution and the superintendent of public instruction are members of the board but without the right to vote. The state normal schools are: the Michigan State Normal College at Ypsilanti (organized in 1849); the Central Michigan Normal School at Mount Pleasant (established in 1895); the Northern State Normal School at Marquette (established in 1899); and the Western State Normal School at Kalamazoo (established in 1904). All of them are under the state board of education, which consists of the state superintendent of public instruction and three other members elected, one every two years, for a term of six years. The agricultural college, at East Lansing, 3 m. east of Lansing, is the oldest in the United States; it was provided for by the state constitution of 1850, organized in 1855 and opened in 1857, and is under the control of the state board of agriculture, consisting of the president of the college and six other members elected by popular vote for a term of six years, two every two years. The college of mines, at Houghton, was established in 1885 and is under the control of a board of six members appointed by the governor with the approval of the Senate, two every two years. In 1908 it had 35 instructors, 253 students, and a library of 22,000 volumes. Other important institutions of learning within the state but not maintained by it are: Albion College (Methodist Episcopal; opened in 1843), at Albion; Hillsdale College (Free Baptist, 1855), at Hillsdale; Kalamazoo College (Baptist, 1855), at Kalamazoo; Adrian College (controlled by the Methodist Protestant Church since 1867), at Adrian; Olivet College (Congregational, 1859), at Olivet; Hope College (Reformed, 1866), at Holland; Detroit College (Roman Catholic, 1877), at Detroit; Alma College (Presbyterian; incorporated 1886), at Alma; and some professional schools at Detroit (*q.v.*).

Finance.—The revenue of the state is derived almost wholly from taxes, about 87% from a direct or general property tax and the rest from various specific or indirect taxes, such as the liquor tax and the inheritance tax. The direct tax, other than that on the property of corporations, is assessed by the township supervisors, or, in cities and incorporated villages by the officer named in the charter for that service, on what is supposed to be the full cash value of the property. The assessment roll thus prepared is reviewed by a local board of review; an equalization between the assessing districts in a county is made annually by the county board of supervisors, and between the counties in the state every five years (and at such other times as the legislature may direct) by the state board of equalization, which is composed of the lieutenant-governor, auditor-general, secretary of state, treasurer, and commissioner of the land office. But at the head of the whole taxing system is the board of state tax commissioners and *ex officio* state board of assessors, consisting of three members appointed by the governor with the approval of the senate for a term of six years. It exercises a general supervision over all other taxing officers and is itself the assessor of the property of railroads, express companies and certain car companies. Mainly through the efficiency of this board the assessed value of the taxable property of the state was increased from $968,189,087 in 1899 to $1,418,251,858 in 1902, or 46·4%, and the taxes levied on railways, which had hitherto been assessed on their gross earnings, were increased from $1,483,907 in 1901 to $3,288,162 in 1902, or 121·6%. In entering upon the work of public improvements in 1837 the state borrowed $5,200,000, and the greater portion of the bonds were sold to the Morris Canal and Banking Company and to the Pennsylvania United States Bank, both of which failed when they had only in part paid for the bonds. About this time it was seen that the cost of the improvements undertaken would be much greater than the original estimate and that several of them were impracticable. The difficulty of meeting the interest as it became due soon threatened to be insurmountable, but the state finally sold the improvements made and came out of the experience with good credit although with a large debt—about two and a half millions of dollars. This was further increased during the Civil War, but after the close of that war it was rapidly diminished and finally was extinguished in the last decade of the century. The present constitution (as revised in 1908) forbids the contraction of a state debt exceeding $250,000 except for repelling an invasion or suppressing an insurrection, and the borrowing power of the minor civil divisions is restricted by a general law.

The early experience of the state with banks was scarcely less serious than that with public improvements. Although there were already fifteen banks in the state in 1837 yet the cry against monopoly was loud, and so in that year a general banking law was passed whereby any ten or more freeholders might establish a bank with a capital of not less than fifty thousand nor more than three hundred thousand dollars and begin business as soon as 30% of the capital was paid in in specie. Only a few provisions were made, and those ineffectual, for the protection of the public: later in the same year the legislature passed an act for the suspension of specie payments until the 6th of May 1838, and the consequence was that the state was flooded with irredeemable paper currency. But most of the "wild cat" banks had passed out of existence by 1839, and in 1844 the bank act of 1837 was declared unconstitutional. Profiting by this experience, the framers of the constitution of 1850 inserted a provision in that document whereby no general banking law can have effect until it has been submitted to the people and has been approved by a majority of the votes cast on the question. This provision is included in the revised constitution adopted in 1908, with an additional provision that no amendment shall be made to any banking law unless it shall receive an affirmative two-thirds vote of both branches of the legislature. The present banking law provides that the capital stock of a state bank shall be not less than $20,000 in a city of not more than 1500 inhabitants, not less than $25,000 in a city of not more than 5000, not less than $50,000 in a city of between 5000 and 20,000, not less than $100,000 in a city of between 20,000 and 110,000, and not less than $250,000 in all larger cities. Commercial banks and savings banks are required to keep on hand at least 15% of their total deposits. Every stockholder in a bank is made individually liable to the amount of his stock at its par value in addition to the said stock. And all banks are subject to the inspection and supervision of the commissioner of the state banking department, who is appointed by the governor with the approval of the Senate for a term of four years.

History.—From 1613 until 1760 the territory now within the borders of Michigan formed a part of New France, and the first Europeans to found missions and settlements within those borders were Frenchmen. Two Jesuits, Raymbault and Jogues, visited the site of Sault Sainte Marie as early as 1641 for the conversion of the Chippewas; in 1668 Marquette founded there the first permanent settlement within the state; three years later he had founded a mission among the Hurons at Michilimackinac; La Salle built a fort at the mouth of the Saint Joseph in 1679; and in 1701 Cadillac founded Detroit as an important point for the French control of the fur trade. But the missionaries were not interested in the settlement of the country by Europeans, the fur traders were generally opposed to it, there was bitter strife between the missionaries and Cadillac, and the French system of absolutism in government and monopoly in trade were further obstacles to progress. Even Detroit was so expensive to the government of the mother country that there was occasional talk of abandoning it; and so during the last fifty-nine years that Michigan was a part of new France there were no new settlements, and little if any growth in those already established. During the last war between the English and the French in America the Michigan settlements passed into the possession of the English, Detroit in 1760 and the others in 1761, but the time had not yet come for much improvement. The white inhabitants, still mostly French, were subjected to an English rule that until the Quebec Act of 1774 was chiefly military, and as a consequence many of the more thrifty sought homes elsewhere, and the Indians, most of whom had been allies of the French, were so ill-treated, both by the officers and traders, that under Pontiac, chief of the Ottawas, a simultaneous attack on the English posts was planned. Detroit was besieged for five months and both Michilimackinac and Saint Joseph were taken. Moreover, the English policy, which first of all was concerned with the profits of trade and manufacture, gave little more encouragement to the settlement of this section of the country than did the French. By the Treaty of Paris, in 1783, which concluded the American War of Independence, the title to what is now Michigan passed to the United States, and in 1787 this region became a part of the North-West Territory; but it was not until 1796 that Detroit and Mackinac (Michilimackinac), in accordance with Jay's Treaty of 1794, were surrendered by Great Britain. In 1800, on the division of the North-West Territory, the west portion of Michigan became a part of the newly-established Indiana Territory, into which the entire area of the present state was embodied in 1802, when Ohio was admitted to the Union; and finally, in 1805, Michigan Territory was organized, its south boundary being then described as a line drawn east from the south extremity of Lake Michigan until it intersected Lake Erie, and its west boundary a line drawn from the same starting point through the middle of Lake Michigan to its north extremity and then due north to the north boundary of the United States. In 1812, during the second war between Great Britain and the United States, General William Hull, first governor of the Territory, although not greatly outnumbered, surrendered Detroit to the British without a struggle; in the same year also Mackinac was taken and Michigan again passed under British rule. This rule was of short duration, however, for soon after Commodore Oliver H. Perry's victory on Lake Erie, in September of the next year, Detroit and the rest of Michigan except Mackinac, which was not recaptured until July 1815, were again taken into the possession of the United States. Up to this time the Territory had still remained for the most part a wilderness in which the fur trade reaped the largest profits, its few small settlements being confined to the borders; and the inaccurate reports of the surveyors sent out by the national government described the interior as a vast swamp with only here and there a little land fit for cultivation. The large number of hostile Indians was also a factor in making the Territory unattractive. But during the efficient administration of Lewis Cass, governor of the Territory from 1813 to 1831, the interference of the British was checked and many of the Indians were removed to the west of the Mississippi; printing presses, established during the same period at Detroit, Ann Arbor, Monroe and Pontiac, became largely instrumental in making the country better known; the first steamboat, the "Walk-in-the-Water," appeared at Detroit in 1818; the Erie canal was opened in 1825; by 1830 a daily boat line was running between Detroit and Buffalo, and the population of Michigan, which was only 4762 in 1810 and 8896 in 1820, increased to 31,639 in 1830 and 212,267 in 1840. In 1819 the Territory had been empowered to send a delegate to Congress. By 1832 the question of admission into the Union had arisen, and in 1835 a convention was called in Detroit, a constitution was framed in May, that constitution was adopted by popular vote in October, state officers were elected, and application for admission was made; but a dispute with Ohio over the boundary between the two caused a delay in the admission by Congress until early in the year 1837. Although the ordinance creating the North-West Territory fixed the boundary line as claimed by Michigan, yet that line was found to be farther south than was at the time expected and when the constitution of Ohio was adopted it was accompanied with a proviso designed to secure to that state a north boundary that was north of the mouth of the Maumee River. The territory between the two proposed lines was unquestionably of greater economic importance to Ohio than to Michigan, and, besides, at this particular time there were forcible political reasons for not offending the older state. The consequence was that after the bloodless "war" between the two states for the possession of Toledo, Congress settled the dispute in Ohio's favour and gave to Michigan the territory since known as the upper peninsula. The boundaries as fixed by Congress were rejected by a convention which met on the 4th of September at Ann Arbor, but they were accepted by the convention of the Jackson party, which met, also at Ann Arbor, on the 6th of December; the action of this latter convention was considered authoritative by Congress, which admitted Michigan into the Union as a state on the 26th of January 1837. Since admission into the Union the more interesting experiences of the state have been with internal improvements and with banking, which together resulted in serious financial distress; in the utilization of its natural resources, which have been a vast source of wealth; and in the development of its educational system, in which the state has exerted a large influence throughout the Union. From the beginning of its government under its first state constitution in 1835 until 1855 Michigan had a Democratic administration with the exception of the years 1840–1842, when opposition to the financial measures of the Democrats placed the Whigs in power. But it was in Michigan that the Republican party received its first official recognition, at a state convention held at Jackson on the 6th of July 1857, and from the beginning of the following year the administration has been Republican with the exception of two terms from 1883 to 1885, and from 1891 to 1893, when it was again Democratic.

GOVERNORS OF MICHIGAN

	Territorial.	
William Hull		1805–1813
Lewis Cass		1813–1831
Stevens Thompson Mason (acting)		1831
George Bryan Porter		1831–1834
Stevens Thompson Mason (acting)		1834–1835
John Scott Horner (acting)		1835
	State.	
Stevens Thompson Mason	Democrat	1835–1840
William Woodbridge	Whig	1840–1841
James Wright Gordon (acting)	„	1841–1842
John Steward Barry	Democrat	1842–1846
Alpheus Felch	„	1846–1847
William L. Greenly (acting)	„	1847–1848
Epaphroditus Ransom	„	1848–1850
John Steward Barry	„	1850–1851
Robert McClelland	„	1851–1853
Andrew Parsons (acting)	„	1853–1855
Kinsley S. Bingham	Republican	1855–1859
Moses Wisner	„	1859–1861
Austin Blair	„	1861–1865
Henry Howland Crapo	„	1865–1869
Henry Porter Baldwin	„	1869–1873
John Judson Bagley	„	1873–1877
Charles Miller Croswell	„	1877–1881
David Howell Jerome	„	1881–1883
Josiah W. Begole	Democrat and Greenback	1883–1885
Russell Alexander Alger	Republican	1885–1887
Cyrus Gray Luce	„	1887–1891
Edwin Baruch Winans	Democrat	1891–1893
John T. Rich	Republican	1893–1897
Hazen Smith Pingree	„	1897–1901
Aaron Thomas Bliss	„	1901–1905
Fred M. Warner	„	1905–1911
Chase S. Osborn	„	1911

AUTHORITIES.—*The Publications of the Michigan Geological Survey* (Detroit, Lansing and New York, 1838 seq.) deal largely with the mining districts of the upper peninsula. Alexander Winchell, *Michigan: Being Condensed Popular Sketches of the Topography, Climate and Geology of the State* (1873), is in large measure restricted to the south half of the state. W. J. Beal and C. F. Wheeler, *Michigan Flora* (Lansing, 1892), contains the results of an extensive study of the subject. See also the *Twelfth Census of the United States* (Washington, 1901–1902); Silas Farmer, *Michigan Book: a State Cyclopaedia with Sectional County Maps* (Detroit, 1901); Bela Hubbard, *Memorials of a Half-Century* (New York, 1887), a well written account of observations, chiefly upon scenery, fauna, flora and climate; Webster Cook, *Michigan: its History and Government* (New York, 1905), written primarily for use in schools and containing a reference bibliography; A. C. McLaughlin, *History of Higher Education in Michigan*, in Circulars of Information of the United States Bureau of Education (Washington, 1891), being an account of the origin of the public school system and an individual account of each higher institution of learning; T. M. Cooley, *Michigan: a History of Government* (Boston, 1885), a critical but popular narrative by an eminent jurist; J. V. Campbell, *Outlines of the Political History of Michigan* (Detroit, 1876), also by a jurist of the state; Henry M. Utley and Byron M. Cutcheon, *Michigan as a Province, Territory and State* (4 vols., New York, 1906); Michigan Pioneer and Historical Society, *Historical Collections: Collections and Researches* (Lansing, 1877 seq.); and *Publications of the Michigan Political Science Association* (Ann Arbor, 1893).

MICHIGAN, LAKE, the only one of the great lakes of North America wholly within the boundaries of the United States, and the second largest body of fresh water in the world. It lies S. of Lake Superior and W. of Lake Huron, between 41° 37′ and 46° 05′ N. and 84° 45′ and 88° W.; is bounded on the N. and E. by the state of Michigan, on the W. by Wisconsin, while Illinois and Indiana touch its S. end. It is 320 m. long, and has an average width of 65 m. The maximum depth recorded by the United States Lake Survey is 870 ft.; the mean level of the surface is $581\frac{1}{3}$ ft. above mean sea-level, being the same as that of Lake Huron and 21 ft. below that of Lake Superior. Its area is 22,400 sq. m., and it has a basin 68,100 sq. m. in area.

The shores of Lake Michigan are generally low and sandy, and the land slopes gradually to the water. The northern shore of the lake is irregular and more rugged and picturesque than the other shores, the summit of the highest peak being about 1400 ft. above the sea. On the eastern side are numerous sand hills, formed by the wind into innumerable fantastic shapes, sometimes covered with stunted trees and scanty vegetation, but usually bare and rising to heights of from 150 to 250 ft. The south-western shore is generally low, with sand hills covered with shrivelled pines and bur oaks. Along the western shore woods and prairies alternate, interspersed with a few high peaks. The cliffs on the east shore of Green Bay form a bold escarpment, and from this ridge the land slopes gradually to the lake. With the exception of Green and Traverse bays, Lake Michigan has few indentations of the coast line, and except at the north end it is free from islands. The waters near shore are shoal, and as there are few harbours of refuge of easy access navigation is dangerous in heavy storms. Around the lake the climate is equable, for, though the winter is cold and the summer hot, the waters of the lake modify the extremes, the mean temperature varying from 40° to 54° F. The average annual rainfall is 33 in. The finest agricultural land in the United States is near the lake, and there is an immense trade in all grains, fruits, livestock and lumber, and in products such as flour, pork, hides, leather goods, furniture, &c. Rich lead and copper mines abound, as also salt, iron and coal. Abundant water power promotes manufactures of all kinds. Beer and distilled liquors are largely manufactured, and fine building stone is obtained from numerous quarries.

The lake is practically tideless, though true tidal pulsations amounting to 3 in. in height are stated to have been observed in Chicago. In the water of the lake there is a general set of current towards the outlet at the strait of Mackinac, following the east shore, with slight circular currents in the main portion of the lake and at the northern end around Beaver island. These currents vary in speed from 4 to 10 m. per day. Surface currents are set up by prevailing winds, which also seriously affect water levels, lowering the water at Chicago and raising it at the strait, or the reverse, so as greatly to inconvenience navigation. The level of the lake is subject to seasonal fluctuations, reaching a maximum in midsummer and a minimum in February, as well as to alternating cycles of years of high and low water. Standard high-water of 1838 was 3·36 ft. above mean level and standard low-water of 1895, 2·82 ft. below that datum, giving an extreme recorded range slightly over 6 ft.

The northern portion of the lake only is covered with ice in winter, and ice never reaches as far south as Milwaukee. Milwaukee River remains closed on an average for one hundred days—from the beginning of December to the middle of March. The average date of the opening and closing of navigation at the strait of Mackinac, where the ice remains longest, is the 17th of April and the 9th of January respectively.[1] Regular lines of steamers specially equipped to meet winter conditions, most of them being car ferries, cross the lake and the strait of Mackinac all winter between the various ports.

No notable rivers flow into Lake Michigan, the largest being the Big Manistee and Muskegon on the east shore, and on the west shore the Menominee and the Fox, both of which empty into Green Bay, the most important arm of the lake. The numerous harbours are chiefly artificial, usually located at the mouths of streams, the improvements consisting of two parallel piers extending into the lake and protecting a dredged channel. Sand bars keep filling up the mouths of these channels, necessitating frequent dredging and extension of the breakwaters, work undertaken by the Federal government, which also maintains a most comprehensive and complete system of aids to navigation, including lighthouses and lightships, fog alarms, gas and other buoys, life-saving, storm signal and weather report stations.

---

[1] *Report of Deep Waterways Commission* (1896).

Chicago, the principal port on the lake, is at its south-west extremity, and is remarkable for the volume of its trade, the number of vessels arriving and departing exceeding that of any port in the United States, though the tonnage is less than that of New York. It is a large railway centre, and the number and size of the grain elevators are noticeable. The port is protected by breakwaters enclosing a portion of the lake front. The level of the city above the lake being only 14 ft., much difficulty arose in draining it. A sanitary and ship canal 34 m. long was therefore completed in 1900 to divert the Chicago river, a small stream that flows into the lake, into the head waters of the Des Plaines river and thence through the river Joliet into the Mississippi at St Louis. The discharge of water is by law so regulated that the maximum flow shall not exceed 250,000 cub. ft. per minute. The effect upon the permanent level of the lakes of the withdrawal of water through this artificial outlet is receiving much attention. Milwaukee, situated on the shore of Milwaukee Bay, on the western side of the lake, is, next to Chicago, the largest city on the lake, and has a large commerce and a harbour of refuge. Escanaba, on Little Bay de Noc (Noquette), in the northern part of the lake, is a natural harbour and a large iron shipping port. Green Bay and Lake Michigan are connected by a canal extending from the lake to the head of Sturgeon Bay. Lake Michigan is connected at its north-east extremity with lake Huron by the strait of Mackinac, 48 m. long, with a minimum width of 6 m.; the water is generally deep and the shoals lying near the usually travelled routes are well marked.

MICHIGAN, UNIVERSITY OF, one of the principal educational institutions of the United States, situated at Ann Arbor, Michigan. It embraces a department of literature, science and the arts (including industry and commerce), opened in 1841, and including a graduate school, organized in 1892; a department of medicine and surgery, opened in 1850; a department of law, opened in 1859; a school of pharmacy, opened as a separate department in 1876; a homoeopathic medical college, opened in 1875; a college of dental surgery, opened in 1875; and a department of engineering, separately organized in 1895, which includes courses in marine engineering, architecture, and architectural engineering. The university was one of the first to admit women, having opened its doors to them in 1870 as a natural consequence of its receiving aid from the state (since 1867), and since 1900 they have constituted nearly one-half of the student body in the department of literature, science and the arts. In 1907–1908 there were in all departments 350 instructors and 5013 students (1796 in the department of literature, science and the arts; 1354 in the department of engineering; 391 in the department of medicine and surgery; 791 in the department of law; 101 in the school of pharmacy; 82 in the homoeopathic medical college; 168 in the college of dental surgery; and 1070 in the summer sessions). Besides the several main department buildings there is a library building, a museum building, several laboratories, a gymnasium for men, and a gymnasium for women. The general library in 1908 contained 172,940 volumes, 3800 pamphlets, and 3370 maps, and the several department libraries brought the total up to 222,600 volumes and 5000 pamphlets. The general museum contains large zoological collections, geological and anthropological collections, including the exhibit of the Chinese government at the New Orleans Exposition, which was given by the government to the university in 1885; there are besides several special collections in some of the laboratories. The astronomical observatory is surmounted by a movable dome in which is mounted a refracting telescope having a thirteen-inch object glass. The several laboratories are equipped for use in instruction in physics, chemistry, mineralogy, geology, zoology, psychology, botany, forestry, actuarial work, engineering, histology, physiology, hygiene, electrotherapeutics, pathology, anatomy and dentistry.

The university is governed from without by a board of eight regents elected by popular suffrage, two biennially, at the same time as the election of judges of the supreme court; from within the government is to a large extent in the hands of a university senate, in which the faculty of each department is represented. The university is maintained by a permanent annuity of $30,000, derived from the land set apart for it by the Ordinance of 1787, by the proceeds of a three-eighths mill tax, and by small fees paid by the students. Its organic relation to the other public schools of the state was well established in 1870, when it was provided that graduates from such high schools as had been examined and approved by a committee of the university should be admitted without examination; one of the most important functions of the university is to prepare students for teaching in the high schools.

The first charter for a university within what is now the state was granted by the governor and judges of the Territory of Michigan in 1817, for a "Catholepistemiad," or University of Michigania, with a remarkable "Greek" system of nomenclature for its courses and faculties; this institution did practically no teaching. A second charter was granted in 1821, for a University of Michigan in Detroit; but little was accomplished until the admission of Michigan into the Union as a state in 1837, when by the third charter the aim was to model the institution after the German university minus the theological department, and the university was entrusted to a board of regents and a chancellor appointed by the governor. Branches to correspond to the German gymnasia were established in the principal towns before any money was spent on the University proper, but the question of the constitutionality of their establishment and maintenance arose, and they were soon discontinued. Plans for building at Ann Arbor were begun in 1838. The first class graduated in 1845. The department of literature, science and the arts was at first much like a New England college. For some time the prospects did not seem promising; but in 1851 a new state constitution provided that the regents should be elected, and directed them to choose a president; and it was under the administration (1852–1863) of the first incumbent of that office, Henry Philip Tappan (1805–1881), that the present broad and liberal basis was established. Although he was a Presbyterian clergyman, he endeavoured at the outset to substitute the tests of scholarship for those of religion; at the same time a scientific course was introduced, courses in pedagogy followed, and in 1878 the elective system, which has since rapidly expanded, was established. President Tappan was succeeded in 1863 by Erastus Otis Haven (1820–1881), who resigned in 1869, and was succeeded temporarily (1869–1871) by Professor Henry S. Frieze (1817–1889), and in 1871 by James Burrill Angell (b. 1829),[1] who resigned in 1909. In 1871–1872 the German seminar method was introduced in graduate work in history, by Prof. Charles Kendall Adams (1835–1902), afterwards president of Cornell University (1885–1892) and of the University of Wisconsin (1892–1902).

See B. A. Hinsdale and I. N. Demmon, *History of the University of Michigan* (Ann Arbor, 1906); Elizabeth M. Farrand, *History of the University of Michigan* (Ann Arbor, 1885); and *The Quarter Centennial of the Presidency of James Burrill Angell* (Ann Arbor, 1896).

MICHIGAN CITY, a city of Laporte county, Indiana, U.S.A., on the S.E. shore of lake Michigan, about 40 m. E. by S. of Chicago. Pop. (1890) 10,776; (1900), 14,850, of whom 3662 were foreign-born; (1910 census) 19,027. Michigan City is served by the Chicago, Indianapolis & Louisville, the Lake Erie & Western, the Michigan Central and the Père Marquette railways, by interurban electric lines, and by several lines of lake steamships. The city contains a United States Life Saving Station and the Indiana State Prison, and is the seat of a Protestant Episcopal bishop. Its transportation advantages make it one of the principal commercial cities in the state. Its shipments of lumber are of special importance, and it has also a large transshipment trade in salt and iron ore. The total factory product in 1905 was valued at $6,314,226. The municipality owns and operates its water-works system. Michigan City was first settled about 1830, was incorporated as a village in 1837, and was first chartered as a city in 1867.

---

[1] President Angell graduated in 1849 at Brown University, where he was assistant librarian in 1849–1850 and was professor of modern languages in 1853–1860; was editor of the Providence *Journal* in 1860–1866; was president of the University of Vermont in 1866–1871, was United States minister to China in 1880–1881, was a member of the joint commission of 1887–1888 to settle fishery disputes between the United States and Great Britain, was chairman of the international deep waterways commission in 1896, and in 1897–1898 was United States minister to Turkey.

MICHMASH, a place in Benjamin, about 9 Roman miles north of Jerusalem (*Onom*, ed. Lag., p. 280), the scene of one of the most striking episodes in Old Testament history (1 Sam. xiv.). Though it did not rank as a city (not being mentioned in Joshua xviii. 21 seq.), Michmash was recolonized after the exile (Neh. xi. 31), and, favoured by the possession of excellent wheat-land (*Mishna*, Men. viii. 1), was still a very large village (Μαχμάς) in the time of Eusebius. The modern Mukhmas is quite a small place.

The historical interest of Michmash is connected with the strategical importance of the position, commanding the north side of the Pass of Michmash, which made it the headquarters of the Philistines and the centre of their forays in their attempt to quell the first rising under Saul, as it was also at a later date the headquarters of Jonathan the Hasmonaean (1 Macc. ix. 73). From Jerusalem to Mount Ephraim there are two main routes. The present caravan road keeps the high ground to the west near the watershed, and avoids the Pass of Michmash altogether. But another route, the importance of which in antiquity may be judged of from Isa. x. 28 sqq., led southwards from Ai over an undulating plateau to Michmash. Thus far the road is easy, but at Michmash it descends into a very steep and rough valley, which has to be crossed before reascending to Geba.[1] At the bottom of the valley is the Pass of Michmash, a noble gorge with precipitous craggy sides. On the north the crag is crowned by a sort of plateau sloping backwards into a round-topped hill. This little plateau, about a mile east of the present village of Mukhmas, seems to have been the post of the Philistines, lying close to the centre of the insurrection, yet possessing unusually good communication with their establishments on Mount Ephraim by way of Ai and Bethel, and at the same time commanding the routes leading down to the Jordan from Ai and from Michmash itself.

MICHOACÁN, or MICHOACÁN DE OCAMPO, a state of Mexico touching on the Pacific, bounded N. by Jalisco and Guanajuato, E. by Mexico and Guerrero, S. by Guerrero and the Pacific, and W. by the Pacific, Colima, and Jalisco. Pop. (1900), 935,808, chiefly Indians and mestizos. Area, 22,874 sq. m. Its territory is divided into two nearly equal parts by the eastern branch of the Sierra Madre Occidental, the northern part belonging to the great central plateau region, and the southern to an extremely broken region formed by the diverging branches of the Sierra Madre, with their wooded terraces and slopes and highly fertile valleys. The general slope of the southern part is southward to the river Balsas, or Mescala, which forms its boundary-line with Guerrero. The narrow coastal zone on the Pacific is only 101 m. long and has no ports or towns of importance, the slopes of the Sierra Madre del Pacifico being precipitous and heavily wooded and the coast-belt sandy, hot and malarial. The Lerma, on the northern frontier, and the Balsas on the southern, are the only rivers of importance of the state, their tributaries within its boundaries being small and swift-flowing. There are several large and beautiful lakes in the state, the best known of which are Patzcuaro and Cuitzéo. Lake Chapala lies on the northern boundary. Michoacán lies within the most active volcanic region of Mexico: Jorullo (4262 ft.) is near its southern line, and Colima (12,750 ft.) is northwest of it in the state of Jalisco. Earthquake shocks are numerous, and Colima was in violent eruption in 1908–1909. The highest summit in the state is Tancitaro (12,660 ft.). The climate is for the most part temperate and healthy, but it is hot and unhealthy on the coast. Michoacán is essentially a mining region, producing gold, silver, lead and cinnabar, and having rich deposits of copper, coal, petroleum and sulphur. The natural products include fine cabinet and construction woods, rubber, fruit, palm oil and fibres. The soil of the valleys is highly fertile, and produces cereals in the higher regions, and sugar-cane, tobacco, coffee and tropical fruits in the lower. Though the plateau region was settled soon after the arrival of the Spaniards in Mexico, there are large districts on the southern and Pacific slopes that still belong almost exclusively to the Indians. Besides Morelia, the capital and largest city, the principal towns of the state are: La Piedad (pop. 15,123), an important commercial town on the Lerma river and on the Mexican Central railway, 112 m. N.N.W. of Morelia; Zamora (10,373), 75 m. W.N.W. of Morelia; Uruapan (9808), on the Mexican National, 55 m. S.W. of Morelia in a mountainous district celebrated for the fine quality of its coffee; Puruandiro (7782), a commercial and manufacturing town 40 m. N.W. of Morelia; Patzcuaro (7621), on Patzcuaro lake, with a station on the Mexican National, 7550 ft. above sea level; Sahuayo (7408), 103 m. W. by N. of Morelia near Lake Chapala; Zitacuaro (6052), 60 m. S.E. of Morelia on a branch of the Mexican National, which also passes through the mining town of Angangueo (9115) in the same district; and Tacambaro (5070), 46 m. S.S.W. of Morelia in a fertile valley of the Rio de las Balsas basin.

MICKIEWICZ, ADAM (1798–1855), Polish poet, was born in 1798, near Nowogrodek, in the present Russian government of Minsk, where his father, who belonged to the schlachta or lesser nobility, had a small property. The poet was educated at the university of Vilna; but, becoming involved in some political troubles there, he was forced to terminate his studies abruptly, and was ordered to live for a time in Russia. He had already published two small volumes of miscellaneous poetry at Vilna, which had been favourably received by the Slavonic public, and on his arrival at St Petersburg he found himself admitted to the leading literary circles, where he was a great favourite both from his agreeable manners and his extraordinary talent of improvisation. In 1825 he visited the Crimea, which inspired a collection of sonnets in which we may admire both the elegance of the rhythm and the rich Oriental colouring. The most beautiful are *The Storm*, *Bakchiserai*, and *Grave of the Countess Potocka*.

In 1828 appeared his *Konrad Wallenrod*, a narrative poem describing the battles of knights of the Teutonic order with the heathen Lithuanians. Here, under a thin veil, Mickiewicz represented the sanguinary passages of arms and burning hatred which had characterized the long feuds of the Russians and Poles. The objects of the poem, although evident to many, escaped the Russian censors, and it was suffered to appear, although the very motto, taken from Machiavelli, was significant: "Dovete adunque sapere come sono duo generazioni da combattere . . . bisogna essere volpe e leone." This is a striking poem and contains two beautiful lyrics. After a five years' exile in Russia the poet obtained leave to travel; he had secretly made up his mind never to return to that country or Poland so long as it remained under the government of the Muscovites. Wending his way to Weimar, he there made the acquaintance of Goethe, who received him cordially, and, pursuing his journey through Germany, he entered Italy by the Splügen, visited Milan, Venice, and Florence, and finally took up his abode at Rome. There he wrote the third part of his poem *Dziady*, the subject of which is the religious commemoration of their ancestors practised among Slavonic nations, and *Pan Tadeusz*, his longest poem, by many considered his masterpiece. A graphic picture is drawn of Lithuania on the eve of Napoleon's expedition to Russia in 1812. In this village idyll, as Brückner calls it, Mickiewicz gives us a picture of the homes of the Polish magnates, with their somewhat boisterous but very genuine hospitality. We see them before us, just as the knell of their nationalism, as Brückner says, seemed to be sounding, and therefore there is something melancholy and dirge-like in the poem in spite of the pretty love story which forms the main incident. Mickiewicz turned to Lithuania with the loving eyes of an exile, and gives us some of the most delightful descriptions of Lithuanian skies and Lithuanian forests. He describes the weird sounds to be heard in the primeval woods in a country where the trees were sacred. The cloud-pictures are equally striking. There is nothing finer in Shelley or Wordsworth.

---

[1] So Isa. x. 28 describes the invader as leaving his heavy baggage at Michmash before pushing on through the pass.

In 1832 Mickiewicz left Rome for Paris, where his life was for some time spent in poverty and unhappiness. He had married a Polish lady, Selina Szymanowska, who became insane. In 1840 he was appointed to the newly founded chair of Slavonic languages and literature in the Collège de France, a post which he was especially qualified to fill, as he was now the chief representative of Slavonic literature, Pushkin having died in 1837. He was, however, only destined to hold it for a little more than three years, his last lecture having been given on the 28th of May 1844. His mind had become more and more disordered under the influence of religious mysticism. He had fallen under the influence of a strange fanatic named Towianski. His lectures became a medley of religion and politics, and thus brought him under the censure of the Government. A selection of them has been published in four volumes. They contain some good sound criticism, but the philological part is very defective, for Mickiewicz was no scholar, and he is obviously only well acquainted with two of the literatures, viz. Polish and Russian, the latter only till the year 1830. A very sad picture of his declining days is given in the memoirs of Herzen. At a comparatively early period the unfortunate poet exhibited all the signs of premature old age; poverty, despair and domestic affliction had wrought their work upon him. In 1849 he founded a French newspaper, *La Tribune des peuples*, but it only existed a year. The restoration of the French Empire seemed to kindle his hopes afresh; his last composition is said to have been a Latin ode in honour of Napoleon III. On the outbreak of the Crimean War he was sent to Constantinople to assist in raising a regiment of Poles to take service against the Russians. He died suddenly there in 1855, and his body was removed to France and buried at Montmorency. In 1900 his remains were disinterred and buried in the cathedral of Cracow, the Santa Croce of Poland, where rest, besides many of the kings, the greatest of her worthies.

Mickiewicz is held to have been the greatest Slavonic poet, with the exception of Pushkin. Unfortunately in other parts of Europe he is but little known; he writes in a very difficult language, and one which it is not the fashion to learn. There were both pathos and irony in the expression used by a Polish lady to a foreigner, "Nous avons notre Mickiewicz à nous." He is one of the best products of the so-called romantic school. The Poles had long groaned under the yoke of the classicists, and the country was full of legends and picturesque stories which only awaited the coming poet to put them into shape. Hence the great popularity among his countrymen of his ballads, each of them being connected with some national tradition. Besides *Konrad Wallenrod* and *Pan Tadeusz*, attention may be called to the poem *Grazyna*, which describes the adventures of a Lithuanian chieftainess against the Teutonic knights. It is said by Ostrowski to have inspired the brave Emilia Plater, who was the heroine of the rebellion of 1830, and after having fought in the ranks of the insurgents, found a grave in the forests of Lithuania. A fine vigorous Oriental piece is *Farys*. Very good too are the odes to Youth and to the historian Lelewel; the former did much to stimulate the efforts of the Poles to shake off their Russian conquerors. It is enough to say of Mickiewicz that he has obtained the proud position of the representative poet of his country; her customs, her superstitions, her history, her struggles are reflected in his works. It is the great voice of Poland appealing to the nations in her agony.

His son, Ladislas Mickiewicz, wrote *Vie d'Adam Mickiewicz* (Posen, 1890–1895, 4 vols.), also *Adam Mickiewicz, sa vie et son œuvre* (Paris, 1888). Translations into English (1881–1885) of *Konrad Wallenrod* and *Pan Tadeusz* were made by Miss Biggs. See also *Œuvres poétiques de Mickiewicz*, trans. by Christien Ostrowski (Paris, 1845). (W. R. M.)

MICKLE, WILLIAM JULIUS (1735–1788), Scottish poet, son of the minister of Langholm, Dumfries-shire, was born on the 28th of September 1735. He was educated at the Edinburgh high school, and in his fifteenth year entered business as a brewer. His father purchased the business, and on his death William Mickle became the owner; but he neglected his affairs, devoting his time to literature, and before long became bankrupt. In 1763 he went to London, where in 1765 he published "a poem in the manner of Spenser" called the *Concubine* (afterwards *Syr Martyn*); was appointed corrector to the Clarendon Press, and translated the *Lusiad* of Camoens into heroic couplets (specimen published 1771, whole work, 1775). So great was the repute of this translation that when Mickle—appointed secretary to Commodore Johnstone—visited Lisbon in 1779, the king of Portugal gave him a public reception. On his return to London he was appointed one of the agents responsible for the distribution of prize-money, and this employment, in addition to the sums brought him by his translation of the Lusiad, placed him in comfortable circumstances.

It has been suggested that the Scottish poem "There's nae luck aboot the hoose" was Mickle's. It is more likely, however, that Jean Adams was the author. Scott read and admired Mickle's poems in his youth, and founded *Kenilworth* on his ballad of *Cumnor Hall*, which appeared in Thomas Evans's *Old Ballads . . . with some of Modern Date* (1784).

MICMAC, a tribe of North American Indians of Algonquian stock. They formerly occupied all Nova Scotia, Cape Breton and Prince Edward Islands, and portions of New Brunswick, Quebec and Newfoundland. They fought on the French side in the colonial wars. They are now civilized and almost all profess Catholicism. They number some 4000 in settled communities throughout their former territory.

There is an excellent account of the Micmac Indians in J. G. Millais's *Newfoundland and its Untrodden Ways* (1908).

MICON, a Greek painter of the middle of the fifth century B.C. He was closely associated with Polygnotus of Thasos, in conjunction with whom he adorned the Painted Stoa, at Athens, with paintings of the battle of Marathon and other battles. He also painted in the Anaceum at Athens.

MICROCLINE, a rock-forming mineral belonging to the feldspar group (see FELSPAR). Like orthoclase it is a potash-feldspar with the formula $KAlSi_3O_8$, but differs from this in crystallizing in the anorthic system. The name (from Greek *μικρός*, small, and *κλίνειν*, to incline) was given by A. Breithaupt in 1830, and has reference to the fact that the angle (89° 30′) between the two perfect cleavages differs but little from a right angle: the species was, however, first definitely established by A. Des Cloizeaux in 1876. The crystals and cleavage masses are very like orthoclase in appearance, and the hardness (6) and specific gravity (2·56) are the same for the two minerals; there are, however, important differences in the twinning and in the optical characters. In addition to being twinned according to the same laws as orthoclase, microcline is repeatedly twinned according to the albite-law and the pericline-law, producing a very characteristic grating or cross-hatched structure which is especially prominent when thin sections of the mineral are examined in polarized light. This lamellar structure is often on a very minute scale, sometimes so minute as to be almost indistinguishable: it has therefore been suggested that orthoclase is really a microcline in which the twin-lamellae are ultra-microscopic. In a section parallel to the basal plane *c* (001) of a microcline crystal the lamellae do not extinguish optically parallel to the edge *bc* as in orthoclase, but at an angle of 15° 30′; further, the obtuse bisectrix of the optic axes in microcline is inclined to the normal of the plane *b* (010) at an angle of 15° 26′. Green microcline is distinctly pleochroic.

Microcline occurs, usually with orthoclase, as a constituent of pegmatites, granites and gneisses; it is rare in porphyries and is not known in volcanic rocks. A beautiful crystallized variety of a bright verdigris-green colour is known as amazon-stone (*q.v.*). Chesterlite is a variety occurring as crystals on dolomite in Chester county, Pennsylvania.

Closely allied to microcline is the anorthic soda-potash-feldspar known as anorthoclase or natron-microcline. Here sodium predominates over potassium and a little calcium is also often present, the formula being $(Na, K)\,AlSi_3O_8$. It resembles microcline in having a cleavage angle of very nearly 90° and in the cross-hatched structure, the latter being usually very minute and giving rise to a mottled extinction. It is the characteristic feldspar of volcanic rocks which are rich in soda, and is typically developed in the lavas of the island of Pantelleria near Sicily and those of Kilimanjaro and Mount Kenya in East Africa: the rhomb-shaped porphyritic feldspars of the "rhomb-porphyry" of southern Norway also belong here.

(L. J. S.)

MICROCOSM, a term often applied in philosophical and in general literature to man regarded as a "little world" (Gr. *μικρός κόσμος*) in opposition to the "macrocosm," great world, in which he lives. From the dawn of speculative thought in Greece the analogy between man and the world has been a common-place, and may be traced from Heraclitus and Empedocles, through Plato, Aristotle, the Stoics, the Schoolmen and the thinkers of the Renaissance down to the present day. Thus Lotze's comprehensive survey of mental and moral science is termed *Microcosmus* The most systematic expression of the tendency indicated by the term is the monadology of Leibnitz, in which the monad is regarded as containing within its own closed sphere an expression of the universe, the typical created monad being the human soul.

MICROCOSMIC SALT, or ammonium sodium hydrogen orthophosphate, $NH_4NaHPO_4 \cdot 4H_2O$, so named by the alchemists because it is contained in the decomposing urine of man (the "microcosm"). It is interesting historically as being the raw material from which Brand prepared phosphorus, whence it is also called "salt of phosphorus." It may be obtained in large transparent crystals from a mixture of solutions of salammoniac and disodium phosphate, or by saturating a solution of monosodium phosphate with ammonia. When heated to redness, it leaves a transparent glass of sodium metaphosphate, $NaPO_3$, which like borax dissolves most metallic oxides, with formation of glasses that often exhibit characteristic colours, and which may be used in the qualitative analysis of substances. (See CHEMISTRY, § *Analytical.*)

MICROMETER (from Gr. *μικρός*, small, *μέτρον*, a measure), an instrument generally applied to telescopes and microscopes for measuring small angular distances with the former or the dimensions of small objects with the latter.

Before the invention of the telescope the accuracy of astronomical observations was necessarily limited by the angle that could be distinguished by the naked eye. The angle between two objects, such as stars or the opposite limbs of the sun, was measured by directing an arm furnished with fine "sights" (in the sense of the "sights" of a rifle) first upon one of the objects and then upon the other (*q.v.*), or by employing an instrument having two arms, each furnished with a pair of sights, and directing one pair of sights upon one object and the second pair upon the other. The angle through which the arm was moved, or, in the latter case, the angle between the two arms, was read off upon a finely graduated arc. With such means no very high accuracy was possible. Archimedes concluded from his measurements that the sun's diameter was greater than 27′ and less than 32′; and even Tycho Brahe was so misled by his measures of the apparent diameters of the sun and moon as to conclude that a total eclipse of the sun was impossible.[1] Michael Maestlin in 1579 determined the relative positions of eleven stars in the Pleiades (*Historia coelestis Lucii Baretti*, Augsburg, 1666), and A. Winnecke has shown (*Monthly Notices R.A.S.*, xxxix. 146) that the probable error of these measures amounted to about ± 2′.[2]

The invention of the telescope at once extended the possibilities of accuracy in astronomical measurements. The planets were shown to have visible disks, and to be attended by satellites whose distance and position angle relative to the planet it was desirable to measure. It became, in fact, essential to invent a "micrometer" for measuring the small angles which were thus for the first time rendered sensible. There is now no doubt that William Gascoigne, a young gentleman of Yorkshire, was the first inventor of the micrometer. William Crabtree, a friend of his, taking a journey to Yorkshire in 1639 to see Gascoigne, writes thus to his friend Jeremiah Horrocks. "The first thing Mr Gascoigne showed me was a large telescope amplified and adorned with inventions of his own, whereby he can take the diameters of the sun and moon, or any small angle in the heavens or upon the earth, most exactly through the glass, to a second." The micrometer so mentioned fell into the possession of Richard Townley of Lancashire, who exhibited it at the meeting of the Royal Society held on the 25th of July 1667.

The principle of Gascoigne's micrometer is that two pointers having parallel edges at right angles to the measuring screw, are moved in opposite directions symmetrically with and at right angles to the axis of the telescope. The micrometer is at zero when the two edges are brought exactly together. The edges are then separated till they are tangent to the opposite limbs of the disk of the planet to be measured, or till they respectively bisect two stars, the angle between which is to be determined. The symmetrical separation of the edges is produced and measured by a single screw; the fractions of a revolution of the screw are obtained by an index attached to one end of the screw, reading on a dial divided into 100 equal parts. The whole arrangement is elegant and ingenious. A steel cylinder (about the thickness of a goose-quill), which forms the micrometer screw, has two threads cut upon it, one-half being cut with a thread double the pitch of the other. This screw is mounted on an oblong box which carries one of the measuring edges; the other edge is moved by the coarser part of the screw relatively to the edge attached to the box, whilst the box itself is moved relatively to the axis of the telescope by the finer screw. This produces an opening and closing of the edges symmetrically with respect to the telescope axis. Flamsteed, in the first volume of the *Historia coelestis*, has inserted a series of measurements made by Gascoigne extending from 1638 to 1643. These include the mutual distances of some of the stars in the Pleiades, a few observations of the apparent diameter of the sun, others of the distance of the moon from neighbouring stars, and a great number of measurements of the diameter of the moon. Dr John Bevis (*Phil. Trans.* (1773), p. 190) also gives results of measurements by Gascoigne of the diameters of the moon, Jupiter, Mars and Venus with his micrometer.

Delambre gives[3] the following comparison between the results of Gascoigne's measurements of the sun's semi-diameter and the computed results from modern determinations:—

			Gascoigne.	*Conn. d. temps.*
October	25	(o.s.)	16′ 11″ or 10″	16′ 10″·0
,,	31	,, ...	16′ 11″	16′ 11″·4
December	2	,, ...	16′ 24″	16′ 16″·8

Gascoigne, from his observations, deduces the greatest variation of the apparent diameter of the sun to be 35″; according to the *Connaissance des temps* it amounts to 32″·3.[3] These results prove the enormous advance attained in accuracy by Gascoigne, and his indisputable title to the credit of inventing the micrometer.

Huygens, in his *Systema saturnium* (1659), describes a micrometer with which he determined the apparent diameters of the principal planets. He inserted a slip of metal, of variable breadth, at the focus of the telescope, and observed at what part it exactly covered the object under examination; knowing the focal length of the telescope and the width of the slip at the point observed, he thence deduced the apparent angular breadth of the object. The Marquis Malvasia in his *Ephemerides* (Bologna, 1662) describes a micrometer of his own invention. At the focus of his telescope he placed fine silver wires at right angles to each other, which, by their intersection, formed a network of small squares. The mutual distances of the intersecting wires he determined by counting, with the aid of a pendulum clock, the number of seconds required by an equatorial star to pass from web to web, while the telescope was adjusted so that the star ran parallel to the wires at right angles to those under investigation.[4] In the *Phil. Trans.* (1667), No. 21, p. 373, Adrien Auzout gives the results of some measures of the diameter of the sun and moon made by himself, and this communication led to the letters of Townley and Bevis above referred to. The micrometer of Auzout and Picard was provided with silk fibres or silver wires instead of the edges of Gascoigne, but one of the silk fibres remained fixed while the other was moved by a screw. It is beyond doubt that Huygens independently discovered that an object placed in the common focus of the two lenses of a Kepler telescope appears as distinct and well-defined as the image of a distant body; and the micrometers of Malvasia, Auzout and Picard are the natural developments of this discovery. Gascoigne was killed at the battle of Marston Moor on the 2nd of July 1644, in the twenty-fourth year of his age, and his untimely death was doubtless the cause that delayed the publication of a discovery which anticipated, by twenty years, the combined work of Huygens, Malvaison, Auzout and Picard in the same direction.

---

[1] Grant, *History of Physical Astronomy*, p. 449.

[2] This is an astonishing accuracy when the difficulty of the objects is considered. Few persons can see with the naked eye—much less measure—more than six stars of the Pleiades, although all the stars measured by Maestlin have been seen with the naked eye by a few individuals of exceptional powers of eyesight.

Spider Web.

As the powers of the telescope were gradually developed, it was found that the finest hairs or filaments of silk, or the thinnest silver wires that could be drawn, were much too thick for the refined purposes of the astronomer, as they entirely obliterated the image of a star in the more powerful telescopes. To obviate this difficulty Felice Fontana of Florence (*Saggio del real gabinetto di fisica e di storia naturale*, 1755) first proposed the use of spider webs in micrometers,[1] but it was not till the attention of Troughton had been directed to the subject by Rittenhouse that the idea was carried into practice.[2] In 1813 Wollaston proposed fine platinum wires, prepared by surrounding a platinum wire with a cylinder of silver, and drawing out the cylinder with its platinum axis into a fine wire.[3] The surrounding silver was then dissolved by nitric acid, and a platinum wire of extreme fineness remained. But experience soon proved the superiority of the spider web; its perfection of shape, its lightness and elasticity, have led to its universal adoption.

Beyond the introduction of the spider line it is unnecessary to mention the various steps by which the Gascoigne micrometer assumed the modern forms now in use, or to describe in detail the suggestions of Hooke,[4] Wren, Smeaton, Cassini, Bradley, Maskelyne, Herschel, Arago, Pearson, Bessel, Struve, Dawes, &c., or the successive productions of the great artists Ramsden, Troughton, Fraunhofer, Ertel, Simms, Cooke, Grubb, Clarke and Repsold. It will be sufficient to describe those forms with which the most important work has been done, or which have survived the tests of time and experience.

Before astronomical telescopes were mounted parallactically, the measurement of position angles was seldom attempted. Indeed, in those days, the difficulties attached to such measures, and to the measurement of distances with the filar micrometer, were exceedingly great, and must have taxed to the utmost the skill and patience of the observer. For, on account of the diurnal motion, the direction of the axis of the telescope when pointed to a star is always changing, so that, to follow a star with an altazimuth mounting, the observer requires to move continuously the two handles which give slow motion in altitude and azimuth.

Sir William Herschel was the first astronomer who measured position angles; the instrument he employed is described in *Phil. Trans.* (1781), lxxi, 500. It was used by him in his earliest observations of double stars (1779–1783); but, even in his hands, the measurements were comparatively crude, because of the difficulties he had to encounter from the want of a parallactic mounting. In the case of close double stars he estimated the distance in terms of the disk of the components. For the measurement of wider stars he invented his lamp-micrometer, in which the components of a double star observed with the right eye were made to coincide with two lucid points placed 10 ft. from the left eye. The distance of the lucid points was the tangent of the magnified angles subtended by the stars to a radius of 10 ft. This angle, therefore, divided by the magnifying power of the telescope gives the real angular distance of the centres of a double star. With a power of 460 the scale was a quarter of an inch for every second.

The Modern Filar Micrometer.

When equatorial mountings for telescopes became more general, no filar micrometer was considered complete which was not fitted with a position circle.[5] The use of the spider line or filar micrometer became universal; the methods of illumination were improved; and micrometers with screws of previously unheard of fineness and accuracy were produced. These facilities, coupled with the wide and fascinating field of research opened up by Sir William Herschel's discovery of the binary character of double stars, gave an impulse to micrometric research which has continued unabated to the present time. A still further facility was given to the use of the filar micrometer by the introduction of clockwork, which caused the telescope automatically to follow the diurnal motion of a star, and left the observer's hands entirely at liberty.[6]

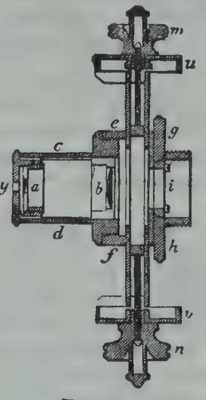

FIG. 1.

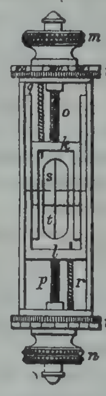

FIG. 2.

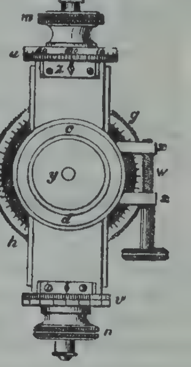

FIG. 3.

The micrometer represented in figs. 1, 2, 3 is due to Troughton. Fig. 1 is a horizontal section in the direction of the axis of the telescope. The eyepiece *ab* consists of two plano-convex lenses *a*, *b*, of nearly the same focal length, and with the two convex sides facing each other. They are placed at a distance apart less than the focal length of *a*, so that the wires of the micrometer, which must be distinctly seen, are beyond *b*. This is known as Ramsden's eyepiece, having been made originally by him. The eyepiece slides into the tube *cd*, which screws into the brass ring *ef*, through two openings in which the oblong frame, containing the micrometer slides, passes. These slides are shown in fig. 2, and consist of brass forks *k* and *l*, into which the ends of the screws *o* and *p* are rigidly fitted. The slides are accurately fitted so as to have no sensible lateral shake, but yet so as to move easily in the direction of the greatest length of the micrometer box. Motion is communicated to the forks by female screws tapped in the heads *m* and *n* acting on the screws *o* and *p* respectively. Two pins *q*, *r*, with spiral springs coiled round them, pass loosely through holes in the forks *k*, *l*, and keep the bearings of the heads *m* and *n* firmly pressed against the ends of the micrometer box. Thus the smallest rotation of either head communicates to the corresponding slide motion, which, if the screws are accurate, is proportional to the amount through which the head is turned. Each head is graduated into 100 equal parts on the drums *u* and *v*, so that, by estimation, the reading can easily be carried to $\frac{1}{1000}$th of a revolution. The total number of revolutions is read off by a scale attached to the side of the box, but not seen in the figure.

Two spider webs are stretched across the forks, one (*t*) being cemented in a fine groove cut in the inner fork *k*, the other (*s*) in a similar groove cut in the outer fork *l*. These grooves are simultaneously cut *in situ* by the maker, with the aid of an engine capable of ruling fine straight lines, so that the webs when accurately laid in the grooves are perfectly parallel. A wire *st* is stretched across the centre of the field, perpendicular to the parallel wires. Each movable web must pass the other without coming in contact with it or the fixed wire, and without rubbing on any part of the brass-work. Should either fault occur (technically called "fiddling") it is fatal to accurate measurement. One of the most essential points in a good micrometer is that all the webs shall be so nearly in the same plane as to be well in focus together under the highest powers used, and at the same time absolutely free from "fiddling." For measuring position angles a brass circle *gh* (fig. 3), fixed to the telescope by the screw *i*, has rack teeth on its circumference that receive the teeth of an endless screw *w*, which, being fixed by the arms *xx* to the oblong box *mn*, gives the latter a motion of rotation round the axis of the telescope; an index upon this box points out on the graduated circle *gh* the angular rotation of the instrument.

---

[1] In 1782 (*Phil. Trans.* lxxii. 163) Sir W. Herschel writes:—"I have in vain attempted to find lines sufficiently thin to extend them across the centres of the stars, so that their thickness might be neglected." It is a matter of regret that Fontana's suggestion was unknown to him.

[2] J. T. Quekett in his *Treatise on the Microscope* ascribes to Ramsden the practical introduction of the spider web in micrometers. The evidence appears to be in favour of Troughton.

[3] *Phil. Trans.* (1813), pp. 114–118.

[4] Dr Hooke made the important improvement on Gascoigne's micrometer of substituting parallel *hairs* for the parallel edges of its original construction (Hooke's *Posthumous Works*, p. 497).

[5] Herschel and South (*Phil. Trans.*, 1824, part iii. p. 10) claim that the micrometer by Troughton, fitted to their 5 ft. equatorial telescope, is the first position micrometer constructed capable of measuring position angles to 1′ of arc.

[6] So far as we can ascertain, the first telescope of large size driven by clockwork was the 9-in. equatorial made for Struve at Dorpat by Fraunhofer; it was completed in 1825. The original idea appears to be due to Claude Simeon Passemant (*Mem. Acad.*, Paris, 1746). In 1757 he presented a telescope to the king, so accurately driven by clockwork that it would follow a star all night long.

The English micrometer still retains the essential features of Troughton's original construction above described. The later English artists have somewhat changed the mode of communicating motion to the slides, by attaching the screws permanently to the micrometer head and tapping each micrometer screw into its slide. Instead of making the shoulder of the screw a flat bearing surface, they have given the screw a spherical bearing resting in a hollow cone (fig. 4) attached to the end of the box. The French artists still retain Troughton's form.

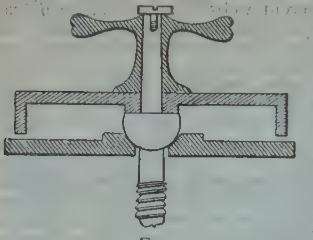

FIG. 4.

Fraunhofer's Filar Micrometer.—The micrometer represented in fig. 5 [1] is the original Merz micrometer of the Cape Observatory, made on Fraunhofer's model. S is the head of the micrometer screw proper, *s* that of the screw moving the slide to which the so-called "fixed web" is attached, *s'* that of a screw which moves the eyepiece E. C is the clamp and M the slow motion in position angle. L, L are tubes attached to a larger tube N; the latter fits loosely on a strong hollow cylinder which terminates in the screw V. By this screw the whole apparatus is attached to the telescope. The nozzles of small lamps are inserted in the tubes L, L, for illuminating the webs in a dark field; the light from these lamps is admitted through apertures in the strong hollow cylinder above mentioned (for illumination, see p. 385). In this micrometer the three slides moved by *S*, *s*, and *s'* are simple dovetails. The lowest of these slides reposes upon a foundation-plate *pp*, into one end of which the screw *s* is tapped. In the middle of this slide a stiffly fitting brass disk is inserted, to which a small turn-table motion may be communicated by an attached arm, acted on by two fine opposing screws accessible to the astronomer; and by their means the "fixed web" may be rendered strictly parallel with the movable one. Another web is fixed parallel to the axis of the screw, as nearly as possible in the same plane with it and passing through the axis of rotation of the micrometer. For the internal structural details of the micrometer the reader is referred to the article "Micrometer" in the 9th edition of the *Encyclopaedia Britannica.*

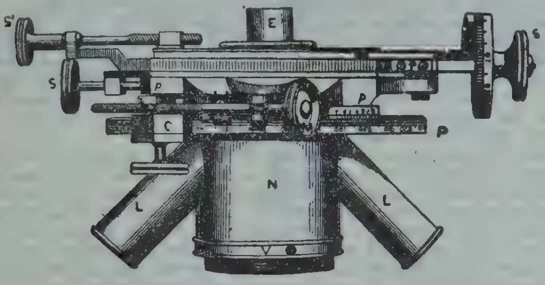

FIG. 5.

To use the instrument, it is well first to adjust the web moved by the screw S, so that its point of intersection with the web (commonly called the "position-web"), which is parallel to the axis of the screw, shall be nearly coincident with the axis of rotation of the micrometer box. For this purpose it is only necessary to direct the telescope to some distant object, bisect that object with the movable wire, and read the number of revolutions and parts of a revolution of the screw; now reverse the micrometer box 180° and repeat the observation; the mean of the two readings will be the point required. Now direct the telescope to a star near the equator and so that the star's image in its diurnal motion shall pass across the intersection of the two webs which mark the axis of rotation of the micrometer box. Then, as the diurnal motion causes the star-image to travel away from the axis of rotation, the micrometer box is rotated till the image of the star when at a considerable distance from the axis is bisected by the position-web. The micrometer is now clamped in position-angle by the clamp C, the star again brought back to the axis, and delicate adjustment given in position-angle by the slow-motion screw M, till the star-image remains bisected whilst it traverses the whole length of the position-web by the diurnal motion only. This determines the reading of the position-circle corresponding to position-angle 90° or 270°.[2]

The position-angles of double stars are reckoned from north through east, the brighter star being taken as origin. To observe the position-angle of a double star it is only necessary to turn the position-web so that it shall be parallel to the line joining the centres of the components of the double star. To test this parallelism the single web must be made to bisect the images of both components simultaneously, as in fig. 6, because it is evident that if the two components of the double star are not exactly equal in magnitude, there will be great tendency to systematic error if the web is placed on one side or other of the stars.

FIG. 6.

To avoid such error Dawes used double *wires*, not spider webs, placing the image of the star symmetrically between these wires, as in fig. 7, and believed that by the use of wires, much thicker than spider webs, the eye could estimate more accurately the symmetry of the star-images with respect to the wires. Other astronomers use the two distance-measuring webs, placed at a convenient distance apart, for position wires. This plan has the advantage of permitting easy adjustment of the webs to such a distance apart as may be found most suitable for the particular observation, but has the disadvantage that it does not permit the zero of the position-circle to be determined with the same accuracy; because, whilst by means of the screw *s'* (fig. 5) the eyepiece can be made to follow the star for a considerable distance along a position-web parallel to the screw, the bisection of the web by a star moving by the diurnal motion at right angles to the micrometer screw can only be followed for a limited distance, viz. the field of the eyepiece. But, as the angle between the position-web and the distance-webs is a constant, the remedy is to determine that angle (always very nearly a right angle) by any independent method and employ the distance-webs as position-webs in the way described, using the position-web only to determine the instantaneous index error of the position-circle.

FIG. 7.

To measure distances with the Fraunhofer micrometer, the position-circle is clamped at the true position-angle of the star, and the telescope is moved by its slow motions so that the component A of the star is bisected by the fixed wire; the other component B is then bisected by the web, which is moved by the graduated head S. Next the star B is bisected by the fixed web and A by the movable one. The difference between the two readings of S is then twice the distance between A and B.

The great improvement now introduced into all the best micrometers is to provide a screw *s*, which, not as in the Fraunhofer micrometer, moves only one of the wires, but which moves the whole micrometer box, *i.e.* moves both webs together with respect to the star's image in the direction of the axis of the screw. Thus the fixed wire can be set exactly on star A by the screw *s*, while star B is simultaneously bisected by the movable wire, or vice versa, without disturbing the reading for coincidence of the wires. No one, unless he has previously worked without such an arrangement, can fully appreciate the advantage of bringing up a star to bisection by moving a micrometer with a delicate screw-motion, instead of having to change the direction of the axis of a huge telescope for the same purpose. When it is further remembered that the earlier telescopes were not provided with the modern slow motions in right ascension and that the Struves, in their extensive labours among the double stars, used to complete their bisections of the fixed wire by a pressure of the finger on the side of the tube, one is puzzled whether more to wonder at such poor adaptation of means to ends or the patience and skill which, with such means, led to such results.[3] Dawes, who employed a micrometer of the English type (figs. 1, 2 and 3), used to bolt the head of one of the screws, and the instrument was provided with a slipping piece, giving motion to the micrometer by screws acting on two slides, one in right ascension, the other in declination, so that "either of the webs can be placed upon either component of a double star with ease and certainty" (*Mem. R.A.S.* xxxv. 19).

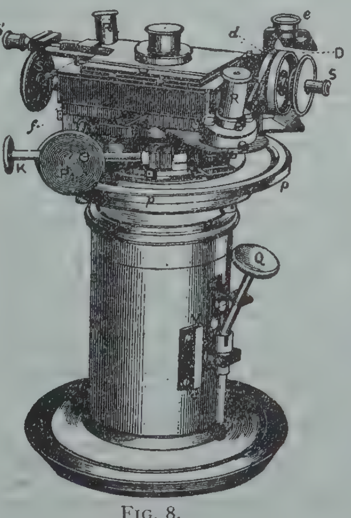

FIG. 8.

The micrometer shown in fig. 8 was made by Repsolds for the Cape Observatory. Fig. 9 represents the same micrometer with the upper side of the box removed. The letters in the description refer to both figures.

---

[1] When it is remembered that the measurements of the Struves, Dembowski, Secchi, the Bonds, Maclear and of most modern European astronomers have been made with Fraunhofer or Merz micrometers it is not too much to say that fig. 5 represents the instrument with which a half of the astronomical measurements of the 19th century were made.

[2] For the corrections applicable to measures of position-angle in different hour angles, on account of errors of the equatorial instrument and of refraction, see Chauvenet's *Practical and Spherical Astronomy*, ii. 392 and 450.

[3] Professor Watson used to say, "After all the most important part of a telescope is the man at the small end."

S is the head of the micrometer screw, s that of the screw by which the micrometer box is moved relative to the plate f (fig. 8), s' that of the screw which moves the eyepiece slide. K is the clamp in position angle, P the slow motion screw in position-angle; pp is the position circle, R, R its two readers. The latter are in fact little microscopes carrying a vernier etched on glass, in lieu of a filar micrometer. These verniers can be read to $1'$, and estimated to $0'\cdot 2$. D is the drum-head which gives the fraction of a revolution, d that which gives the whole number of revolutions, I is the index or pointer at which both drums are read. This index is shown in fig. 9, but only its mode of attachment (X, fig. 9) in fig. 8. The teeth of the pinion z, fig. 9, are cut on the axis of the micrometer screw. The drum d and its attached tooth wheel are ground to turn smoothly on the axis of the screw. The pinion z and the toothed wheel d are connected by an intermediate wheel and pinion Y; the numbers of teeth in the wheels and pinions are so proportioned that twenty-four revolutions of the micrometer screw produce one revolution of the drum and wheel d. The divisions of both drums are conveniently read, simultaneously, by the lens e; at night the lamp which illuminates the webs and the position-circle also illuminates the drum-heads (see on illumination p. 385). $aaaa$ is the web-frame (fig. 9), $\beta\gamma$ is a single rod consisting of two cylinders accurately fitting in the ends of the micrometer box, the larger cylinder being at β. There is a hole in the web-frame which smoothly fits the larger cylinder at β', and another which similarly fits the smaller cylinder at γ'. A spiral spring, coiled round the cylinder γ, resting one end on the shoulder formed by the difference of the diameters of the cylinders β and γ and the other on the inside of the web-frame, presses the latter continuously towards γ. Contact of the web-frame of the micrometer with the side of the box at γ would therefore take place, were it not for the micrometer screw. This screw fits neatly in the end of the box at ϵ, passes loosely through the web-frame at ϵ', is tapped into the frame at ζ', and its end rests on a flat hardened surface at ζ. Rotation of the web-frame about $\beta\gamma$ is prevented by the heads of the screws at m; the head of the screw on the lower side of the frame reposes on the plane $\nu\nu$, that on the upper side (fig. 9) touches lightly on the inner surface of the lid of the box. Such rotation can obviously be controlled within limits that need not be further considered. But freedom of rotation in the plane of the paper (fig. 9) is only prevented by good fitting of the holes β' γ'; and, since the weight of the slide is on one side of the screw, misfit here will have the effect of changing the reading for coincidence of the movable with the fixed web in reverse positions of the micrometer. With the Cape micrometer a systematic difference has been found in the coincidence point for head above and head below amounting to $0''\cdot 14$. This corresponds, in the Cape instrument, with an excess of the diameters of the holes over those of the cylinders of about $\frac{1}{15000}$th of an inch—a quantity so small as to imply good workmanship, though it involves a systematic error which is very much larger than the probable error of a single determination of the coincidence point. The obvious remedy is to make all measures on opposite sides of the fixed web before reversing in position-angle—a precaution, however, which no careful observer would neglect. In measuring differences of declination, where the stars are brought up by the diurnal motion, this precaution cannot be adopted, because it is necessary always to bisect the preceding star with the fixed web. But in $\Delta\delta$ measures index error can be eliminated by bisecting both stars with the same web (or different webs of known interval fixed on the same frame), and not employing the fixed web at all. The discordance in zero, when known to exist, is really of no consequence, because the observations can be so arranged as to eliminate it.

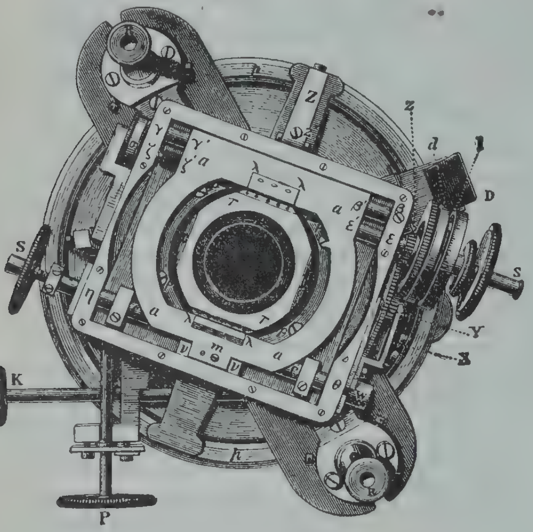

FIG. 9.

The box is mounted on a strong hollow steel cylinder CC (fig. 9) by holes η, θ in the ends of the box, which fit the cylinder closely and smoothly. The cylinder is rigidly fixed in the studs C, C, and these are attached to the foundation plate f. The cylinder contains towards η a sliding rod, and towards θ a compressed spiral spring. There is thus a thrust outwards of the spring upon the hollow cap W (attached outside the box), and a thrust of the rod upon the end of the screw s. The position of the box relative to the plate f, in the direction of measurement, depends therefore on the distance between the end of the screw s and the fixed stud C. A screwing in of s thus causes the box to move to the left, and vice versa. Rotation of the box round CC is prevented by downward pressure of the spring Z on a projection attached to the side of the box. The amount of this pressure is regulated by the screw z'.

The short screw whose divided milled head is σ shifts the zero of the micrometer by pushing, without turning, the short sliding rod whose flat end forms the *point d'appui* of the micrometer screw at ζ. The pitch of the screw σ is the same as that of the measuring screw (50 threads to the inch), and its motion can be limited by a stop to half a revolution.

The five fixed webs are attached to the table $\tau\tau$, which is secured to the bottom of the box by the screws ρ. The three movable webs are attached to the projections $\lambda\lambda$ on the frame aa. The plane surfaces $\tau\tau$ and $\lambda\lambda$ are composed of a bronze of very close texture, which appears capable of receiving a finish having almost the truth and polish of an optical surface. It seems also to take a very clean V cut, as the webs can be laid in their furrows with an astonishing ease and precision. These furrows have apparently been cut *in situ* with a very accurate engine; for not the slightest departure from parallelism can be detected in any of the movable webs relative to the fixed webs. Extraordinary care has evidently been bestowed in adjusting the parallelism and distance of the planes τ and λ, so that the movable wires shall almost, but not quite, touch the surface τ. The varnish to fix the webs is applied, not on the surface τ as is usual, but on a bevel for the purpose,[1] the position of the webs depending on their tension to keep them in their furrows. The result is that no trace of "fiddling" exists, and the movable and fixed webs come sharply together in focus with the highest powers. Under such powers the webs can be brought into apparent contact with such precision and delicacy that the uncertainty of measurement seems to lie as much in the estimation of the fraction of the division of the head as in the accuracy of the contact. It is a convenient feature in Repsolds' micrometer that the webs are very near the inner surface of the top of the box, so that the eye is not brought inconveniently close to the plate when high powers are used.

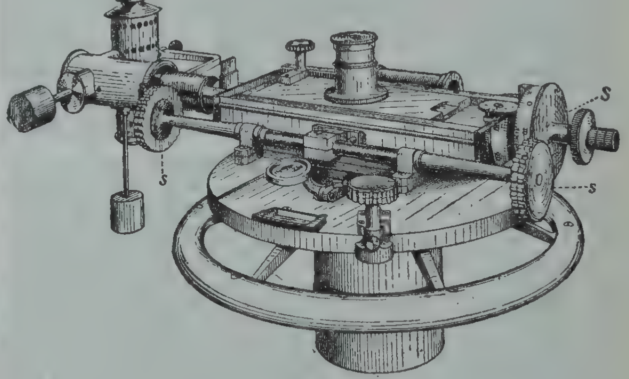

FIG. 10.

Another excellent micrometer, originally based on a model by Clark of Cambridge, Massachusetts, has been largely used by Burnham and others in America. The form, as constructed by Warner and Swasey for the 40-in. Yerkes telescope, is shown in figs. 10 and 11. The micrometer box, and of course with it the whole system of spider webs, is moved by the screw s, whilst the measuring web is independently moved by the screw S. The other parts of the instrument will be readily understood from the figure without further explanation. The method of counting the total number of revolutions gives more friction and is less convenient than Repsolds', and no provision seems to be made for illuminating the micrometer head in the practical and convenient plan adopted by Repsolds.

Repsolds' more recent form of the spider-line micrometer (since

---

[1] The marks of varnish so applied will be seen in fig. 9.

1893) for large telescopes is shown in fig. 12. Quick motion in position-angle for rough setting or for the measurement of close double stars is given by the large ring R. The micrometer is clamped in position-angle by the screw K and slow motion in position-angle is given by the screw *p*. The small drum-head T opposite the micrometer head S turns a screw which acts upon a short cylinder that cannot turn but can move only in the direction of the axis of the micrometer screw. The end-plane of this cylinder receives the pressure of the micrometer screw, so that by turning the small drum-head the coincidence-reading of the movable web with the fixed web can be changed, and thus any given angle can be measured with different parts of the micrometer screw in order to eliminate the effects of periodic error of the screw. The electric lamp *a* gives illumination of the webs in a dark field, nearly in the manner described for the Cape transit circle micrometer; the intensity of illumination is regulated by a carbon-resistance controlled by the screw *b*. The lamp *c* illuminates the drum-head and also, by reflection, the portions of the position-circle which come under the microscopes *d* and *e*. The head *f* is a switch which enables the observer to illuminate lamp *a* or *c* at pleasure. These lamps, although shown in the figure, are in reality covered so as not to shine upon the observer's eye. The illumination of the field is given by a lamp near the object glass, controlled by a switch near the micrometer.

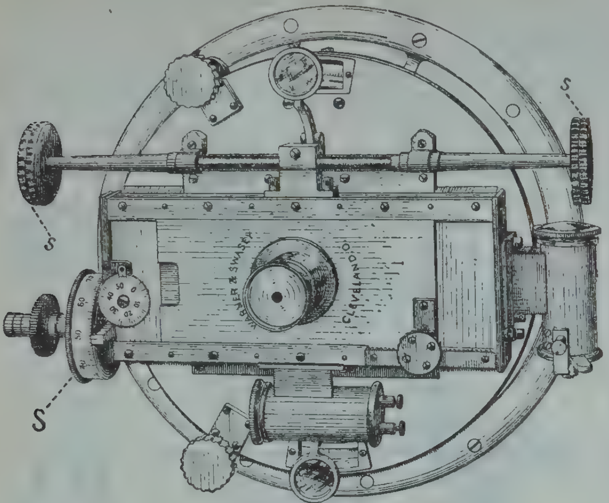

FIG. 11.

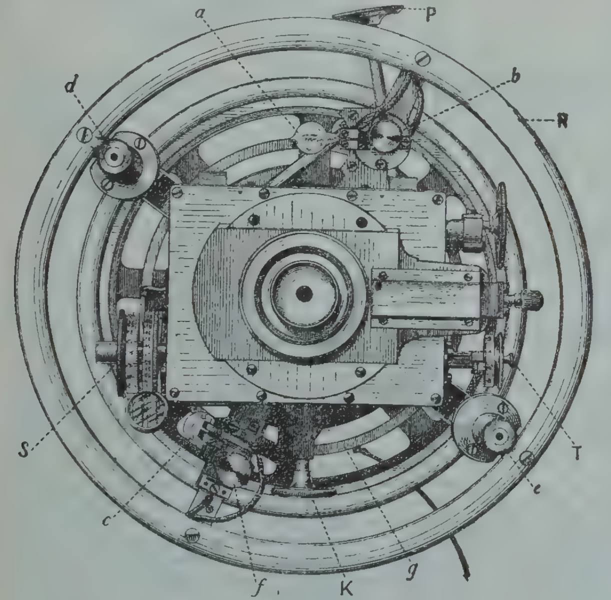

FIG. 12.

Repsolds in more recent micrometers under construction give a second motion to the eyepiece at right angles to the axis of the micrometer screw; this enables the observer to determine the zero of position-angle for his movable webs with the same accuracy as he formerly could only do for the so-called position-angle webs. Repsolds also provide two insulated sliding contact rings instead of the single ring *g*, so that the electric current for illuminating the lamps does not pass through the instrument itself but may come to the micrometer from the storage battery through two insulated leads. The same firm is also constructing a micrometer in which the readings of the head are printed on a band of paper instead of being read off at the time of observation.

Instruments have been invented by Alvan Clark and Sir Howard Grubb for measuring with the spider-line micrometer angles which are larger than the field of view of the eyepiece. In both cases two eyepieces are employed, one to view each separate web. One drawback to this form of instrument is that the two webs cannot be viewed simultaneously, and therefore the observer must rely on the steadiness of rate of the clockwork and uniformity in the conditions of refraction whilst the eye is moved from one eyepiece to the other.

Clark's micrometer was exhibited at the June meeting of the Royal Astronomical Society in 1859 (*Monthly Notices, R.A.S.*, vol. xix.). Grubb's duplex micrometer is described in the 9th edition of the *Encyclopaedia Britannica*. Some examples of use of the latter are given by Professor Pritchard (*Mem. R.A.S.* xlvii. 4–12), who estimates the accuracy attainable with the duplex micrometer as equal to that of the heliometer; but as few measures of permanent value have been made with the instrument, and those made exhibit an accuracy far inferior to that of the heliometer, it is unnecessary to describe the instrument here in greater detail.

The Reading Micrometer-Microscope.—Micrometers used for subdividing the spaces on graduated circles and scales have, in general, only a single pair of cross-webs or parallel webs moved by a single screw. The normal form of the apparatus is shown in figs. 13 and 14. C is the objective, D the micrometer box, E the graduated head of the screw, G the milled head by which the screw *cc* is turned, A an eyepiece sliding in a tube B, *aa* (fig. 14) the slide, and *b*, *b* the spiral springs. The focal length of the objective and the distance between the optical centre of the lens and the webs are so arranged that images of the divisions are formed in the plane of the webs, and the pitch of the screw is such that one division of the scale corresponds with some whole number of revolutions of the screw.

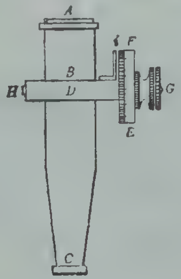

FIG. 13.

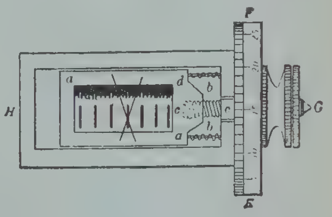

FIG. 14.

There is what is technically called a "comb" inserted in the micrometer box at *d* (fig. 14)—its upper surface being nearly in the plane of the wires. This comb does not move with reference to the box, and serves to indicate the whole revolution of which a fraction is read on the head. In fig. 14 a division is represented bisected by cross webs, and five revolutions of the screw correspond with one division of the scale. In all modern reading micrometers the cross webs of fig. 14 are replaced by parallel webs embracing the division (fig. 15). The means for changing the length of the tube and the distance of C from the scale are omitted in the figure. These appliances are required if the "run" has to be accurately adjusted. By "run" is meant the difference between the intended whole number of screw-revolutions and the actual measures of the space between two adjacent divisions of the scale in turns of the screw divided by the number of intended revolutions. In delicate researches two divisions of the scale should always be read, not merely for increased accuracy but to obtain the corrections for "run" from the observations themselves.

FIG. 15.

Repsolds employ for the micrometers of their reading microscopes the form of construction shown in fig. 9, omitting, of course, the motion of the whole micrometer box given by the screw *s* for those cases in which the axis of the micrometer is supposed to remain constant in position, as, for example, in the case of the reading microscopes of transit circles (see TRANSIT CIRCLE).

But when the relative positions of two adjacent objects or scale-divisions have to be determined (as, for example, in the case of heliometer scales), much time is saved by retaining the motion of the micrometer box. One double web, fixed in the box, is pointed symmetrically, as in fig. 15, on one of the scales, by moving the whole micrometer box by means of the screw *s*; the pair of webs, moved by the screw S, is then pointed upon an adjacent division on the other scale. If the reading for coincidence of the movable with the fixed webs is known, we then obtain from the single reading of S the difference from coincidence of the divisions of the two scales.

It is generally possible so to arrange the method of observation as to eliminate the effect of an error in "the reading for coincidence of the webs" from the results. This excellent time-saving contrivance has also been used in Gill's apparatus for measuring astrographic plates (see below).

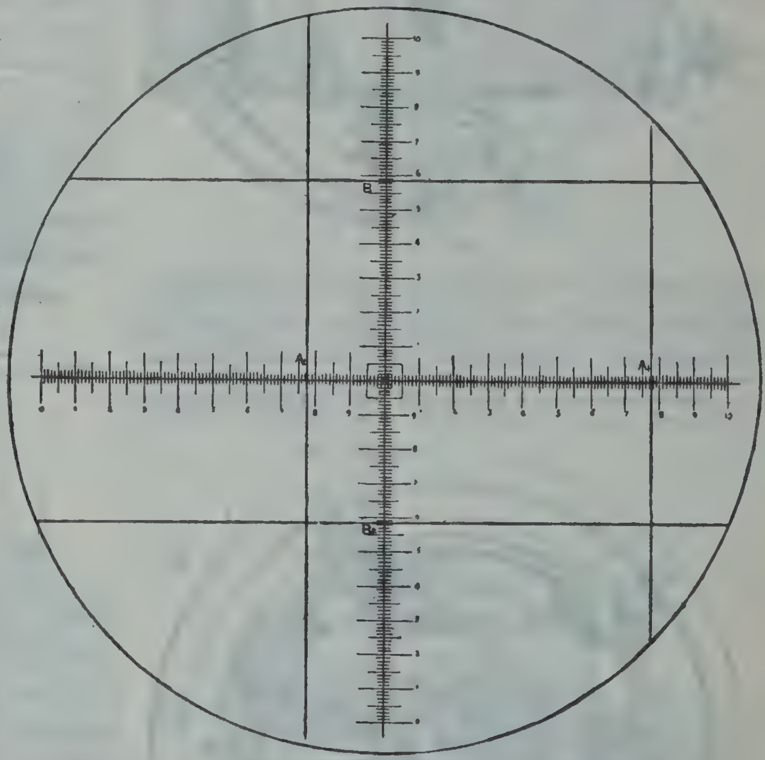
Ghost Micrometer.—C. E. Burton and Sir Howard Grubb (*Monthly Notices*, xli. 59), after calling attention to J. von Lamont's paper (*Jahrbuch der K. S. b. München*, p. 187) and K. L. von Littrow's paper (*Proc. of Vienna Acad. of Sciences*, xx. 253) on a like subject, proceed to describe a most ingenious form of "Ghost Micrometer," in which the *image* of a fine line or lines ruled in (or rather cut through) a silver film deposited on glass is formed at the common focus of an object-glass and eyepiece of a telescope. A faint light being thrown on the outside of the silvered plate, there appear bright lines in the field of view. We have not had an opportunity of testing this, nor Grubb's more recent models; but, should it be found possible to produce such images satisfactorily, without distortion and with an apparatus convenient and rigid in form, such micrometers may possibly supersede the filar micrometer. Their absolute freedom from diffraction, the perfect control of the illumination and thickness of the lines, and the accuracy with which it will be possible to construct scales for zone observations will be important features of the new method.

The Astrographic Micrometer or Measuring Machine.—The application of photography to exact astronomy has created the necessity for new forms of apparatus to measure the relative positions of stellar and planetary images on photographic plates, and the relative positions of lines in photographic spectra.

Especially important has been the problem of measuring the "catalogue plates" of the international *Carte du ciel*—a work that implies the determination of the positions of some millions of stars—that is to say, of all stars to the 11th or 12th magnitude. The problem has been how to accomplish this work with the minimum of labour consistent with the desired accuracy. The adoption of a réseau photographed upon the plate has greatly facilitated the procedure. A plate of parallel-surfaced glass has a film of silver deposited upon it. On this film is ruled a system of lines 5 mm. apart, and another similar system of lines at right angles to the first, thus dividing the silvered surface of the plate into squares 5 mm. on the side. The cutter employed to rule these lines removes the silver in fine lines from the surface of the glass. Thus, if a photographic plate, before it is exposed in the telescope, is placed with its sensitive surface nearly in contact with the silvered surface of this réseau, and if parallel light, normal to the surface of the plate, is allowed to fall on the silvered film through the glass on which the film has been deposited, that light will pass through the fine lines in the silver film where the silver has been removed by the cutter, but will otherwise be intercepted by the silver film. Thus a latent image of the "réseau-lines" will be formed on the sensitive plate, and, when the latter has been exposed to the sky in the telescope, we obtain, on development, a negative of the images both of the stars and of the réseau-lines. If the errors of the rectangular co-ordinates of these lines are known, the problem of determining the co-ordinates of any star-image on the plate becomes reduced to the comparatively simple one of interpolating the co-ordinates of the star relative to the sides of the 5 mm. square within which that image is included. This interpolation can, of course, be accomplished with the aid of a micrometer-microscope whose optical axis is normal to the plate, provided that the plate is mounted on slides which enable the observer to bring the réseau-squares successively under the microscope.

This system has an additional advantage beyond its convenience, viz. that if any distortion of the film takes place during development the same distortion will be communicated both to the star-images and to the réseau-lines, and consequently its effect will be eliminated from the resulting star co-ordinates, except in so far as the distortion within the 5 mm. square is of an irregular character; this exception is hardly worth consideration. An originally unanticipated difficulty has arisen from the fact that the réseau-lines have not been ruled on plates of optical glass with optical surfaces, and that, in consequence of irregular refraction in the glass plate, the rays do not always pass through the silver film-lines in a direction strictly normal to the silvered surface; therefore, if the sensitive surface of the photographic plate is not in contact with the silver film of the réseau, the undeveloped photographic copy of the réseau may in such a case not be an exact reproduction of the silvered réseau. It is practically impossible to work with the sensitive film in contact with the réseau-film, not only because dust particles and contact would injure the silver film, but also because the plate-glass used for the photographic plates is seldom a perfect plane. The discrepancies produced in this way are, however, very small, if care is taken to minimize the distance between the silver film and the photographic plate and to select a reasonably good piece of glass for the réseau. For very refined work, however, the irregularities in the reproduction of the réseau may be studied by comparing the measures of the original réseau with the mean of corresponding measures of a number of photographed copies of it.

At Greenwich, Oxford and several other observatories, instead of measuring the distances of the star's image from the opposite sides of the 5 mm. réseau-square by means of a spider-line micrometer, a glass scale, on the plan shown in fig. 16, is employed in the common focus of the objective and the eyepiece. The image of the star is set upon the intersections of the lines of the central cross, and the positions of the réseau-lines are read off by estimation to $\frac{1}{10}$ of a division on the glass scale. As each division corresponds to 3 sec. of arc, the nearest estimate corresponds with a nominal accuracy of ± 0·3″. This involves a loss of accuracy because, with a spider-line micrometer, the accidental error of pointing is of the order of ± 0·1″ of arc.



Greenwich Astrographic Catalogue, vol. i., by permission of the Controller of H.M. Stationery office.

Fig. 16.—Diagram of the diaphragm in eyepieces of the micrometer used for measuring the plates of the Astrographic Catalogue.

In the measuring machines in general use the field of view, as in the case of the glass-scale micrometer, is sufficiently large to include the image of the 5 mm. square. The microscope or viewing telescope is fitted with a spider-line micrometer having two screws at right angles to each other, by means of which readings can be made first on one réseau-line, then on the star, and finally on the opposite réseau-line in both co-ordinates. This form of micrometer is of course capable of giving results of high precision, but the drawback is that the process involves a minimum of six pointings and the entering of six screw-head readings in order to measure the two co-ordinates of the star.

Gill's Measuring Machine.—Sir David Gill (*Monthly Notices, R.A.S.* lix. 61) devised a measuring machine which combines the rapidity of the glass-scale micrometer with the accuracy of the spider-line micrometer and simplifies the reductions of the observations at the same time. The essential conditions of the instrument are:—

1. The object glass of the micrometer-microscope is placed midway between the plane of the photographic plate and the plane of the micrometer webs.

2. The micrometer is provided with a "fixed square" 5 mm. × 5 mm., the sides of this square being parallel spider webs 4″ of arc apart; the size of the square is reckoned from centre to centre of these double webs.

3. The two micrometer screws (X and Y, fig. 17), which actuate the movable slides, have heads divided into 100 parts, one revolution =0·5 mm.; so that ten revolutions are ≑ 5 mm., or = the interval between two adjacent réseau-lines, or = the interval between the sides of the "fixed square."

4. Two other screws, *o*, *p*, the heads of which are not graduated, give motions to the whole micrometer box through ≑ 1 mm. in directions parallel to the axes of the two micrometer screws.

5. Each of the two micrometer screws X and Y moves a system of six parallel webs, placed 4″ of arc apart from each other. These webs serve not only for pointing on stars to determine their co-ordinates (in manner afterwards described), but also for estimating the diameters of the star-images in terms of these 4″ intervals.

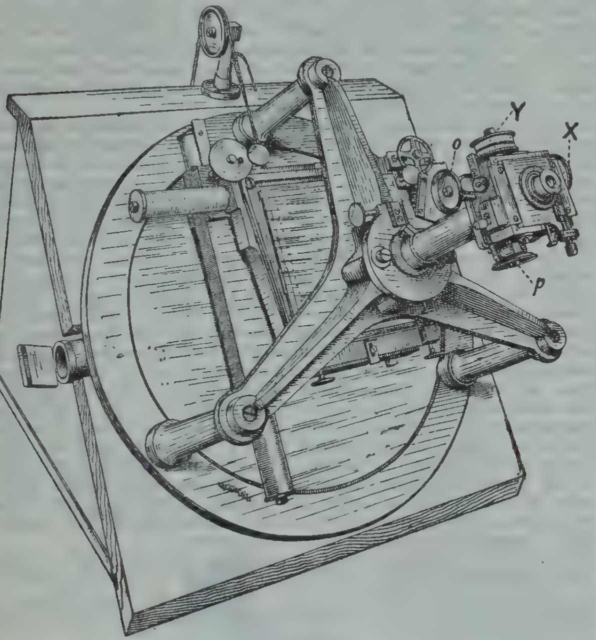


FIG. 17.

6. All the essential parts of the micrometer, including the slides, micrometer box, tube, &c., are of steel or cast-iron, so that changes of temperature do not affect the adjustments.

The necessary adjustments are the following:—

1. The webs of each set of movable webs shall, *inter se*, be strictly parallel, and the two sets shall be strictly at right angles to each other.

2. The double webs composing the sides of the fixed square shall be strictly parallel, and shall form a true square of exactly ten revolutions of the screw on the side.

3. The two micrometer screws shall be without sensible periodic or other error, and exactly alike in pitch.

4. The micrometer readings for coincidence of the movable webs with the webs of the fixed square shall be exactly $0{\cdot}000^{\mathrm{R}}$ and $10{\cdot}000^{\mathrm{R}}$.

5. The image of a normal réseau-square, as viewed in the microscope, shall exactly coincide with the square formed by the fixed webs—that is to say, the image of the sides of a normal réseau-square shall measure exactly 10 screw-revolutions.

Assuming that these conditions can be rigidly realized, we have the following very simple *modus operandi*:—

1. By means of the quick rack motions A and B move the plate so as to bring the réseau-square into the centre of the field of the micrometer; then, by means of the screw heads *o*, *p*, perfect the coincidence of the "fixed square" of webs, with the image of the réseau-square.

2. By means of one of the micrometer screws X place the star's image in the middle of the six parallel webs which are moved by X.

3. Similarly, place the star's image in the middle of the webs moved by Y.

4. Estimate the diameter of the star's image in terms of the 4″ intervals of the movable webs.

By employing both hands, operation (1) can be made as quickly as a single pointing with the ordinary spider-line micrometer, and operations (2) and (3) can be similarly performed in the time required for a single pointing. The reading (2) is then the required co-ordinate in x and that of (3) is the required co-ordinate in y; or, if the plate is reversed, 180°, these readings have to be subtracted from $10{\cdot}000^{\mathrm{R}}$.

A general idea of the construction of the machine can be gathered from fig. 17 above, but the reader will find a detailed account of it, and of the manner in which the requisite adjustments are made, in the paper already quoted.

The apparatus has been used with complete success at the Royal Observatory, Cape of Good Hope, and at Melbourne, Sydney and Córdoba.

Effects of Wear on the Micrometer Screws.—The accuracy of this apparatus has been frequently criticized on the ground that errors are produced in the screws by the effect of wear. One reply to this is that it is not difficult to determine from time to time the errors of the screws and to apply the necessary corrections to the observations. But a little consideration will show that when the plate is reversed 180° the effects of errors of the screws produced by wear are practically eliminated.

In discussing the effect of wear upon a screw, it will be convenient to imagine the thread unrolled and forming a wedge, of which we can represent the unworn bearing-side by a straight line AB (fig. 18), on which rubs the block CD, which represents the female screw or bush, and moves between the points E and F, sometimes towards E, sometimes towards F, but having as often to measure short distances as long distances from the middle point of this range, and these as often towards E as towards F. Now, if CD is pressed by its weight or by a spring on the surface AB, the effect of wear will be to produce a symmetrical grinding away of both surfaces, which may be represented thus, fig. 19. That is to say, the screw-errors will be identical for revolution n and for $10-n$, and thus will disappear in their effect in the mean of observations made in reversed positions of the plate. At the Cape of Good Hope, after more than 200,000 pointings had been made, the screw-errors were redetermined; the results proved the truth of the above conclusions, viz. the absolute freedom of the derived co-ordinates from the effects of wear of the screws in the mean of measures made in reversed positions of the plate.

FIG. 18.

FIG. 19.

Hinks's Measuring Machine.—A very refined modification of the Cape machine is described by A. Hinks (*Monthly Notices, R.A.S.*, vol. 61, p. 444), and the instrument contains many elegant mechanical and optical details due to Horace Darwin and Messrs Zeiss respectively.

Its fundamental principle is that, by a combination of glass scales with a micrometer screw, "the chief part of the distance to be measured is read off on the scale; the fractional part of the scale-space is not estimated but measured by the screw." Hinks claims that thus never more than one- or two-tenths of a revolution of the screw need be used in making the measure, and little time is lost in running the screw backwards and forwards. All this is true, but three readings instead of one for each pointing, much more figure-work in computation (especially if corrections have to be applied to the scale readings to reduce them to exact normal screw readings), are factors which involve a far greater expenditure of time than making a few additional turns of a screw in the process of measurement. Hinks's further claim that, in consequence of the small motion of the screw, less error is produced in the screw by wear is not true; for, although large movements of the screw produce a large amount of wear, that wear is spread over longer parts of the screw but remains the same for any particular part of the screw; the resulting errors are exaggerated towards the extremity of the range of screw employed (see *Monthly Notices, R.A.S.*, vol. 45, p. 83), and are therefore more likely to produce errors which are not eliminated on reversal of the plate in cases where the screw range is not strictly limited, and the wear therefore not strictly symmetrical.

The excellent manner in which the scales and micrometers are mounted, the employment of a compound microscope for viewing the scales, with its ingeniously arranged and admirably efficient reversing prism, and the perfection of its slow motions for focusing and reading, combine to render this a most accurate and convenient instrument for very refined measures, although too slow for work in which the measures must depend on single pointings in each of two reversed positions of the plate, and where speed of working is essential.

Apparatus for Measuring Star-Spectra, &c.—These machines may be divided into three classes, viz. A, in which the motion of the slide which carries the photographic plate is measured entirely by a screw; B, in which that motion is measured by combination of a scale and screw; and C, in which the photographic plate is fixed and the measuring microscope is moved.

The chief drawback to type A is that the errors of the screw are liable to change by wear, otherwise the apparatus, as made and used at Potsdam, is, on the whole, a convenient and accurate one. In determining the errors of the screw of the Potsdam form of machine it is necessary to have regard to the fact that the screw is placed at one side of the slide, as in fig. 20.

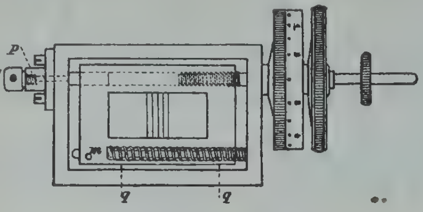

FIG. 20.

The result is that, if the screw is bent—if, for example, the end of the frame next the screw-head is raised and that next the end *p* is lowered in the diagram—a twist will be given to the web-frame, and the centre of the web will be moved nearer to the micrometer-drum than it should be, whilst the reverse effect will follow when the head has been turned 180°. This would, of course, create a periodic error, which would be determinable for the motion of any particular point (say the middle) of the web, but which would be smaller for a point near the axis of the screw and greater for a point farther from that axis. In the Potsdam form of this apparatus the micrometer is, for convenience, provided with a motion at right angles to the axis of the screw, and it has been found at the Cape Observatory that the periodic errors in this apparatus do vary very sensibly according as the microscope is directed to a point more or less distant from the measuring screw. Since the discovery of this fact all measurements have been made in that fixed position of the microscope with respect to the axis of the screw for which the errors of the screw have been determined.

In the apparatus of type B as made by Zeiss there are two microscopes attached to a base-plate, one of which views the spectrum-plate (or other object) to be measured, while the other views a scale that moves with the slide on which the spectrum-plate is mounted. In this way the scale can be viewed by a microscope of much higher magnifying power than can be employed for the photographed spectrum. Indeed, if the scale were subdivided to $\frac{1}{10}$ mm. the power employed might only be limited by the sharpness of the division-lines. But for refined work this would imply the investigation of too many divisions of the scale; it is therefore more usual to divide the scale into single millimetres or half-millimetres and to provide a micrometer which subdivides the millimetre into 1000 or, by estimation, into 10,000 parts. For very accurate work it is desirable that the base-plate, the slide and the scale should be of nickel steel, having the same thermal coefficient of expansion as glass.

The forms of measuring machines of type C, often seen in physical laboratories, should be at once rejected for refined measurements, because it is impossible to construct slides of such perfection that the axis of the microscope will remain absolutely normal to the surface of the plate (assumed to be a plane) throughout the range of measurement. Even if the slide itself is mechanically perfect, the irregularity in the thickness of the lubricating oil between the bearing surfaces of the slide is apt to produce a variable error.

Bakhuyzen (*Bulletin de Com. perm. congres. astrog*, i. 164) described a measuring-machine by Repsolds, in which the micrometer-microscope tilts in the bearings of the chariot on which it moves, so that it can view either a graduated scale or the photographic plate. We have, in fact, in this instrument a combination of types B and C. Even in this apparatus if the slide on which the chariot moves is not perfect (and no slide is perfect), the azimuth of the axis of the microscope is liable to change in the course of movement of the slide, and thus equal spaces on the scale will not be represented by equal spaces on the plate under measurement. The remedy proposed by Repsold for this proved fault is to cause the whole slide to tilt instead of the microscope only; this should prove a complete remedy.

The Travelling Wire Micrometer.—An important modern application of the micrometer, which is not dealt with in the article TRANSIT CIRCLE, is that which is now called "the travelling wire micrometer."

In the *Astronomische Nachrichten*, No. 2940, Dr Repsold proposed a method of meridian observing which consists in causing a web to follow the image of a star in transit by motions communicated by the observer's hands alone, whilst electrical contacts on the drum of the micrometer screw register on the chronograph the instants corresponding to known intervals from the line of collimation. The purpose of his paper was to show that if the axis, by which the observer imparts motion to the slide on which the travelling web is mounted, is provided with two disks at its extremities, so that the observer can use the thumb and finger of *both* hands in rotating it, there is no difficulty, after a little practice, in keeping the web constantly bisecting the star in transit, and that with a little practice the mean of the absolute errors in following the star becomes nearly zero.

In the *Astron. Nach.*, No. 3377, Repsold gives a detailed description of two forms of eye-ends of transit circles, fitted with means of observing in this manner, to which he gives the name of "the impersonal micrometer." This method of observation was very successfully employed, under Seeliger at Munich, in an extensive series of meridian observations, and, under the auspices of the Geodetic Institute at Potsdam, in telegraphic longitude operations. Still more recently the method has been largely employed at the Cape of Good Hope and elsewhere.

Under the date March 1901 Dr H. Struve published an account of the application of clockwork as an aid in Repsold's method; and, later, Dr Cohn published a more elaborate paper on the same subject in the *Astron. Nach.*, 3767. The method consisted in having motion transmitted to the micrometer screw from an axis on which is mounted a disk that presses with friction-contact upon a cone that revolves uniformly by clockwork. The velocity of rotation of the micrometer-screw could therefore be varied for stars of different declination by varying the distance from the apex at which the revolving disk presses upon the revolving cone. In the Königsberg transit instrument used by Struve and Cohn, the clockwork was attached to the eye-end of the instrument—a condition which is obviously undesirable both from the necessarily unsymmetrical position of the clockwork with respect to the optical axis, and from the impossibility of securing the uniform going of the clock in different positions of the instrument. In more recent instruments at the observatories of the Cape of Good Hope and Paris the motion is transmitted from a separately mounted cone and clock by a light rod passing through a perforation in the pivot of the transit instrument and thence through bevel-wheels in the cube of the axis to a second rod leading to the eyepiece. This rod turns a worm-screw which acts on a worm-wheel fitted "spring tight" upon the axis of the micrometer-screw.

It should be mentioned that an essential feature of the travelling wire micrometer is that the eyepiece as well as the wire shall be moved by the micrometer-screw. Thus, if the star's image is kept in bisection by the wire, both star and wire will appear at rest in the field of view.

The distinction between the old and new method of observation may thus, in one sense, be described as the difference between shooting at a moving object and in shooting at one at rest. In the case of the original Repsold plan without clockwork the description is not quite exact, because both the process of following the object and correcting the aim are simultaneously performed; whilst, if the clockwork runs uniformly and the friction-disk is set to the proper distance from the apex of the cone, the star will appear almost perfectly at rest, and the observer has only to apply delicate corrections by differential gear—a condition which is exactly analogous to that of training a modern gun-sight upon a fixed object. It is impossible in this article to give a detailed description of the apparatus, but the reader is referred to *Astron. Nach.*, 3377, for an illustrated account of the original Repsolds instrument and to the *History and Description of the Cape Observatory* for a complete description of the most modern form of its application to the Cape transit circle, with and without clockwork.

The Hartmann Spectrocomparator.—For accurate measurement of the displacements of lines of stellar spectra which are produced by the relative motion of star and observer in the line of sight, a very beautiful instrument has been devised by Dr J. Hartmann of Potsdam, and is described by him in the *Publicationen des astrophysikalischen Observatoriums zu Potsdam*, Bd. 18, Stück 53 (1906). An English translation of this paper is given in the *Astrophysical Journal*, xxiv. 285–302. The method originally used by Huggins, who first conceived and proved the possibility of measuring stellar velocities in the line of sight, was to measure with a filar micrometer the displacement of some well-known line in a stellar spectrum relative to the corresponding line of a terrestrial spectrum. Vogel of Potsdam introduced the method of photographing stellar and terrestrial spectra on the same plate, and in this way obtained an immense advance in the ease and precision of observation. Vogel and his successors employed one or other form of measuring machine, provided with a microscope having single or close parallel webs which could be successively pointed on the photographed lines of the star spectrum and the lines of the terrestrial spectrum. To derive the stellar velocity in the line of sight relative to the observer it was then necessary to assume that the normal wave-lengths of the stellar and terrestrial spectra are accurately known. But in the complex spectra of stars of the solar type this is by no means the case; for, as Dr Hartmann remarks, "in the first place the lines in these spectra are so numerous that their complete measurement and reduction would require many days, and in the second place a rigorous reduction of such material has hitherto not been at all possible because the wave-lengths of the lines are not known with sufficient accuracy. On this account, observers have until now limited themselves to a partial treatment of such spectra, measuring only a small number of lines, whereby the major part of the rich material present in the plate remains unutilized." But the spectroscopes that can be employed for stellar spectrographs are not sufficiently powerful to separate fully lines which are very closely adjacent, and therefore a line, assumed to be of a known wave-length, may be *apparently* displaced by the near neighbourhood of an unknown line. Hartmann overcame these and many other difficulties by directly superposing the image of the spectrogram of a star, having iron comparison lines, upon the image of a spectrogram of the sun taken also with iron comparison lines.

The apparatus for this purpose is shown in fig. 21, its principle of construction is shown in figs. 22 and 23. The solar spectrograph is attached by clamps to the plate A_1, the stellar spectrograph to the plate A_2. The plate A_1 is mounted on the dove-tailed slide B_1, upon the metallic stage T, and can be moved to right or left relative to T by the micrometer-screw S; whilst the plate A_2 is mounted on the dove-tailed slide B_2 and can be moved at right angles to its greatest length by the screw G. The micrometer-screw S has a pitch of 0·5 mm., its head is divided into 100 parts. Two spiral springs underneath press the plate B_1 with its agate end-bearing against the rounded end of the screw S. The whole number of revolutions of the screw is read by the scale X (fig. 23). The whole stage T, carrying both spectrograms, can be moved from right to left on the steel cylinder Z, by turning the head K, on the axis of which is a pinion that gears into a toothed rack attached to the lower side of the cylinder Z. A scale N on the cylinder Z serves for setting the slide to any required position. The preliminary conditions of measurement are:—

1. The centre of both spectrographs shall be parallel to the axis of the cylinder Z.

2. The distance between the centres of the two spectrographs shall be equal to the distance between the optical axes of the two viewing microscopes.

3. The scales of the images formed in the focus of the eyepiece common to both microscopes shall be identical.

To fulfil condition (1) the plates A_1 and A_2 are mounted in circular slides, whose centres are E_1 and E_2 respectively, so that by means of the screws D_1, D_2, with their corresponding opposing springs F_1 and F_2, the operation can be very easily accomplished. To fulfil condition (2) the two microscopes whose object glasses are O_1 and O_2 (fig. 22) are attached to the plate L, their optical axes being normal to the stage T. The screw Q serves to adjust the axis of O_1 to coincidence with the centre of the lines of the solar spectrograph, and the screw G then serves to move the slide B_2 till the optical axis of O_2 is coincident with the centre of the lines of the stellar spectrograph. Suppose now the solar spectrogram to be viewed in the focus of O_1, and the converging rays to be reflected by the prisms P_1 and P_3, till an image is formed in the focus of the eyepiece at the point where the axis of the eyepiece intersects

FIG. 21.

the upper face of the prism P_3. Then if the prism P_4 is cemented to P_3, a sharp image of such lines of the solar spectrograph as are visible in the field of view will be seen in the eyepiece. If the stellar spectrograph is viewed in the focus of O_2 and the converging rays are reflected by the prism P_2 to P_4, no image would be seen in the eyepiece, for the rays would pass out directly through the parallel glass plate which is formed by the cementing together of the prisms P_3 and P_4. But if the cemented face of P_4 is silvered, then the lines of the stellar spectrogram would be seen in focus of the eyepiece and the image of the solar spectrograph would be obliterated. Therefore, if one-half of the cemented face of P_4 is silvered, it becomes possible to view, side by side, one-half of the image of the solar spectrograph formed by O_1 and one-half of the image of the stellar spectrograph formed by O_2. A prism half silvered in this way is provided, which enables the observer to compare the equality of scale of both photographs. If, for example, it is found that the image of the solar spectrograph is the larger of the two it becomes necessary to adjust the object glass O_1 farther from the stellar spectrograph. This has the effect of forming the image of the latter farther from the observer's eye, and so it becomes necessary to turn the handle of the rack-pinion V in such a way as to move the prisms P_3 and P_4 nearer to P_2 till the lines of the stellar spectrograph are again sharply in focus. The effect of turning the pinion V is, of course, to displace the focus both of the solar and stellar spectrographs in the field of the eyepiece, but this displacement is easily restored by the focussing screws O_1 and O_2. By successive adjustments of this kind condition (3) can be accurately realized.

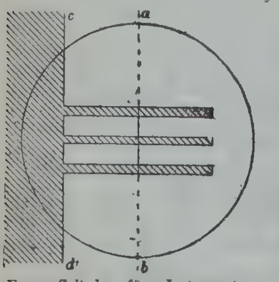
FIG. 23.



From *Zeitschr. für Instrumentenkunde*, by permission of Julius Springer, Berlin.
FIG. 24.

These three adjustments having been made, the prisms P_3 and P_4 are removed and replaced by another prism in which the silvering is arranged as in fig. 24, where the hatched lines denote the silvered surfaces. The narrow tongues of the silvered surface will now reflect corresponding parts of the star-spectrograph, and will obliterate corresponding parts of the solar spectrograph—as shown in figs. 25 and 26. Fig. 25 shows the stellar and solar lines of the two spectrographs in coincidence, whilst the metallic lines of comparison are non-coincident. Fig. 26 shows the metallic lines of comparison in coincidence whilst the solar and stellar lines are non-coincident. It is obvious that these two conditions can be produced at the will of the observer by simply turning the screw S, and that the difference of the readings of the screw-head, which are required to reproduce the two conditions in question, gives a measure of the displacement of the stellar lines relative to the solar lines. If then the screw-value in kilometres per second is known for the neighbourhood of each of the comparison lines employed, the radial velocity of the star can be independently derived directly from coincidences made in above manner in the neighbourhood of each comparison line. For the special purpose of determining the solar parallax this instrument has been used in a most refined and perfect manner by Dr Halm at the Cape of Good Hope (*Annals of the Cape Observatory*, vol. x. part 3).

Double Image Micrometers are described in the article HELIOMETER (*q.v.*). (D. GL.)

MICRONESIA (from Gr. μικρός, small, and νῆσος, island), one of the three great divisions of the oceanic islands in the central and western Pacific. Lying to the north of Melanesia, it embraces the following groups: Mariana, Pelew, Caroline, Marshall and Gilbert. See articles under these headings, and PACIFIC OCEAN (section on *Islands*).

The Micronesian islanders form in the main a branch of the Polynesian race, but distinguished from it by well-marked differences in appearance, language and institutions. Many of the islanders, however, show signs of hybridism. The proximity of Japan and the Philippines[1] on the west, and of the Papuan

The traditions of the Gilbert Islanders tell us that their islands and South Polynesian islands on the south and south-east, suggests, what in fact is found, a combination of races. In some places the oblique Mongolian eye is noticed, and (together with certain Indo-Chinese customs) there is often a scantiness of beard and general "Malay" look, which increases westwards, and seems to imply relations with the archipelago subsequent to the departure thence of the pure Polynesians. In the Gilberts the traces of Polynesian (Samoan) influences are evident, and are confirmed by tradition. Among the Carolines and the Marshalls darker and more savage communities are found, suggesting a Melanesian element, which is further traceable in the Ebon (Marshall) and other languages.

---

[1] There are authenticated instances of Japanese junks, with living people in them, having been found in various parts of the North Pacific. In 1814 the British brig "Forester" met with one off the coast of California (about 30° N. lat.), with three living men and fourteen dead bodies on board. In December 1832 a Japanese junk arrived at the Hawaiian Islands with four of the crew living. If these junks could cross the Pacific in the latitude of Hawaii it is not at all unlikely that others running in a south-easterly direction would reach some of the many atolls which stretch over about 35° of longitude, forming the Caroline and Marshall archipelagoes.

Each of the four main groups, viz. the Caroline, Marshall, Gilbert and Ladrone (Mariana), from long isolation, has developed ethnological peculiarities of its own. The most advanced folk were the "Chamorros" of the Ladrones, owing to the greater natural resources of the islands, and perhaps more frequent contact with influences from the west; but as a separate people they no longer exist, having been nearly exterminated by the Spaniards in the 17th century. Next in advancement come the Caroline islanders. The general Micronesian type is a well-proportioned rather slightly built figure, with small and regular features; head high and well proportioned, but forehead rather retreating and narrow at the temples; cheek bones and chin slightly prominent; straight black hair, lanker than that of the Polynesians, colour somewhat darker than the Polynesians, the Marshalls being darker and more vigorous than the Carolines, while the Gilbert type, though smaller than the latter, is still darker and coarser. The upper class greatly surpasses the common people in physique and intelligence.

There is a division of society into septs or clans, the membership of which constitutes the closest tie. Persons of the same sept must not intermarry, and when two islands or communities meet in war the members of one sept, however widely separated by distance of space or time, will not injure or fight with each other. Each community is usually composed (but there are local differences) of—(1) an upper class of chiefs, from among whom the head (*tamol* or *iros*) is chosen; (2) a lower but still noble class; and (3) common people, mostly without rights of property. These last are only allowed one wife. Here and there are traces, as in Tonga, of a spiritual sovereign, the descendants probably of a conquered dynasty. Succession is through the female side, which assures to women a certain position, and leads besides to some curious results (see paper by J. S. Kubary in *Das Ausland*, 1880, No. 27). The upper class are the keepers of traditions, boat-builders, leaders of expeditions; tattooing is generally done by them, the amount increasing with a man's rank; the custom here still has definite religious associations. Both sexes are tattooed.

The Marshall Islanders are the boldest and most skilful navigators in the Pacific. Their voyages of many months' duration, in great canoes sailing with outrigger to windward, well-provisioned, and depending on the skies for fresh water, help to show how the Pacific was colonized. They have a sort of chart, *medo*, of small sticks tied together, representing the positions of islands and the directions of the winds and currents. A two-edged weapon, of which the blade is of sharks' teeth, and a defensive armour of braided sennit, are also peculiar to the islands; a large adze, made of the shell of the *Tridacna gigas* (the largest bivalve known), was formerly used in the Carolines, probably by the old builder race.

The dialects of Micronesia, though grammatically alike, differ widely in their vocabularies. They have the chief characteristics of the Polynesian, with Malay affinities, and peculiarities such as the use of suffixes and inseparable pronouns and, as in Tagal, of the infix to denote changes in the verb; in the west groups there is a tendency to closed syllables and double consonants, and a use of the palatals *ch*, *j*, *sh*, the dental *th*, and *s* (the last perhaps only in foreign words), which is alien to the Polynesian. These letters are wanting in the Gilbert language, which differs considerably from all the others, and has much greater affinities with the Polynesian. Most words take the accent on the penult. In some of the dialects there appears to be no true article, but in the Gilbert Islands the Polynesian *te* is used for both definite and indefinite article. Gender is sexual only. Number in the noun is either gathered from the requirement of the sense or is marked by pronominal words or numerals. Case is known by the position of the noun in the sentence or by prepositions. In the language of Ebon, one of the islands in the Marshall archipelago, nouns have the peculiarity which is characteristic of the Papuan languages: those which indicate close relationship—as of a son to a father, or of the members of a person's body—take a pronominal suffix which gives them the appearance of inflexions. Many words are used indiscriminately as nouns, adjectives or verbs, without any change of form. In some languages the personal pronouns are singular, dual and plural. In others there are no special dual forms, but the numeral for two is used to indicate the dual. In the Ebon language there are inclusive and exclusive forms of the personal pronouns which, so far as has been ascertained, do not occur in any of the other languages. The verbs usually have no inflexions to express relations of voice, mood, tense, number of person—such distinctions being indicated by particles. In the Ebon language, however, the tenses are sometimes marked; but in that the simple form of the verb is frequently given. All have verbal directive particles. In Ponape, one of the Caroline Islands, many words of ceremony are used in addressing chiefs, as they are used in Samoa. The custom of tabooing words is also found there as it is in the Polynesian languages.

The religious myths are generally identifiable with the Polynesian, but a belief in the gods proper is overshadowed by a general deification of ancestors, who are supposed from time to time to occupy certain blocks of stone, set up near the family dwelling, and surrounded by circles of smaller ones. These stones are anointed with oil, and worshipped with prayer and offerings, and are also used for purposes of divination, in which, and in various omens, there is a general belief. In the Marshalls, in place of these stones, certain palm trees are similarly enclosed. The spirits also sometimes inhabit certain birds or fishes, which are then taboo, as food, to the family; but they will help to catch them for others. Temples are very rare, though these blocks of coral are sometimes surrounded by a roofless enclosure opening to the west. The bodies of the dead, and sometimes even of the sick, are despatched to sea westwards, with certain rites; those of the chiefs, however, are buried, for the order has something essentially divine about it; their bodies therefore are sacred, and their spirits naturally assume the position above described. Such a belief greatly strengthened the king's authority, for the spirits of his ancestors were necessarily more powerful than any other spirits. Thus too it comes that the chiefs, and all belonging to them, are taboo as regards the common people. There are various other subjects and occasions of taboo, but the institution has not the oppressive and all-pervading character which it has in Polynesia. Its action is often economical or charitable, *e.g.* the ripening coco-nuts are taboo as long as the bread-fruit lasts, thus securing the former for future use; or it is put on after a death, and the nuts thus saved are given to the family—a kindness to them, and a mark of respect for the dead.

The houses in the Gilberts and Marshalls (much less elaborate than in the Carolines) consist merely of a thatched roof resting on posts or on blocks of coral about 3 ft. high, with a floor at that level, which is reached from an opening in the centre. On this the principal people sleep, and it serves as a storehouse inaccessible to rats, which infest all the islands.

MICRONUCLEUS, the smaller nucleus in Infusoria (*q.v.*). In fission it divides by mitosis, and in conjugation furnishes the pairing or gametonuclei, by whose reciprocal fusion a zygote-nucleus is formed, which gives rise to the meganuclei and micronuclei of the individuals of the next cycle of fission.

MICROPEGMATITE, in petrology, a very fine intergrowth of quartz and alkali felspar, occurring as the last product of consolidation in many igneous rocks which contain high or moderately high percentages of silica. It shows the same structure on a minute scale as certain pegmatites (*q.v.*) or coarse granitic veins do on a large scale (see Petrology, Pl. 2, figs. 6 and 8); the quartz forms angular patches scattered through a matrix of felspar. In polarized light the separate areas of each mineral extinguish at the same time, and this proves that even though apparently discontinuous they have the same crystalline orientation. The felspar may be considered an irregular crystal of spongy structure, the interstices being filled up by another spongy crystal of quartz. This kind of mineral intergrowth is said to be "graphic," because the coarsely graphic veins have triangular quartz areas dotted over a felspathic background resembling certain primitive inscriptions. Micropegmatite differs from "graphic granite" only in being so much finer grained that its nature can only be detected with the microscope. The felspar of micropegmatite is usually orthoclase, but sometimes albite, oligoclase or microcline. Occasionally it has crystalline form, and then it has been proved that the quartz

---

were peopled from the west and also from the east. Those who came from the east are expressly said to be from Samoa. Those from the west were more numerous than those from the east. There are also traditions of the arrival of other strangers at some of these islands. On the island of Peru, in the Gilbert group, in 1869 there was still the remnants of a large proah which, from the description given, appears to have been like those used in the Indian Archipelago.

may be so disposed that the two minerals have a definite relation between their crystallographic axes (parallel growth). The quartz typically occurs as angular patches; at other times it forms club-shaped, curved or vermiform threads (vermicular micropegmatite, myrmekite), and then some authors consider that the felspar has been corroded and the quartz fills up the spaces thus produced (*quartz de corrosion* of French petrographers). Micropegmatite is often so fine grained that even in the thinnest sections and with high powers it cannot be resolved into its components. This fine micropegmatite resembles threads, having a divergent arrangement. In some rocks the whole ground mass consists of such spherulitic growths of fibrous micropegmatite (see QUARTZ—PORPHYRY); in their centres there is often a quartz or felspar crystal; the outer boundaries of the spherulites are not usually circular but irregular owing to the interlocking of adjacent spherulites at their margins ("granophyric structure"). Micrographic structures may occur in other minerals, *e.g.* quartz and garnet, cordierite, epidote or hornblende, augite and felspar, but are less common, and the name micropegmatite is usually reserved for aggregates of quartz and felspar.

In rocks where micropegmatite frequently occurs (*e.g.* granite, porphyry and granophyre, quartz-diorite) it is usually the last product of consolidation, and represents the mother liquor left over after the other minerals had separated out in more or less perfect crystals. Hence it has no definite form of its own, but fills up the irregular interspaces between the earlier crystallizations. For that reason it has been compared to a eutectic, and supposed to be the mixture of quartz and felspar which has the lowest fusion point. Eutectics are common in alloys and often have a very perfect micrographic structure. The eutectic mixture of quartz and orthoclase has been estimated to contain 70–75% of the latter. This theory, however, is not without its difficulties; analyses of micropegmatite prove that its composition is by no means constant (this may perhaps be due to small admixtures of soda and lime felspars); and experimental researches on the fusion points of mixtures of quartz and felspar have not yet shown that there is a definite mixture which melts at a lower temperature than any other. Furthermore micropegmatite is not always the last consolidation product, as a eutectic should be, but may occur as well-shaped phenocysts lying in a felsitic or glassy matrix which solidified at a still later time. Micrographic structures in the minerals of igneous rocks prove only that these minerals crystallized simultaneously. (J. S. F.)

MICROSCOPE (Gr. μικρός, small, σκοπεῖν, to view), an optical instrument for examining small objects or details of such objects; it acts by making the angles of vision under which the images appear greater than when the objects themselves are viewed by the naked eye.

Microscopes are distinguished as *simple* and *compound*. A simple microscope consists of a single positive lens, or of a lens combination acting as a single lens, placed between the eye and the object so that it presents a virtual and enlarged image. The compound microscope generally consists of two positive lens systems, so arranged that the system nearer the object (termed the *objective*) projects a real enlarged image, which occupies the same place relatively to the second system (the *eyepiece* or *ocular*) as does the real object in the simple microscope. An image is therefore projected by the ocular from the real magnified image produced by the objective with increased magnification.

History of the Simple Microscope.—Any solid or liquid transparent medium of lenticular form, having either one convex and one flat surface or two convex surfaces whose axes are coincident, may serve as a "magnifier," the essential condition being that it shall refract the rays which pass through it so as to cause widely diverging rays to become either parallel or but slightly divergent. Thus if a minute object be placed on a slip of glass, and a single drop of water be placed upon it, the drop will act as a magnifier in virtue of the convexity of its upper surface; so that when the eye is brought sufficiently near it (the glass being held horizontally) the object will be seen magnified. Again if a small hole be made in a thin plate of metal, and a minute drop of water be inserted in it, this drop, having two convex surfaces, will serve as a still more powerful magnifier. There is reason to believe that the magnifying power of transparent media with convex surfaces was very early known. A convex lens of rock-crystal was found by Layard among the ruins of the palace of Nimrud; Seneca describes hollow spheres of glass filled with water as being commonly used as magnifiers.

The perfect gem-cutting of the ancients could not have been attained without the use of magnifiers; and doubtless the artificers who executed these wonderful works also made them. Convex glass lenses were first generally used to assist ordinary vision as "spectacles"; and not only were spectacle-makers the first to produce glass magnifiers (or simple microscopes), but by them also the telescope and the compound microscope were first invented. During the Thirty Years' War the simple microscope was widely known. Descartes (*Dioptrique*, 1637) describes microscopes wherein a concave mirror, with its concavity towards the object, is used, in conjunction with a lens, for illuminating the object, which is mounted on a point fixing it at the focus of the mirror. Antony van Leeuwenhoek appears to be the first to succeed in grinding and polishing lenses of such short focus and perfect figure as to render the simple microscope a better instrument for most purposes than any compound microscope then constructed. At that time the "compass" microscope was in use. One leg of a compass carried the object, and the other the lens, the distance between the two being regulated by a screw. Stands were also in use, permitting the manipulation of the object by hand. Robert Hooke shaped the minutest of the lenses with which he made many of the discoveries recorded in his *Micrographia* from small glass globules made by fusing the ends of threads of spun glass; and the same method was employed by the Italian Father Di Torre. Early opticians and microscopists gave their chief attention to the improvement of the simple microscope, the principle of which we now explain.

SIMPLE MICROSCOPE

Position and Size of the Image.—A person with normal vision can see objects distinctly at a distance varying from ten inches to a very great distance. Objects at different distances, however, are not seen distinctly simultaneously, but in succession. This is effected by the power of accommodation of the eye, which can so alter the focal length of its crystalline lens that images of objects at different distances can be produced rapidly and distinctly one after another upon the retina.

The angle under which the object appears depends upon the distance and size of the object, or, in other words, the size of the image on the retina is determined by the distance and the dimensions of the object. The ratio between the real size of the object y (fig. 1) and the distance l, which is equal to the tangent of the visual angle w, is termed the "apparent size" of the object. From the figure, which represents vision with a motionless eye, it is seen that the apparent size increases as the object under observation is approached. The greater the visual angle, the more distinctly are the details of the object perceived. On the other hand, as the observer recedes from the object, the apparent size, and also the image on the retina diminishes; details become more and more confused, and gradually, after a while, disappear altogether, and ultimately the external configuration of the object as a whole is no longer recognizable. This case arises when the visual angle, under which the object appears, is approximately a minute of arc; it is due to the physiological construction of the retina, for the ends of nerve fibres, which receive the impression of light, have themselves a definite size. The lower limit of the resolving power of the eye is reached when the distance is approximately 3438 times the size of the object. If the object be represented by two separate points, these points would appear distinct to the normal eye only so long as the distance between them is at the most only 3438 times smaller than their distance from the eye. When the latter distance is increased still further, the two appear as one. Therefore when it is desired to distinctly recognize exceedingly small objects or details of such, they are brought as near as possible to the eye. The eye is strained in bringing its focal length to the smallest possible amount, and when this strain is long continued it may cause pain. When the shortest distance obtained by the highest strain of accommodation is insufficient to recognize small objects, distinct vision is possible at even a shorter distance by placing a very small diaphragm

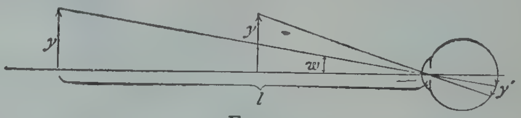

FIG. 1.

between the eye and the object, the pencils of rays proceeding from the object-points, which otherwise are limited by the pupils of the eye, being thus restricted by the diaphragm. The object is then projected with such acute pencils on the plane focused for, in this case on the plane on which the eye can just accommodate itself, that the circle of confusion arising there is still so small that it is below the limit of angular visual distinctness and on that account appears as a sharp point. However, the loss of light in this procedure is extraordinarily large, so that only most intensely illuminated objects can be investigated.

A naked short-sighted eye, which would be corrected for distant objects by a spectacle glass of −10 diopters, may approach the object up to about 4 in. and have a sharp image upon the retina without any strain whatever. For the observation of small objects, a myopic eye is consequently superior to a normal eye; and the normal eye in its turn is superior to the hypermetropic one. When the details are no longer recognizable by the unaided eye, the magnifying glass or the simple microscope is necessary. As a rule large magnification is not demanded from the former, but a larger field of view, whilst the simple microscope should ensure powerful magnification even when the field is small. The simple microscope enlarges the angle of vision, and does not tire the eye when it is arranged so that the image lies in the farthest limit of distinct vision (the *punctum remotum*). A normal eye will therefore see an image formed by the magnifying glass most conveniently when it is produced at a great distance, *i.e.* when the object is in its front focal plane. If y (fig. 2) be the object the image appears to a normal eye situated behind the system L with passive accommodation at a very great distance under the angle w'. Since $H'P = FO, = y$, from the focal length of the simple microscope, the visual angle w' is given by

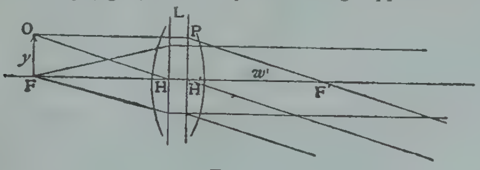

FIG. 2.

$$\tan w'/y = 1/f' = \mathrm{V}, \qquad (1)$$

in which $f', = H'F'$, is the image-side focal length (see LENS). Since the lens is bounded by air, the image- and object-side focal lengths f' and f are equal. The value $1/f'$ or V in (1), is termed the *power* of the lens. In most cases the number of "diameters" of the simple microscope is required; *i.e.* the ratio between the apparent sizes of the object when observed through the microscope and when viewed by the naked eye. When a person of normal vision views a small object, he brings it to the distance of distinct vision, which would average about 10 in. The apparent size is then (fig. 1) $\tan w = y/l$, where $l = 10$ in., whilst the apparent size of the object viewed through the magnifying glass would result from the formula (1) $\tan w' = y/f$. Consequently the number of diameters will be

$$\mathrm{N} = \tan w'/\tan w = y/f \,.\, l/y = l/f = \mathrm{V}.l; \qquad (2)$$

it is thus equal to the magnifying power multiplied by the distance of distinct vision, or the number of times that the focal length is contained in 10 in.

Since this value for the distance of distinct vision is only conventional, it is understood that the capacity of the simple microscope given in (2) holds good only for eyes accustomed to examine small objects 10 in. away; and observation through the magnifying glass must be undertaken by the normal eye with passive accommodation. A lens of 1 in. focal length must be spoken of, according to this notation, as a × 10 lens, and a lens of $\frac{1}{10}$ in. focal length as a × 100 lens. Obviously the position of a normal eye free from accommodation is immaterial for determining the magnification. A × 10 magnification is, however, by no means guaranteed to a myopic eye of −10 D by a lens of 1 in. focus. Since this short-sighted observer can view the object with the naked eye with no inconvenience to himself at 4 in. distance, it follows (to him) the apparent size is $\tan w = y/4$; and to secure convenient vision through the lens the short-sighted person would bring the object to such a distance that a virtual, magnified image would be projected in his *punctum remotum*. In addition it will be supposed that the centre of the pupil of the observer coincides with the back focal point of the system. The apparent size of the object seen through the lens is then $\tan w' = y/f$. The magnification, resulting from the simple microscope of 1 in. focus, is here $\mathrm{N} = \tan w'/\tan w = y/f \,.\, 4/y = 4/f = 4$. Thus, while a lens of 1 in. focal length assures to the normal-sighted person a × 10 magnification, it affords to the short-sighted individual only × 4. On the other hand, it is even of greater use to the hypermetropic than to the observer of normal sight. From this it appears that each observer obtains specific advantages from one and the same simple microscope, and also the individual observer can obtain different magnifications by either using different accommodations, or by viewing in passive accommodation.

Regulation of the Rays.[1]—In using optical instruments the eye in general is moved just as in free vision; that is to say, the attention is fixed upon the individual parts of the image one after another, the eye being turned in its cavity. In this case the eye is always directed so that the part of the image which is wished to be viewed exactly falls upon the most sensitive portion of the retina, viz. the *macula lutea* (yellow spot). Corresponding to the size of the yellow spot only a small fraction of the image appears particularly distinctly. The other portions which are reproduced on the retina on the regions surrounding the yellow spot will also be perceived, but with reduced definition. These external and less sensitive parts of the retina, therefore, merely give information as to the general arrangement of the objects and to a certain extent act as guide-post in order to show quickly and conveniently, although not distinctly, the places in the image which should claim special attention. Vision with a motionless eye, or "indirect vision," gives a general view over the whole object with particular definition of a small central portion. Vision with a movable eye, or "direct vision," gives exact information as to the parts of the object one after another.

The simple microscope permits such vision. If the instrument has a sensible lens diameter, and is arranged so that the centre of rotation of the eye can coincide with the intersection of the principal rays, the lens can then form with the eye a centred system. Such lenses are termed "lenses for direct vision." By moving the eye about its centre of rotation M the whole field can be examined. The margin of the mount of the lens serves as the diaphragm of the field of view. The selection of the rays emerging from the lens and actually employed in forming the image is undertaken by the pupil of the eye which, in this case, is consequently the exit pupil of the instrument. In fig. 3 $P'P'_1$ designates the exit pupil of the lens, and the image of $P'P'_1$, *i.e.* PP_1, which is formed by the lens, limits the aperture of the pencils of rays on the object-side; consequently it is the entrance pupil of the instrument. Since the exit pupil moves in observing the whole field, the entrance pupil also moves. The principal rays, which on the object-side connect the object-points with the centre of the entrance pupil, intersect the axis on the image-side at the centre of rotation M of the eye. M is therefore the intersection of the principal rays.

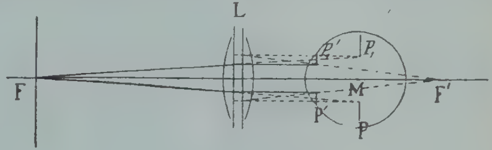

FIG. 3.

So long as the exit pupil is completely filled the brightness of the image will be approximately equal to that of free vision. If, however, we fix the points lying towards the margin of the field of view, the diaphragm gradually cuts off more and more of the rays which were necessary to fill the pupil, and in consequence the brightness gradually falls off to zero. This vignetting can be observed in all lenses.

In most cases, and also in corrected systems, the intersection of the principal rays is no longer available for the centre of rotation of the eye, and this kind of observation is impossible.

In some instruments observation of the whole available field is only possible when the head and eye are moved at the same time, the lens retaining its position. Dr M. von Rohr terms this kind of vision "peep-hole observation." It has mainly to be considered in connexion with powerful magnifying glasses. In most cases a diaphragm regulates the rays. Fig. 4 shows the position of the diaphragms to be considered in this kind of observation. PP_1 is the entrance pupil, $P'P_1'$ the exit pupil, and GG the diaphragm. The intersection of the principal rays in this case lies in the middle of the entrance pupil or of the exit pupil. By head and eye motion the various parts of the whole field can be viewed one after another. The distance of the eye from the lens is here immaterial. In this case also the illumination must fall to zero by the vignetting of the pencils coming from objects at the margin of the field of view. C and D are the outermost rays which can pass through the instrument.

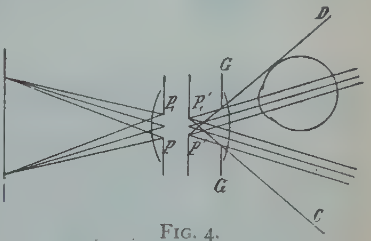

FIG. 4.

Magnifying glasses are often used for viewing three-dimensional objects. Only points lying on the plane focused for can be sharply reproduced in the retina, which acts as object-plane to the retina.

---

[1] See also LENS.

All points lying out of this plane are reproduced as circles of confusion. The central projection, of which the centre is the middle point of the entrance pupil on the plane focused for, will show in weaker systems, or those very much stopped down, a certain finite depth of definition; that is to say, the totality of points, which lie out of the plane focused for, and which are projected with circles of confusion so small that they appear to the eye as sharp points, will include the sharp object relief, and determine the depth of definition of the lens. With increasing magnification the depth of definition diminishes, because the circles of confusion are greater in consequence of the shorter focal length. Very powerful simple microscopes have hardly any depth of definition so that in fact only points lying in one plane can be seen sharply with one focusing.

Illumination.—So long as the pupil of the observer alone undertakes the regulation of the rays there is no perceptible diminution of illumination in comparison with the naked eye vision. The losses of light which occur in this case are due to reflection, which takes place in the passage of the light through the glass surfaces. In a lens with two bounding surfaces in air there is a loss of about 9%; and in a lens system consisting of two separated lenses, *i.e.* with four surfaces in air, about 17%. Losses due to absorption are almost zero when the lenses are very thin, as with lenses of small diameter. A very marked diminution in illumination occurs, however, when the exit pupil of the instrument is smaller than the pupil of the eye. In such instruments an arrangement is often required to intensely illuminate the object.

Forms of the Simple Microscope.—If the ordinary convex lens be employed as magnifying glass, great aberrations occur even in medium magnifications. These are: (1) chromatic aberration, (2) spherical aberration and (3) astigmatism (see ABERRATION).

When the pupil regulates the aperture of the rays producing the image the aberrations of the ordinary lenses increase considerably with the magnification, or, what amounts to the same thing, with the increase in the curvature of the surfaces. For lenses of short focus the diameter of the pupil is too large, and diaphragms must be employed which strongly diminish the aperture of the pencils, and so reduce the errors, but with a falling off of illumination. To reduce the aberrations Sir David Brewster proposed to employ in the place of glass transparent minerals of high refractive index and low dispersion. In this manner lenses of short focus can be produced having lower curvatures than glass lenses necessitate. The diamond has the requisite optical properties, its index of refraction being about 1·6 times as large as that of ordinary glass. The spherical aberration of a diamond lens can be brought down to one-ninth of a glass lens of equal focus. Apart, however, from the cost of the mineral and its very difficult working, a source of error lies in its want of homogeneity, which often causes a double or even a triple image. Similar attempts made by Pritchard with sapphires were more successful. With this mineral also spherical and chromatic aberration are a fraction of that of a glass lens, but double refraction, which involves a doubling of the image, is fatal to its use. Improvements in glass lenses, however, have rendered further experiments with precious stones unnecessary. The simplest was a sphere of glass, the equator of which (*i.e.* the mount) formed the diaphragm. Wollaston altered this by taking two plano-convex lenses, placing the plane surfaces towards each other and employing a diaphragm between the two parts (fig 5).

Wollaston. Brewster. Brewster (Stanhope).

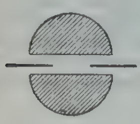

FIG. 5.

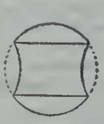

FIG. 6.

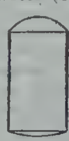

FIG. 7.

Sir David Brewster found that Wollaston's form worked best when the two lenses were hemispheres and the central space was filled up with a transparent cement having the same refractive index as the glass; he therefore used a sphere and provided it with a groove at the equator (see fig. 6). Coddington employed the same construction, and for this reason this device is frequently called the Coddington lens; although he brought the Wollaston-Brewster lens into general notice, he was neither the inventor nor claimed to be. This lens reproduced all points of a concentric spherical surface simultaneously sharp. A construction also employing one piece of glass forms the so-called Stanhope lens (fig. 7), which was really due to Brewster. This is a glass cylinder, the two ends of which are spherical surfaces. The more strongly curved surface is placed next the eye, the other serves at the same time as specimen carrier. This lens is employed in articles found in tourist resorts as a magnifying glass for miniature photographs of the locality.

Doublets, &c.—To remove the errors which the above lenses showed, particularly when very short focal lengths were in question, lens combinations were adopted. The individual components required weaker curvatures and permitted of being more correctly manufactured, and, more particularly, the advantage of reduced aberrations was the predominant factor.

Wollaston's doublet (fig. 8) is a combination of two plano-convex lenses, the focal lengths of which are in the ratio of 3 : 1; the plane sides are turned towards the object, and the smaller of the two lenses is nearer the object. This construction was further improved (1) by introducing a diaphragm between the two lenses; (2) by altering the distance between the two lenses; and (3) by splitting the lower lens into two lenses. Triplets are employed when the focal length of the simple microscope was less than $\frac{1}{10}$ in. When well made such constructions are almost free from spherical aberration, and the chromatic errors are very small. Similar doublets composed of two plano-convex lenses are the Fraunhofer (fig. 9) and the Wilson (fig. 10). Axial aberration is reduced by distributing the refraction between two lenses; and by placing the two lenses farther apart the errors of the pencils of rays proceeding from points lying outside the axis are reduced. The Wilson has a greater distance between the lenses, and also a reduction of the chromatic difference of magnification, but compared with the Fraunhofer it is at a disadvantage with regard to the size of the free working distance, *i.e.* the distance of the object from the lens surface nearer it.

Wilson.

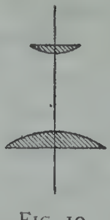

FIG. 10.

Steinheil.

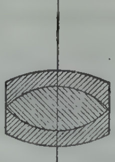

FIG. 11.

Chevalier (Brücke).

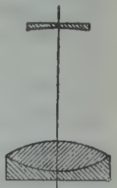

FIG. 12.

By introducing a dispersive lens of flint the magnifying glass could be corrected for both chromatic and spherical aberrations. Browning's "platyscopic" lens and the Steinheil "aplanatic" lens (fig. 11) are of this type. Both yield a field of good definition free from colour.

The manner in which the eye uses such a lens was first effectively taken into account by M. von Rohr. These anastigmatic lenses, which are manufactured up to × 40, are chromatically and spherically corrected, and for a middle diaphragm the errors of lateral pencils, distortion, astigmatism and coma are eliminated. "Peephole" observation is employed, observation being made by moving the head and eye while the lens is held steady. Even in powerful magnifications a good image exists in all parts of a relatively large field, and the free working distance is fairly large.

For especially large free working distances the corrections proposed by Chevalier and carried out by E. Brücke must be noticed (fig. 12). To an achromatic collective lens, which is turned towards the object, a dispersive lens is combined (this type to a certain extent belongs to the compound microscope). By altering the distance of the collective and dispersive members the magnification can be widely varied. Through the large free working distance, which for certain work offers great advantages, the size of the field of view is diminished.

In magnifying glasses for direct vision the eye must always be considered. The lens is brought as close as possible to the eye so as to view as large a field as possible. The watchmaker's glass is one of the earliest forms of this kind. Gullstrand showed how to correct these lenses for direct vision, *i.e.* to eliminate distortion and astigmatism when the centre of rotation of the eye coincided with the point where the principal rays crossed the axis. Von Rohr fulfilled this condition by constructing the Verant lens, which are low power systems intended for viewing a large flat field.

Stands.—For dissecting or examining objects it is an advantage to have both hands free. Where very short focus simple microscopes are employed, using high magnifications, it is imperative to employ a stand which permits exact focusing and the use of a special illuminating apparatus. Since, however, only relatively low powers are now employed, the ordinary rack and pinion movement for focusing suffices, and for illuminating the object only a mirror below the stage is required when the object is transparent, and a condensing lens above the stage when opaque.

Dissecting stands vary as to portability, the size of the stand, and the manner in which the arm-rests are arranged. A stand is shown in fig. 57 (Plate). On the heavy horseshoe foot is a column carrying the stage. In the column is the guide for the rack-and-pinion movement. Lenses of various magnifications can be adapted to the carrier and moved about over the stage. The rests can be attached to the stage, and when done with folded together. Illumination of transparent objects is effected by the universal-jointed mirror. By turning the knob A, placed at the front corner of the stage, a black or white plate, forming a dark or light background, can be swung underneath the specimen.

When the recognition of the arrangement in space of small objects is desired a stereoscopic lens can be used. In most cases refracting and reflecting systems are arranged so that the natural inter-pupillary distance is reduced. Stereoscopic lenses can never be powerful systems, for the main idea is the recognition of the depth of objects, so that only systems having a sufficient depth of definition can be utilized. Very often such stereoscopic lenses, owing to faulty construction, give a false idea of space, ignoring the errors which are due to the alteration of the inter-pupillary distance and the visual angles belonging to the principal rays at the object-side (see BINOCULAR INSTRUMENTS).

COMPOUND MICROSCOPE

The view held by early opticians, that a compound microscope could never produce such good images as an instrument of the simple type, has proved erroneous; and the principal attention of modern opticians has been directed to the compound instrument. Although we now know how the errors of lenses may be corrected, and how the simple microscope may be improved, this instrument remains with relatively feeble magnification, and to obtain stronger magnifications the compound form is necessary.

By compounding two lenses or lens systems separated by a definite interval, a system is obtained having a focal length considerably less than the focal lengths of the separate systems. If f and f' be the focal lengths of the combination, f_1, f_1' and f_2, f_2' the focal lengths of the two components, and Δ the distance between the inner foci of the components, then $f = -f_1 f_2/\Delta$, $f' = f_1' f_2'/\Delta$ (see LENS). Δ is also equal to the distance $F_1'F_2$. The accented f's are always on the image side, whilst the unaccented are on the object side. From this formula it follows, for example, that one obtains a system of $\frac{1}{8}$ in. focal length by compounding two positive systems of 1 in. each, whose focal planes, turned towards one another, are separated by 8 in.

A microscope objective being made in essentially the same way as a simple microscope, and the front focus of the compound system being situated before the front focus of the objective, the magnification due to the simple system makes the free object distance greater than that obtained with a simple microscope of equal magnification. Moreover, this distance between the object and eye is substantially increased in the compound microscope by the stand; the inconveniences, and in certain circumstances also the dangers, to the eye which may arise, for example by warming the object, are also avoided. The convenient and rapid change in the magnification obtained by changing the eyepiece or the objective is also a special advantage of the compound form.

In the commonest compound microscopes, which consist of two positive systems a real magnified image is produced by the objective. This permits researches which are impossible with the simple microscope. For example, the real image may be recorded on a photographic plate; it may be measured; it can be physically altered by polarization, by spectrum analysis of the light employed by absorbing layers, &c. The greatest advantage of the compound microscope is that it represents a larger area, and this much more completely than is possible in the simple form. According to the laws of optics it is only possible either to portray a small object near one of the foci of the system with wide pencils, or to produce an image from a relatively large object by correspondingly narrow pencils. The simple microscope is subject to either limitation. As we shall see later, one of the principal functions of the microscope objective is the representation with wide pencils. In that case, however, in the compound microscope a small object may always be represented by means of wider pencils, one of the foci of the objective (not of the collective system) being near it. For the eyepiece the other rule holds; the object is represented by narrow pencils, and it is hence possible to subject the relatively great object, viz. the magnified real image, to a further representation.

History of the Compound Microscope.—The arrangement of two lenses so that small objects can be seen magnified followed soon after the discovery of the telescope. The first compound miscroscope (discovered probably by the Middelburg lens-grinders, Johann and Zacharias Janssen about 1590) was a combination of a strong biconvex with a still stronger biconcave lens; it had thus, as well as the first telescope, a negative eyepiece. In 1646 Fontana described a microscope which had a positive eyepiece. The development of the compound microscope essentially depends on the improvement of the objective; but no distinct improvement was made in its construction in the two centuries following the discovery. In 1668 the Italian Divini employed several doublets, *i.e.* pairs of plano-convex lenses, and his example was followed by Griendl von Ach. But even with such moderate magnification as these instruments permitted many faults were apparent. A microscope, using concave mirrors, was proposed in 1672 by Sir Isaac Newton; and he was succeeded by Barker, R. Smith, B. Martin, D. Brewster, and, above all, Amici. More recently these catadioptric microscopes were disregarded because they yielded unfavourable results. From 1830 onwards many improvements were made in the miscroscope objective; these may be best followed from a discussion of the faults of the image.

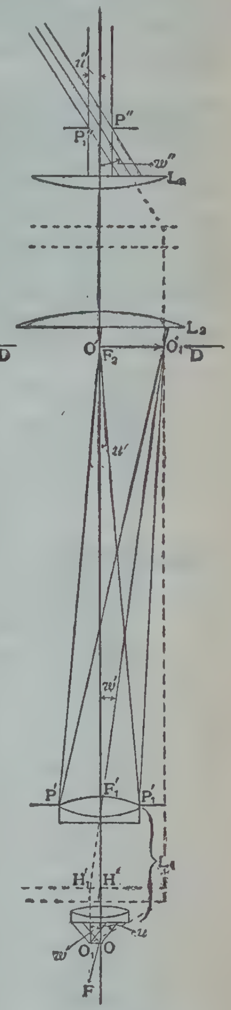

FIG. 13.—Ray transmission in compound microscope with a positive ocular.

L_1 = objective, L_2 L_3 = eyepiece of the Ramsden type.
F_1, F_1' = object- and image-side foci of objective.
F_2 = front focus of eyepiece.
$P'P_1'$ = exit pupil of objective.
$P''P_1''$ = exit pupil of complete microscope.
D D = diaphragm of field of view.

Position and Size of Image.—In most microscopic observations the object is mounted on a plane glass plate or slide about 0·06 in. thick, embedded in a liquid such as water, glycerine or Canada balsam, and covered with a plane glass plate of about 0·008 to 0·006 in. thick, called the cover-slip. If we consider the production of the image of an object of this kind by the two positive systems of a compound microscope shown in fig. 13, the objective L_1 forms a real magnified image $O'O_1'$; the object OO_1 must therefore lie somewhat in front of the front focus F_1 of the objective. Let $OO_1 = y$, $O'O_1' = y'$, the focal distance of the image $F_1'O' = \Delta$, and the image-side focal length f_1', then the magnification

$$M = y'/y = \Delta/f_1'. \qquad (3)$$

The distance Δ is called the "optical tube length."

Weak and strong microscope objectives act differently. Weak systems act like photographic objectives. In this case the optical tube length may be altered within fixed limits without spoiling the image; at the same time the objective magnification M is also altered. This change is usually effected by mounting the objective and eyepiece on two telescoping tubes, so that by drawing apart or pushing in the tube length is increased or diminished at will. For strong objectives there is, however, only one optical tube length in which it is possible to obtain a good image by means of wide pencils, any alteration of the tube length involving a considerable spoiling of the image. This limitation is examined below.

When forming an image by a microscope objective it often happens that the transparent media bounding the system have different optical properties. A series of objectives with short focal lengths are available, which permit the placing of a liquid between the cover-slip and the front lens of the objective; such lenses are known as "immersion systems"; objectives bounded on both sides by air are called "dry systems." The immersion liquids in common use are water, glycerine, cedar-wood oil, monobromnaphthalene, &c. Immersion systems in which the embedding liquid, cover-slip, immersion-liquid and front lens have equal refractive indices are called "homogeneous immersion systems." In immersion systems the object-side focal length is greater than the image-side focal length. Nothing is altered as to objective magnification, however, as the first surface is plane, and the employment of the immersion means that the value of f_1' is unaltered.

If we assume that a normal eye observes the image through the eyepiece, the eyepiece must project a distant image from the real image produced by the objective. This is the case if the image $O'O_1'$ lies in the front focal plane of the eyepiece. In this case the optical tube length equals the distance of the adjacent focal planes of the two systems, which equals the distance of the image-side focus of the objective F_1' from the object-side focus of the eyepiece F_2. The image viewed through the eyepiece appears then to the observer under the angle w'', and as with the single microscope

$$\tan w''/y' = 1/f_2' \qquad (4)$$

where f'_2 is the image-side focal length of the eyepiece.

To obtain the magnification of the complete microscope we must combine the objective magnification M with the action of the eyepiece. If we replace y' in equation (4) by the value given by (3), we obtain

$$\tan w''/y = \Delta/f_1' . 1/f_2'' = V, \qquad (5)$$

the magnification of the complete microscope. The magnification therefore equals the power of the joint system.

The magnification is also expressed as the ratio of the apparent size of the object observed through the microscope to the apparent size of the object seen with the naked eye. As the conventional distance for clear vision with naked eye is 10 in., it results from fig. 1 that the apparent size is $\tan w = y/l$. If this value of y be inserted in equation (5), we obtain the magnification number of the compound microscope:—

$$N = \tan w''/\tan w = \Delta l/f_1'f_2' = Vl. \qquad (6)$$

The magnification number increases then with the optical tube-length and with the diminution of the focal lengths of objective and eyepiece. As with the simple microscope, different observers see differently in the same compound microscope; and hence the magnification varies with the power of accommodation.

The image produced by a microscope formed of two positive systems (fig. 13) is inverted, the objective L_1 tracing from the object OO_1 a real inverted image $O'O'_1$, and the eyepiece L_2L_3 maintaining this arrangement. For many purposes it is immaterial whether the image is inverted or upright; but in some cases an upright image lightens the work, or may be indispensable.

The simplest microscope which produces an upright image has a negative lens as eyepiece. As shown in fig. 14, the real image formed by the objective must fall on the object-side focal plane of the eyepiece F_2, where a normal eye without accommodation can observe it. But as the object-side focus F_2 lies behind the eyepiece, the real image is not produced, but the converging pencils from the objective are changed by the eyepiece into parallels; and the point O_1 in the top of the object y appears at the top to the eye, *i.e.* the image is upright.

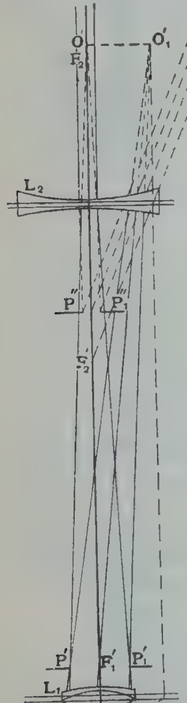

FIG. 14.—Ray transmission in compound microscope with a negative eyepiece.

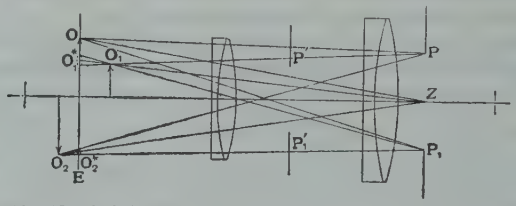
L_1 = weak achromatic objective.
L_2 = negative eyepiece.
F_1, F_1' = object- and image-side foci of objective.
F_2, F_2' = object- and image-side foci of eyepiece.
$P'P_1'$ = exit pupil of objective.
$P''P_1'$ = virtual image of P_1P_1' = exit pupil of complete microscope.

The erection of inverted images by prisms, which was applied to the simple telescope by Porro, and to the binocular (*q.v.*) by A. A. Boulanger was employed by K. Bratuscheck in the Greenough double microscope; these inverting prisms permit a convenient adaptation of the instrument to the interpupillary distance of the observer. Double microscopes, which produce a correct impression of the solidity of the object, must project upright images. The terrestrial eyepiece (see TELESCOPE), which likewise ensures an upright image, but which involves an inconvenient lengthening, has also been employed in the binocular microscope.

Regulation of the Rays.—Weak and medium microscope objectives work like photographic objectives in episcopic or diascopic projection; in the microscope, however, the projected image is not intercepted on a screen, but a real image in air is formed. This must lie in the front focal plane of the eyepiece if we retain the supposition that it is to be viewed by a normal eye with passive accommodation. The plane in the object conjugate to the focal plane of the eye-piece is the plane focused for; and all points in it are sharply portrayed (a perfect objective being assumed). Object points lying out of the focal plane, on the other hand, are projected as circles of confusion on the plane focused for, the centre of the entrance pupil being the centre of projection and the circles of confusion constituting, with the points of the focal plane, the object-side *imago*. As the pencils used in the representations are of wide aperture on the object-side, only such points as are proportionately very near the focal plane can produce such small dispersion circles on the plane focused for, that they, so far as the objective- and eyepiece-magnification permit, appear as points to the eye. It follows that the depth of definition of the microscope is in general very trifling. As it is entirely a function of the aperture and the magnification, it can be increased by diminishing the entrance pupil, the magnification remaining unchanged. A diminution of the aperture, however, would injure a very much more important property, viz. the resolving power (see below). With powerful systems, object-points lying quite near the plane focused for would be represented by such large dispersion circles that practically only the points lying in one plane appear simultaneously sharp; and it is only by varying the focus that the object-points lying in other planes can be observed.

The position of the diaphragm limiting the pencils proceeding from the object-points is not constant in the compound microscope. In all microscopes the rays are limited, not in the eyepiece, but in the objective, or before the objective when using a condenser. If the pencils are limited in the objective, the restriction of the pencil proceeding from the object-point is effected by either the front lens itself, by the boundary of a lens lying behind, by a real diaphragm placed between or behind the objective, or by a diaphragm-image.

The centre of the entrance pupil is the point of intersection of the principal rays; and it is therefore determinative for the perspective representation on the plane focused for. In fig. 15 the centre of the entrance pupil lies behind the focal plane, and consequently nearer objects appear larger, and farther objects smaller ("entocentric transmission," see below). If a diaphragm lying in the back focal plane of the objective forms the exit pupil for the objective, as in figs. 13 and 14, so that its image, the entrance pupil, lies at infinity, all the principal rays in the object-space are parallel to the axis, and we have on the object-side "telecentric" transmission. The size of the *imago* on the focal plane is always equal to its actual size, and is independent of the distance of the object from the plane focused for. This representation acquires a special importance if the object be micrometrically measured, for an inaccuracy in focusing does not involve an alteration of the size of the image. To ensure the telecentric transmission, the diaphragm in the back focus of the objective may be replaced by a diaphragm in the front focal plane of the condenser, supposing that uniformly illuminated objects are being dealt with; for in this case all the principal rays in the object-space are transmitted parallel to the axis.

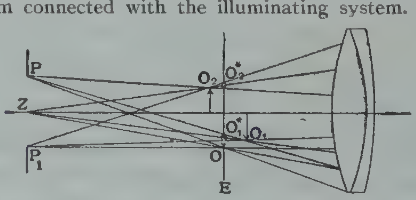


(After M. v. Rohr.)

FIG. 15.—Entocentric transmission through a microscope objective.

E = plane focused for; O_1^*, O_2^* = projections of O_1O_2 on E; Z = centre of projection; P P_1 = a virtual image of real diaphragm $P'P_1'$ with regard to the preceding part of the objective is the entrance pupil.

With uniformly illuminated objects it may happen that the pencil in the object-space may be limited before passing the object, either through the size of the source of light employed or through a diaphragm connected with the illuminating system. In fig. 16 the intersection of the principal rays lies in front of the object, and consequently objects in front of the plane focused for will be projected on E magnified and the objects lying behind it diminished ("hypercentric" transmission). It produces a perspective representation entirely opposed to ordinary vision. As objects lying near us appear smaller in the case of hypercentric transmission than those lying farther from us, we receive a false impression of the spatial arrangement of the object.



(After M. v. Rohr.)

FIG. 16.—Hypercentric transmission in a microscope objective.

E, O_1^*, O^* and Z as in fig. 15. PP_1 is the entrance pupil.

Whether the entrance pupil be before or behind the object, in general its position is such that it lies not too near the object, so that the principal rays will have in the object space only trifling inclinations towards one another or are strictly parallel. This is specially important, for otherwise pencils from points placed somewhat laterally to the axis arrive with diminished aperture at the image.

We see from fig. 13 that the objective's exit pupil $P'P_1'$ is portrayed by the positive eyepiece, the image $P''P_1''$ limits the pencils proceeding from the eyepiece. This image $P''P_1''$ is then the exit pupil of the combined system, and consequently the image of the entrance pupil of the combined system. As the exit pupil $P'P_1'$ for the objective lies before the front focus of the eyepiece, generally at some distance and near the objective, the eyepiece projects a real image from it behind its image-side focus, so that if this point is accessible it is the exit pupil $P''P_1''$. If, *e.g.* in the object-space the objective has telecentric transmission, the exit pupil must coincide with the back focal plane of the combined system, and it always lies behind the image-side focus of the eyepiece. The exit pupil, often called Ramsden's circle, is thus accessible to the observer, who by head- and eye-movements may survey the whole field.

We can now understand the ray transmission in the compound microscope, shown in fig. 13. Points of a small object (compared with the focus of the objective) send to the objective wide pencils. The diaphragm limiting them, *i.e.* the entrance pupil, is placed so that the principal rays are either parallel or slightly inclined. The pencils producing the real image are very much more acute, and their inclination is the smaller the stronger the magnification. The eyepiece, which by means of narrow pencils represents the relatively large real image at infinity, transmits from all points of this real image parallel pencils, whereby the inclination of the principal rays becomes further increased. The point of intersection, *i.e.* the centre of the exit pupil, is accessible to the eye of the observer. In the case of the negative eyepiece, on the other hand, the divergence of the principal rays through the eyepiece is also further augmented, but their point of intersection is not accessible to the eye. This property shows the superiority of the collective eyepiece over the dispersive.

The increase of the inclination of the principal rays, which arises with the microscope, influences the perception of the relief of the object. In entocentric transmission this phenomenon appears in general as in the case of the contemplation of perspective representations at a too short distance, the objects appearing flattened. Although in the case of the spatial comprehension of a perspective representation experience plays a large part, in observing through a microscope it does not count, or only a little, for the object is presumably quite unknown. In telecentric and hypercentric transmission we obtain a false conception of the spatial arrangement of the objects or their details; in these cases one focusses by turns on the different details, and so obtains an approximate idea of their spatial arrangement.

While the limiting of the pencil is almost always effected by the objective, the limiting of the field of view is effected by the eyepiece, and indeed it is carried out by a real diaphragm DD arranged in the plane of the real image $O'O_1'$ (fig. 13) projected from the objective. The entrance window is then the real image of this diaphragm projected by the objective in the surface conjugate to the plane focused for, and the exit window is the image projected by the eyepiece; this happens with the image of the object lying at infinity. The result must be that the field of view exhibits a sharp border. In the case of the dispersive eyepiece, on the contrary, no sharply limited field can arise, but vignetting must occur.

Illumination.—The dependence of the clearness of the image on the aperture of the system, *i.e.* on the angular aperture of the image-producing pencil, holds for all instruments.

The brightnesses of image points in a median section of the pencil are proportional to the aperture of the lens, supposing that the rays are completely reunited. This is valid so long as the pencil is in air; but if, on the other hand, the pencil passes from air through a plane surface into an optically denser medium, *e.g.* water or glass, the pencil becomes more acute and the aperture smaller. But since no rays are lost in this transmission (apart from the slight loss due to reflection) the brightness of the image point in the water is as large as that in air, although the apertures have become less. Fig. 17 shows a pencil in air, A, dispersing in water, W, from the semi-aperture u_1, or a pencil in water dispersing in air from the semi-aperture u_2. If the value of the clearness in air be taken as $\sin u_1$, then by the law of refraction $N = \sin u_1 / \sin u_2$, the value for the clearness in water is $N \sin u_2$. This rule is general. The value of the clearness of an image-point in a median section is the sine of the semi-aperture of the pencil multiplied with the refractive index of the medium.

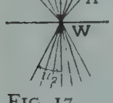


FIG. 17.

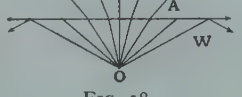

FIG. 18.

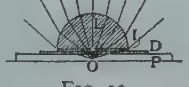

FIG. 19.

An illustration of this principle is the immersion experiment. A view taken under water from the point O (fig. 18) sees not only the whole horizon, but also a part of the bed of the sea. The whole field of view in air of 180° is compressed to one of 97·5° in water. The rays from O which have a greater inclination to the vertical than 48·75° cannot come out into the air, but are totally reflected. If pencils proceed from media of high optical density to media of low density, and have a semi-aperture greater than the critical angle, total reflection occurs; in such cases no plane surface can be employed, hence front lenses have small radii of curvature in order to permit the wide pencils to reach the air (see fig. 19, in which P is the preparation, O the object-point in it, D the cover slip, I the immersing fluid, and L the front lens).

The function $n \sin u = A$, for the microscope, has been called by Abbe the *numerical aperture*. In dry-systems only the sine of the semi-aperture is concerned; in immersion-systems it is the product of the refractive index of the immersion-liquid and the sine of the object-side semi-aperture. In the case of the brightness of large objects obviously the whole pencil is involved, and hence the clearness is the squares of these values, *i.e.* $\sin^2 u$ or $n^2 \sin^2 u$. As the semi-aperture of a pencil proceeding from an object point cannot exceed 90°, the numerical aperture of a dry-system cannot be greater than 1. On the other hand, in immersion-systems the numerical aperture can almost amount to the refractive index, for $A = n \sin u < n$. Dry systems of 0·98 numerical aperture, water immersion ($n = 1{\cdot}33$) from $A = 1{\cdot}25$, oil immersion ($n = 1{\cdot}51$) from $A = 1{\cdot}40$, and even α-bromnaphthalene immersions ($n = 1{\cdot}65$) from $A = 1{\cdot}60$, are available. In immersion-systems of such considerable aperture no medium of smaller refractive index than the immersion liquid may be placed between the surface of the front lens and the object, as otherwise total reflection would occur. This is especially inconvenient in the case of the α-bromnaphthalene immersion. As the embedding and immersing liquids must have equal refractive indexes, one must use α-bromnaphthalene for embedding; but this substance destroys organic preparations, so that one can employ this immersion-system only for examining inorganic materials, *e.g.* fine diatoms.

In immersion-systems a very much greater aggregate of rays is used in the representation than is possible in dry-systems. In addition to a considerable increase in brightness the losses due to reflection are avoided; losses which arise in passing to the back surface of the cover-slip and to the front surface of the front lens.

THE PHYSICAL THEORY

In order to fully understand the representation in the microscope, the process must be investigated according to the wave-theory, especially in considering the representation of objects or object details having nearly the size of a wave-length. The rectilinear rays, which we have considered above, but which have no real existence, are nothing but the *paths* in which the light waves are transmitted. According to Huygens's principle (see DIFFRACTION) each aether particle, set vibrating by an incident wave, can itself act as a new centre of excitement, emitting a spherical wave; and similarly each particle on this wave itself produces wave systems. All systems which are emitted from a single source can by a suitable optical device be directed that they simultaneously influence one and the same aether particle. According to the phase of the vibrations at this common point, the waves mutually strengthen or weaken their action, and there arises greater clearness or obscurity. This phenomenon is called interference (*q.v.*). E. Abbe applied the Fraunhofer diffraction phenomena to the explanation of the representation in the microscope of uniformly illuminated objects.

If a grating is placed as object before the microscope objective, Abbe showed that in the image there is intermittent clear and dark banding only, if at least two consecutive diffraction spectra enter into the objective and contribute towards the image. If the illuminating pencil is parallel to the axis of the microscope objective, the illumination is said to be direct. If in this case the aperture of the objective be so small, or the diffraction spectra lie so far from each other, that only the pencil parallel to the axis, *i.e.* the spectrum of zero order, can be admitted, no trace is generally found of the image of the grating. If, in addition to the principal maximum, the maximum of 1st order is admitted, the banding is distinctly seen, although the image does not yet accurately resemble the object. The resemblance is greater the more diffraction spectra enter the objective. From the Fraunhofer formula $\delta = \lambda / n \sin u$ one can immediately deduce the limit to the diffraction constant δ, so that the banding by an objective of fixed numerical aperture can be perceived. The value $n \sin u$ equals the numerical aperture A, where n is the refractive index of the immersion-liquid, and u is the semi-aperture on the object-side. For microscopy the Fraunhofer formula is best written $\delta = \lambda / A$. This expresses δ as the resolving power in the case of direct lighting. All details of the object so resolved are perceived, if two diffraction maxima can be passed through the objective, so that the character of the object is seen in the image, even if an exact resemblance has not yet been attained.

The Fraunhofer diffraction phenomena, which take place in the back focal plane of the objective, can be conveniently seen with the naked eye by removing the eyepiece and looking into the tube, or better by focusing a weak auxiliary microscope on the back focal plane of the objective. If one has, *e.g.* in the case of a grating, telecentric transmission on the object-side, and in the front focal plane of the illuminating system a small circular aperture is arranged, then by the help of the auxiliary microscope one sees in the middle of the back focal plane the round white image O (fig. 20) and to the right and left the diffraction spectra, the images of different colours partially overlapping. If a resolvable grating is considered, the diffraction phenomenon has the appearance shown in fig. 21.

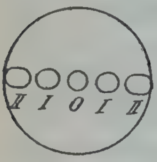

FIG. 20.

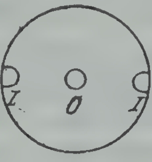

FIG. 21.

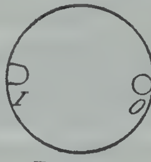

FIG. 22.

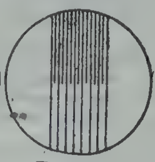

FIG. 23.

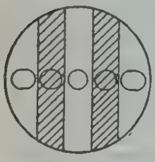

FIG. 24.

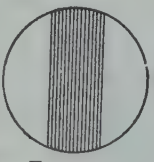

FIG. 25.

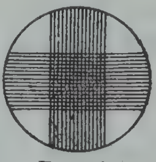

FIG. 26.

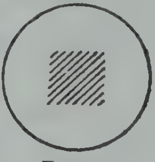

FIG. 27.

(From Abbe, *Theorie der Bilderzeugung im Mikroskop.*)

It is possible to almost double the resolving power, as in the case of direct lighting, so that a banding of double the fineness can be perceived, by inclining the illuminating pencil to the axis; this is controlled by moving the diaphragm laterally. If the obliquity of illumination be so great that the principal maximum passes through the outermost edge of the objective, while a spectrum of 1st order passes the opposite edge, so that in the back focal plane the diffraction phenomenon shown in fig. 22 arises, banding is still to be seen. The resolution in the case of oblique illumination is given by the formula $\delta=\lambda/2A$.

Reverting to fig. 13, we suppose that a diffracting particle of such fineness is placed at O that the diffracted pencils of the 1st order make an angle *w* with the axis; the principal maximum of the Fraunhofer diffraction phenomena lies in F'_1; and the two diffraction maxima of the 1st order in P′ and P'_1. The waves proceeding from this point are united in the point O′. Suppose that a well corrected objective is employed. The image O′ of the point O is then the interference effect of all waves proceeding from the exit pupil of the objective P_1P_1'.

Abbe showed that for the production of an image the diffraction maxima must lie within the exit pupil of the objective. In the silvering of a glass plate lines are ruled as shown in fig. 23, one set traversing the field while the intermediate set extends only half-way across. If this object be viewed by the objective, so that at least the diffraction spectra of 1st order pass the finer divisions, then the corresponding diffraction phenomenon in the back focal plane of the objective has the appearance shown in fig. 21, while the diffraction figure corresponding to the coarser ruling appears as given in fig. 20. If one cuts out by a diaphragm in the back focal plane of the objective all diffraction spectra except the principal maximum, one sees in the image a field divided into two halves, which show with different clearness, but no banding. By choosing a somewhat broader diaphragm, so that the spectra of 1st order can pass the larger division, there arises in the one half of the field of view the image of the larger division, the other half being clear without any such structure. By using a yet wider diaphragm which admits the spectra of 2nd order of the larger division and also the spectra of 1st order of the fine division, an image is obtained which is similar to the object, *i.e.* it shows bands one half a division double as fine as on the other. If now the spectrum of 1st order of the larger division be cut out from the diffraction figure, as is shown in fig. 24, an image is obtained which over the whole field shows a similar division (fig. 25), although in the one half of the object the represented banding does not occur. Still more strikingly is this phenomenon shown by Abbe's diffraction plate (fig. 26). This is a so-called cross grating formed by two perpendicular gratings. Through a suitable diaphragm in the back focal plane, banding can easily be produced in the image, which contains neither the vertical nor the horizontal lines of the two gratings, but there exist streaks, whose direction halves the angle under which the two gratings intersect (fig. 27). There can thus be shown structures which are not present in the object. Colonel Dr Woodward of the United States army showed that interference effects appear to produce details in the image which do not exist in the object. For example, two to five rows of globules were produced, and photographed, between the bristles of mosquito wings by using oblique illumination. In observing with strong systems it is therefore necessary cautiously to distinguish between spectral and real marks. To determine the utility of an objective for resolving fine details, one experiments with definite objects, which are usually employed simultaneously for examining its other properties. Most important are the fine structures of diatoms such as *Surirella gemma* and *Amphipleura pellucida* or artificial fine divisions as in a Nobert's grating. The examination of the objectives can only be attempted when the different faults of the objective are known.

If microscopic preparations are observed by diffused daylight or by the more or less white light of the usual artificial sources, then an objective of fixed numerical aperture will only represent details of a definite fineness. All smaller details are not portrayed. The Fraunhofer formula permits the determination of the most useful magnification of such an objective in order to utilize its full resolving power.

As we saw above, the apparent size of a detail of an object must be greater than the angular range of vision, *i.e.* 1′. Therefore we can assume that a detail which appears under an angle of 2′ can be surely perceived. Supposing, however, there is oblique illumination, then formula (5) can always be applied to determine the magnifying power attainable with at least one objective. By substituting *y*, the size of the object, for *d*, the smallest value which a single object can have in order to be analysed, and the angle *w*′ by 2′, we obtain the magnifying power and the magnification number:

$$V_2=\tan w'/d=2A\tan 2'/\lambda;\ N_2=2Al\tan 2'/\lambda;$$

where *l* equals the sight range of 10 in.

Even if the details can be recognized with an apparent magnification of 2′, the observation may still be inconvenient. This may be improved when the magnification is so increased that the angle under which the object, when still just recognizable, is raised to 4′. The magnification and magnifying number which are most necessary for a microscope with an objective of a given aperture can then be calculated from the formulae:

$$V_4=2A\tan 4'/\lambda;\ N_4=2Al\tan 4'/\lambda.$$

If 0·55 μ is assumed for daylight observation, then according to Abbe (*Journ. Roy. Soc.*, 1882, p. 463) we have the following table for the limits of the magnification numbers, for various microscope objectives, μ=0·001 mm.

$A=n\sin u$.	*d* in μ.	N_2.	N_4.
0·10	2·75	53	106
0·30	0·92	159	317
0·60	0·46	317	635
0·90	0·31	476	952
1·20	0·23	635	1270
1·40	0·19	741	1481
1·60	0·17	847	1693

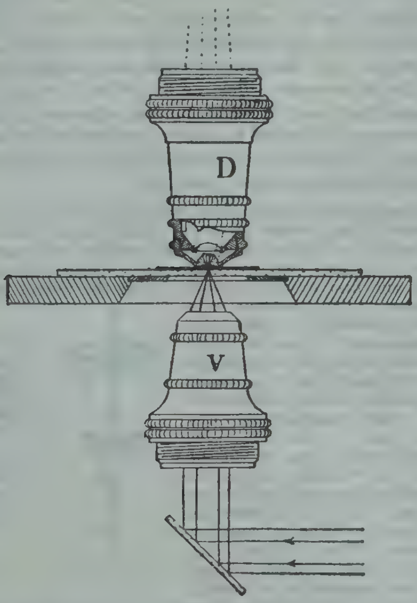
From this it can be seen that, as a rule, quite slight magnifications suffice to bring all representable details into observation. If the magnification is below the given numbers, the details can either not be seen at all, or only very indistinctly; if, on the contrary, the given magnification is increased, there will still be no more details visible. The table shows at the same time the great superiority of the immersion-system over the dry-system with reference to the resolving power. With the best immersion-system, having a numerical aperture of 1·6, details of the size 0·17 μ can be resolved, while the theoretical maximum of the resolving power is 0·167 μ, so that the theoretical maximum has almost been reached in practice. Still smaller particles cannot be portrayed by using ordinary daylight.

In order to increase the resolving power, A. Köhler (*Zeit. f. Mikros.*, 1904, 21, pp. 129, 273) suggested employing ultra-violet light, of a wave-length 275 μμ; he thus increased the resolving power to about double that which is reached with day-light, of which the mean wave-length is 550 μμ. Light of such short wave-length is, however, not visible, and therefore a photographic plate must be employed. Since glass does not transmit the ultra-violet light, quartz is used, but such lenses can only be spherically corrected and not chromatically. For this reason the objectives have been called monochromats, as they have only been corrected for light of one wave-length. Further, the different transparencies of the cells for the ultra-violet rays render it unnecessary to dye the preparations. Glycerin is chiefly used as immersion fluid. M. v. Rohr's monochromats are constructed with apertures up to 1·25. The smallest resolving detail with oblique lighting is $\delta=\lambda/2A$, where $\lambda=275$ μμ. As the microscopist usually estimates the resolving power according to the aperture with ordinary day-light, Köhler introduced the "relative resolving power" for ultra-violet light. The power of the microscope is thus represented by presupposing day-light with a wave-length of 550 μμ. Then the denominator of the fraction, the numerical aperture, must be correspondingly increased, in order to ascertain the real resolving power. In this way a monochromat for glycerin of a numerical aperture 1·25 gives a relative numerical aperture of 2·50.

If the magnification be greater than the resolving power demands, the observation is not only needlessly made more difficult, but the entrance pupil is diminished, and with it a very considerable decrease of clearness, for with an objective of a certain aperture the size of the exit pupil depends upon the magnification. The diameter of the exit pupil of the microscope is about 0·04 in. with the magnification N_3, and about 0·02 in. with the magnification N_4. Moreover, with such exceptionally narrow pencils shadows are formed on the retina of the observer's eye, from the irregularities in the eye itself. These disturbances are called "entoptical phenomena." From the section *Regulation of the Rays* (above) it is seen that the resolving power is opposed to the depth of definition, which is measured by the reciprocal of the numerical aperture, 1/A.

Dark-field Illumination.—It is sometimes desirable to make minutest objects in a preparation specially visible. This can be done by cutting off the chief maximum and using only the diffracted spectra for producing the image.

At least two successive diffraction maxima must be admitted through the objective for there to be any image of the objects. With this device these particles appear bright against a dark background, and can be easily seen. The cutting off of the chief maximum can be effected by a suitable diaphragm in the back focal plane of the objective. But, owing to the various partial reflections which the illuminating cone of rays undergoes when traversing the surfaces of the lenses, a portion of the light comes again into the preparation, and into the eye of the observer, thus veiling the image. This defect can be avoided (after Abbe) if a small central portion of the back surface of the front lens be ground away and blackened; this portion should exactly catch the direct cone of rays, whilst the edges of the lens let the deflected cone of rays pass through (fig. 28).



(By permission of C. Zeiss.)

FIG. 28.

The large loss of light, which is caused in dark-field illumination by the cutting off of the direct cone of rays, must be compensated by employing exceptionally strong sources. By dark-field illumination it is even possible to make such small details of objects perceptible as are below the limits of the resolving power. It is a similar phenomenon to that which arises when a ray of sunlight falls into a darkened room. The extremely small particles of dust (motes in a sunbeam) in the rays are made perceptible by the diffracted light, whilst by ordinary illumination they are invisible. The same observation can be made with the cone of rays of a reflector, and in the same way the fine rain-drops upon a dark background and the fixed stars in the sky become visible. It is not possible to recognize the exact form of the minute objects because their apparent size is much too small; only their presence is observable. In addition, the particles can only be recognized as separate objects if their apparent distance from one another is greater than the angular definition of sight.

Ultramicroscopy.—This method of illumination has been used by H. Siedentopf in his ultramicroscope. The image consists of a diffraction disk from whose form and size certain conclusions may be drawn as to the size and form of the object. It is impossible to get a representation as from an object. Very finely divided sub-microscopic particles in liquids or in transparent solids can be examined; and the method has proved exceptionally valuable in the investigation of colloidal solutions.

Siedentopf employed two illuminating arrangements. With the orthogonal arrangement for illuminating and observing the beam of light traverses an extremely fine slit through a well-corrected system, whose optic axis is perpendicular to the axis of the microscope; the system reduces the dimensions of the beam to about 2 to 4 μ in the focal plane of the objective. For the microscopic observation it is the same as if a thin section of a thickness of 2 to 4 μ had been shown. In this optical way it is possible to show thin sections even in liquid preparations. The inconvenience of orthogonal illumination, which certainly gives better results, is avoided in the coaxial apparatus. Care must here be taken, by using suitable dark-field screens, that no direct rays enter the observing system. The only sources of light are sunlight or the electric arc. The limit at which sub-microscopic particles are made visible is dependent upon the specific intensity of the source of light. With sunlight particles can be made visible to a size of about 0·004 μ.

Production of the Image.—As shown in LENS and ABERRATION, for reproduction through a single lens with spherical surfaces, a combination of the rays is only possible for an extremely small angular aperture. The aberrations, both spherical and chromatic, increase very rapidly with the aperture. If it were not possible to recombine in one image-point the rays leaving the objective and derived from one object-point, *i.e.* to eliminate the spherical and chromatic aberrations, the large angular aperture of the objective, which is necessary for its resolving power, would be valueless. Owing to these aberrations, the fine structure, which in consequence of the large aperture could be resolved, could not be perceived. In other words, a sufficiently good and distinct image as the resolving power permits cannot be arrived at, until the elimination, or a sufficient diminution, of the spherical and chromatic aberrations has been brought about.

The objective and eyepiece have such different functions that as a rule it is not possible to correct the aberrations of one system by those of the other. Such a compensation is only possible for one single defect, as we shall see later. The demands made upon the eyepiece, which has to represent a relatively large field by narrow cones of rays, are not very considerable. It is therefore not very difficult to produce a usable eyepiece. On the other hand, the correction of the objective presents many difficulties.

We will now examine the conditions which must be fulfilled by an objective, and then how far these conditions have been realized.

Consider the aberrations which may arise from the representation by a system of wide aperture with monochromatic light, *i.e.* the spherical aberrations. The rays emitted from an axial object-point are not combined into one image-point by an ordinary biconvex lens of fixed aperture, but the central rays come to a more distant focus than the outer rays. The so-called "caustic" occupies a definite position in the image-space. The spherical aberrations, however, can be overcome, or at least so diminished that they are quite harmless, by forming appropriate combinations of lenses.

The aberration of rays in which the outer rays intersect the axis at a shorter distance than the central rays is known as "under-correction." The reverse is known as "over-correction." By selecting the radii of the surfaces and the kind of glass the under- or over-correction can be regulated. Thus it is possible to correct a system by combining a convex and a concave lens, if both have aberrations of the same amount but of opposite signs. In this case the power of the crown lens must preponderate so that the resulting lens is of the same sign, but of a little less power. Correction of the spherical aberration in strong systems with very large aperture can not be brought about by means of a single combination of two lenses, but several partial systems are necessary. Further, under-corrected systems must be combined with over-corrected ones. Another way of correcting this system is to alter the distances. If, by these methods, a point in the optic axis has been freed from aberration, it does not follow that a point situated only a very small distance from the optic axis can also be represented without spherical aberration. The representation, free from aberration, of a small surface-element, is only possible, as Abbe has shown, if the objective simultaneously fulfils the "sine-condition," *i.e.* if the ratio of the sine of the aperture u on the object-side to the sine of the corresponding aperture u' on the image-side is constant; *i.e.* if $n \sin u/\sin u' = C$, in which C is a constant. The sine-condition is in contrast to the tangent-condition, which must be regarded as the point-by-point representation of the whole object-space in the image-space (see LENS), and according therefore the equation $n \tan u/\tan u' = C$ must exist. These two conditions are only compatible when the representation is made with quite narrow pencils, and where the apertures are so small that the sines and tangents are of about the same value.

Very large apertures occur in strong microscope objectives, and hence the two conditions are not compatible. The sine-condition is, however, the most important as far as the microscopic representation is concerned, because it must be possible to represent a surface-element through the objective by wide cones of rays. The removal of the spherical aberration and the sine-condition can be accomplished only for two conjugate points. A well-corrected microscope objective with a wide aperture therefore can only represent, free from aberrations, one object-element situated on a definite spot on the axis. As soon as the object is moved a short distance away from this spot the representation is quite useless. Hence the importance of observing the length of the tube in strong systems. If the sine-condition is not fulfilled but the spherical aberrations in the axis have been removed, then the image shown in fig. 19 results. The cones of rays issuing from a point situated only a little to the side, which traverse different zones of the objective, have a different magnification. The sine-condition can therefore also be understood as follows: that all objective zones must have the same magnification for the plane-element.

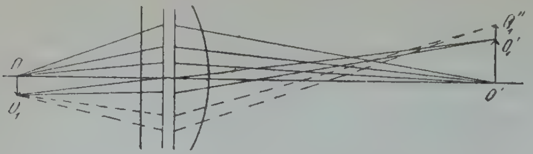


FIG. 29.—The lens is spherically corrected for OO′, but the sine-condition is not fulfilled. Hence the different magnifications of a point O₁ beyond the axis.

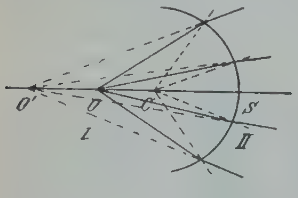

FIG. 30.—O′ is the virtual image of O formed at a spherical surface of centre C and radius CS.

According to Abbe, a system can only be regarded as aplanatic if it is spherically corrected for not only one axial point, but when it also fulfils the sine-condition and thus magnifies equally in all zones a surface-element situated vertically on the axis at this point.

A second method of correcting the spherical aberration depends on the notion of aplanatic points. If there are two transparent substances separated from one another by a spherical surface, then there are two points on the axis where they can be reproduced free from error by monochromatic light, and these are called "aplanatic points." The first is the centre of the sphere. All rays issuing from this point pass unrefracted through the dividing surface; its image-point coincides with it. Besides this there is a second point on the axis, from which all issuing rays are so refracted at the surface of the sphere that, after the refraction, they appear to originate from one point—the image-point (see fig. 30). With this, the object-point O, and consequently the image-point O′ also, will be at a quite definite distance from the centre. If however the object-point does not lie in the medium with the index n, but before it, and the medium is, for example, like a front lens, still limited by a plane surface, just in front of which is the object-point, then in traversing the plane surface spherical aberrations of the under-corrected type again arise, and must be removed. By homogeneous immersion the object-point can readily be reduced to an aplanatic point. By experiment Abbe proved that old, good microscope objectives, which by mere testing had become so corrected that they produced usable images, were not only free from spherical aberrations, but also fulfilled the sine-condition, and were therefore really aplanatic systems.

The second aberration which must be removed from microscope objectives are the chromatic. To diminish these a collective lens of crown-glass is combined with a dispersing lens of flint; in such a system the red and the blue rays intersect at a point (see ABERRATION). In systems employed for visual observation (to which class the microscope belongs) the red and blue rays, which include the physiologically most active part of the spectrum, are combined; but rays other than the two selected are not united in one point. The transverse sections of these cones of rays diverge more or less from the transverse section of the chosen blue and red cones, and produce a secondary spectrum in the image, and the images still appear to have a slightly coloured edge, mostly greenish-yellow or purple; in other words, a chromatic difference of the spherical aberrations arises (see fig. 31). This refers to systems with small apertures, but still more so to systems with large ones; chromatic aberrations are exceptionally increased by large apertures.

The new glasses produced at Schott's glass works, Jena, possessed in part optical qualities which differed considerably from those of the older kinds of glass. In the old crown and flint glass a high refractive index was always connected with a strong dispersion and the reverse. Schott succeeded, however, in producing glasses which with a comparatively low refraction have a high dispersion, and with a high refraction a low dispersion. By using these glasses and employing minerals with special optical properties, it is possible to correct objectives so that three colours can be combined, leaving only a quite slight tertiary spectrum, and removing the spherical aberration for two colours. Abbe called such systems "apochromats." Good apochromats often have as many as twelve lenses, whilst systems of simpler construction are only achromatic, and are therefore called "achromats."

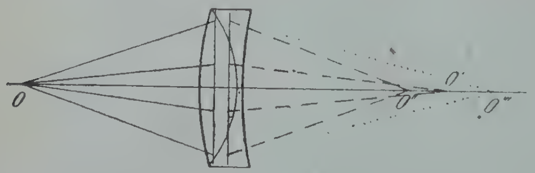

FIG. 31.—Showing a system with chromatic difference of spherical aberration. O″=image of O for red light; O‴ for blue. The system is under-corrected for red, and over-corrected for blue rays.

Even in apochromats it is not possible to entirely remove the chromatic difference of magnification, *i.e.* the images produced by the red rays are somewhat smaller than the images produced by the blue. A white object is represented with blue streaks and a black one with red streaks. This aberration can, however, be successfully controlled by a suitable eyepiece (see below).

A further aberration which can only be overcome with difficulty, and even then only partially, is the "curvature of the field," *i.e.* the points situated in the middle and at the edge of the plane object can not be seen clearly at the same focusing.

Historical Development.—The first real improvement in the microscope objective dates from 1830 when V. and C. Chevalier, at first after the designs of Selligue, produced objectives, consisting of several achromatic systems arranged one above the other. The systems could be used separately or in any combination. A second method for diminishing the spherical aberration was to alter the distances of the single systems, a method still used. Selligue had no particular comprehension of the problem, for his achromatic single systems were simply telescope objectives corrected for an infinitely distant point, and were placed so that the same surface was turned towards the object in the microscope objective as in the telescope objective; although contrary to the telescope, the distance of the object in the microscope objective is small in proportion to the distance of the image. It would have been more correct to have employed these objectives in a reverse position.

These circumstances were considered by Chevalier and Lister. Lister showed that a combination of lenses can be achromatic for only two points on the axis, and therefore that the single systems must be so arranged that the aplanatic (virtual) image-point O′ (fig. 32) of the first system coincides with the object-point of the next system. This system will always be aplanatic. These objectives permitted a much larger aperture than a simple achromatic system. Although such systems have been made recently for special purposes, this construction was abandoned, and a more complex one adopted, which also made the production of better objectives possible; this is the principle of the compensation of the aberrations produced in the different parts of the objective. Even Lister, who proceeded on quite different lines, hinted at the possibility of such a compensation. This method makes it specially possible to overcome the chromatic and spherical aberrations of higher orders and to fulfil the sine-condition, and the chief merit of this improvement belongs to Amici. He had recognized that the good operation of a microscope objective depended essentially upon the size of the aperture, and he therefore endeavoured to produce systems with wide aperture and good correction. He used chiefly a highly curved plano-convex front lens, which has since always been employed in strong systems. Even if the object-point on the axis cannot be reproduced quite free from aberration through such a lens, because aberrations of the type of an under-correction have been produced by the first plane outer limiting surface, yet the defects with the strong refraction are relatively small and can be well compensated by other systems. Amici chiefly employed cemented pairs of lenses consisting of a plano-convex flint lens and a biconvex crown lens (fig. 33), and constructed objectives with an aperture of 135°. He also showed the influence of the cover-slip on pencils of such wide aperture. The lower surface of the slip causes under-correction on being traversed by the pencil, with over-correction when it leaves it; and since the aberration of the surface lying farthest from the object, *i.e.* those caused by the upper surface preponderate, an over-corrected cone of rays enters the objective. The over-correction increases when the glass is thickened. In order to counteract this aberration the whole objective must be correspondingly under-corrected. Objectives with definite under-correction can however only produce really good images with glass covers of a specified thickness. With apertures of 0·90–0·95 differences of even 0·004–0·008 in. in the glass covers can be noticed by the deterioration of the image. In systems with smaller apertures variations of the thickness of the glass cover are not so

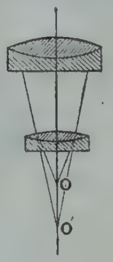

FIG. 32.

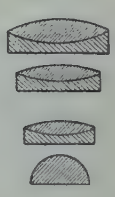

FIG. 33.

noticeable. For this reason Amici constructed objectives of a similar aperture and focus for different thicknesses of glass covers.

This expensive method was simplified in 1837 by Andrew Ross by making the upper and lower portion of the objective variable by means of a so-called correction-collar, and so giving the objective a corresponding under-correction according to the thickness of the glass cover. The alteration of the focus and the aperture are little influenced. The correction-collar was improved by Wenham and Zeiss, by working the upper system upon the lower, and not the reverse; for in this way the preparation remains almost exactly focused during the operation (see fig. 34).

The injurious influence of the glass cover is substantially lessened if no air is admitted to the space between the glass cover and the front lens (as in the dry-system) but if the intervening space is filled with an immersion-liquid. Amici was likewise the first to produce practical and good immersion-systems. The slight difference of the refractive indexes of the glass cover and the immersion-liquid involves a diminution of the aberrations, by which the objective will become less sensitive to the differences in thickness of the glass covers and admits of a more perfect adjustment. Water-immersion was introduced by Amici in 1840, and was improved by E. Hartnack in 1855.

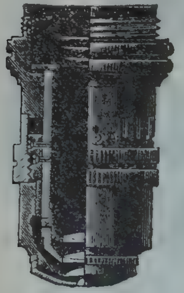

FIG. 34.—Objective fitted with correction collar (Zeiss).

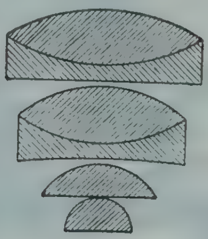

FIG. 35.—Achromatic objective for homogeneous immersion.

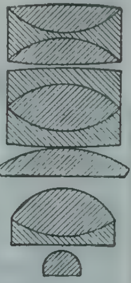

FIG. 36.—Apochromatic system.

The advantages of the immersion over the dry-systems are greatest when the embedding-liquid, the glass cover, the immersion-liquid and the front lens have the same refractive index. Such systems with a so-called homogeneous immersion were first constructed after the plan of E. Abbe in 1878 in the Zeiss workshops at the instigation of J. W. Stephenson. Cedarwood oil (Canada balsam), which has a refractive index of 1·515, is the immersion-liquid. The structure of a modern system of this type, with a numerical aperture of 1·30, is shown in fig. 35.

The most perfect microscope objective was invented by E. Abbe in 1886 in the so-called apochromatic objective. In this, the secondary spectrum is so much lessened that for all practical purposes it is unnoticeable. In the apochromats the chromatic difference of the spherical aberrations is eliminated, for the spherical aberration is completely avoided for three colours. Since in these systems the sine-condition can be fulfilled for several colours, the quality of the images of points beyond the axis is better. There still remains a slight chromatic difference in magnification, for although the magnification consequent upon the fulfilment of the sine-condition is the same for all zones for *one* colour, it is impossible to avoid a change of the magnification with the colour. Abbe overcame this defect by using the so-called compensation ocular, made with Jena glasses. Fig. 36 shows an apochromat of a numerical aperture of 1·40.

THE EYEPIECE OR OCULAR

The eyepiece is considerably simpler in its construction than the objective.

Its purpose in a microscope is by means of narrow cones of rays to represent at infinity the real magnified image which the objective produces. As, however, the object represents a real image, the problem is to project a transparent diapositive. It is therefore impossible to observe this image through an ordinary lens. Since many of the rays coming from the exit-pupil of the objective would not reach the eye of the observer at all, it is necessary, in order to make use of all of them, to direct the diverging rays forming the real image so that the whole of the light enters the eye of the observer. This is effected by a collective lens; it may be compared with the second part of the condenser system of a projecting lantern.

The two most customary eyepieces consist in two simple planoconvex lenses, whose distance one from the other is equal to half the sum of the two focal lengths. One of these is the Ramsden eyepiece (fig. 37). If the real image produced by the objective coincides with the collective lens, only the inclination of the principal rays is altered, the form of the cone being affected only to a very small extent. The lens nearer the eye, which has about the same focal length as the collective lens, is distant from it by about its focal length. The eye-lens converts diverging pencils into parallels. Both lenses together form the exit-pupil of the objective behind the eye-lens, so that this image, the exit-pupil of the total system or the Ramsden circle, is accessible to the eye of the observer. It is possible to see the whole field through this pupil by slightly moving the head and eye. In practice the real image is formed not directly on the collective lens but a little in front of it, because otherwise all the particles of dust on the collective would also be seen magnified.

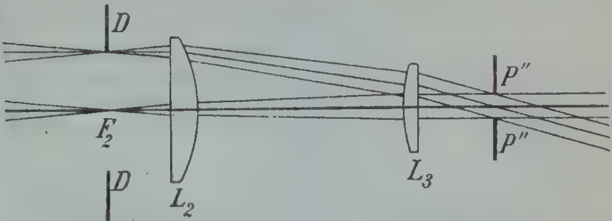

FIG. 37.—Ramsden Eyepiece.
L_2 = collective-, L_3 = eye-lens.
DD = diaphragm of the field of view.
$P''P''$ = Ramsden's circle, or exit-pupil of whole microscope.

In the other type, the Huygenian eyepiece (fig. 38), which is much more widely used, the collective lens is in front of the real image; it alters the direction of the principal rays and somewhat diminishes the real image. In this type the eye-lens is about twice as powerful as the collective lens, and makes the rays parallel. Here also the exit-pupil is accessible to the eye and through it the whole field can be seen by moving the head and eye. In both eyepieces micrometers or cross-wires are used for measuring in the plane of the real image. The Ramsden eyepiece is the most convenient for this because this plane lies in front of the collective lens, and the objective image has not yet been influenced by the eyepiece. As both eyepieces are used with very small apertures (about f: 20) no attempt has been made to overcome the spherical aberrations, which are usually very slight; neither, as a rule, are the eyepieces chromatically corrected, care has only to be taken by a suitable choice of the distance of one lens from the other, that the coloured images derived from a colourless object should have the same apparent size. Since, however, the difference of chromatic magnification cannot be overcome in powerful objectives, this error is still further increased by the eyepiece. The difference of chromatic magnification cannot even be overcome in apochromats, and to cancel this aberration Abbe devised the compensating ocular (fig. 39).

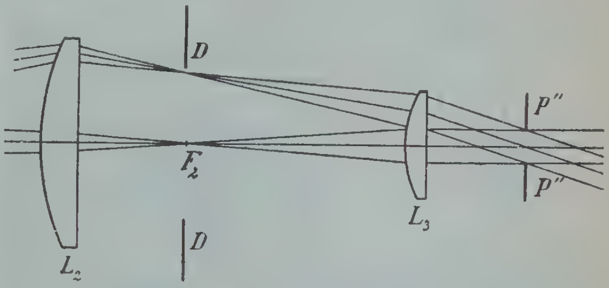

FIG. 38.—Huygenian Eyepiece.
L_2 = collective-, L_3 = eye-lens.
DD = diaphragm of the field of view.
$P''P''$ = Ramsden's circle, or exit-pupil of whole microscope.

The weak compensation oculars resemble a Huygenian eyepiece with achromatic eye-lens, whilst the more powerful ones are of a different construction. These eyepieces are intentionally provided with a different chromatic magnification, which however is in opposition to that originating in the objective. They have also a shorter focus for red, and a longer one for blue, and thus magnify the red image more than the blue; and as the objective gives a large blue and a small red image, the two cancel one another and a colourless image is produced.

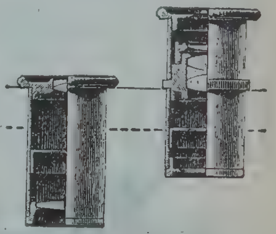

FIG. 39.—Compensating Eyepieces (Zeiss).

These eyepieces are very convenient in use, for when they are changed the lower focus always falls in about the same plane. In German and French microscopes the optical length of the tube, when apochromats and compensation-eyepieces are used, is 180 mm. By multiplying the magnification of the objective by the number on the eyepiece the total magnification of the microscope is obtained. By the magnification of the objective is meant the ratio of the distance of distinct vision to the focal length of the objective. As powerful achromatic objectives show differences of chromatic magnification in the same way as apochromats, compensation eyepieces can be used in combination with these objectives.

Illuminating Systems

Most microscopic observations are made with transmitted light; an illuminating arrangement is therefore necessary, and as the plane of the object is nearly always horizontal or only slightly inclined, the illuminating rays must be directed along the optical axis of the microscope.

To fully utilize the aperture of the system all dispersing rays in the object-space of the objective must be retained in the image-space of the illuminating system. When this occurs the greatest brightness will be obtained if the corresponding diaphragms of the two systems coincide; *i.e.* the field-diaphragm on the image-side of the observing system with object-side of the illuminating system, and the exit pupil of the illuminating system with the entrance pupil of the objective.

For slight magnifications a revolving plane mirror fixed below the object for altering the direction of the rays suffices. For this mirror to illuminate all the points of the objective so that the rays fill up the objective, it must not be too small, and should be as near as possible to the stage plate, and the source of light must be considerably extended (fig. 40). Diffused daylight is very suitable. If the aperture of the objective is increased, the diameter of the illuminating surface must also be increased so that the system is quite filled up, from which it follows that this method of illuminating soon fails. The possibilities of illuminating with a concave mirror seem a little more favourable. As a rule a concave mirror of similar aperture is fitted on the other side of the plane mirror. With the concave mirror an image of the source of light can be thrown upon the object. The distance of the concave mirror from the stage plate is about equal to its focal length. This is also the most suitable distance when diffused daylight is used, but it is too short with artificial light; the distance between the stage plate and the mirror should then be increased, so that an image of the source of light can be thrown upon the object. It is simpler to place an illuminating lens in front of the source of light so that the source falls approximately at the front focus of this lens and consequently is represented at infinity through the illuminating lens. By a correct choice of the focal length of the illuminating lens in relation to the focal length of the mirror, it is possible to choose the size of the image of the source of light so that the whole object-field is uniformly lighted.

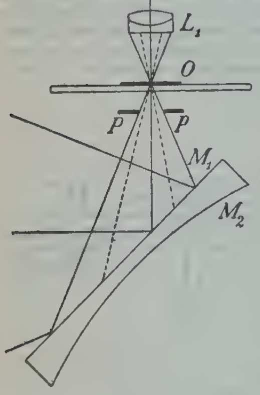

Fig. 40.—Mirror Illumination.
M_1 = plane-, M_2 = curved-mirror.
O = object; L_1 = front lens of microscope;
PP = diaphragm.

Too much light is useless for observing delicately coloured or colourless preparations, whose parts only become visible as a result of slight differences of diffraction. Then it is necessary to use powerfully concentrated cones of light. The apparatus must be such that the apertures of the illuminating rays can easily be altered, *e.g.* by inserting diaphragms in the course of the rays of the illuminating cone below the stage plate (fig. 40, *PP*). This concentration is most easily produced by sliding or revolving diaphragms. A series of holes of different sizes perforate a revolving disk below the stage plate at an equal radial distance from the axis of the disk, so that the holes can be brought under the preparation in turn, the centre of the diaphragms always being a continuation of the optical axis of the microscope.

The so-called cylinder diaphragms (fig. 41) are used especially in German microscopes. A changeable diaphragm is placed at the upper end of a short tube which can be moved in a case below the stage in the direction of the optical axis. By bringing the diaphragm nearer the object the aperture of the rays is increased; if the diaphragm is removed farther from the object the cone of rays is diminished (cf. fig. 40). These diaphragms are sometimes fitted in a slide, so that it is possible to move the diaphragm sideways and give oblique illumination (see below).

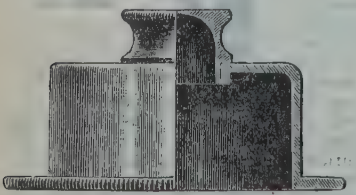

Fig. 41.—Cylinder Diaphragm (Zeiss).

With very powerful objectives these methods are insufficient; and a condenser is fitted below the stage plate. As a rule an iris diaphragm, which can be moved sideways, is now fitted below this condenser; below is the mirror which can be moved in all directions. The Abbe apparatus consists of a condenser, movable iris diaphragm, and mirror (fig. 42). The whole apparatus can be focused by a rack and the button *s*. The iris diaphragm can be regulated by the lever *p*; it can also be turned to one side round the pivot *z*, so that the condenser *k* can be removed or changed. The correct direction can be given to the illuminating cone by the mirror *m*. It is often desirable to pass from direct to oblique lighting. The Abbe apparatus makes this easy. The iris diaphragm *i* is pushed to the side by the rack and pinion *t n*. The chief cone of rays then enters obliquely into the objective, the angle between the direct cone of rays and the diffraction spectrum of the first order can then become as large again as with direct lighting, and still be taken up in the objective. Oblique lighting, however, can only be in an azimuth, so that the object must be turned in order that the details may be observed. Hence a condenser, for lighting with very oblique cones, must have about the same aperture as the objective, and therefore be of very wide aperture; they therefore closely resemble microscope objectives in construction. Especially powerful achromatic condensers are really only magnified microscope objectives, with the difference that they are not corrected for the thickness of the cover slip, but for the thickness of the glass on which the object is placed. For exceptionally accurate work microscope objectives are sometimes used as condenser systems. When using immersion objectives, an immersion condenser must also be used if rays of extreme obliquity are wanted, for, in consequence of the total reflections, rays can only come from the upper plane surface of the condenser, which have not a larger inclination to the axis than about 41°, varying according to the refractive index of the glass. In order to let highly inclined rays pass out from the condenser, some immersion liquid must be placed between the upper surface of the condenser and the object slide. Condensers are for this reason also constructed with apertures up to 1·40.

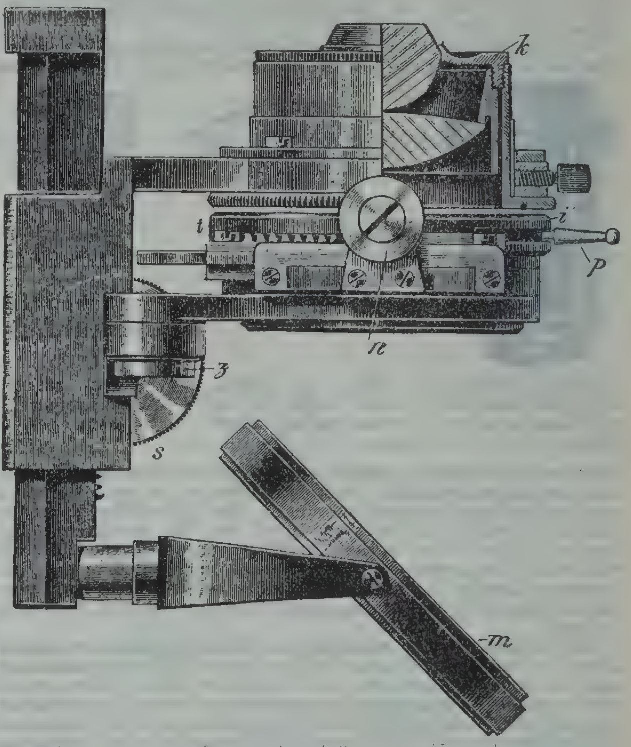

Fig. 42.—Abbe Illuminating Apparatus with Ordinary Condenser (Zeiss).

Vertical Illuminators.—Opaque objects can only be seen by reflected light. With low magnifying systems and a large free object distance, ordinary good daylight is sufficient. If the objects have a low reflecting power, or if a slightly higher magnification is needed, the lighting can be improved by optical system.

To examine small opaque objects with a high magnification the Lieberkühn mirror, so named after its inventor, was formerly much used. This was a concave mirror, pierced in the middle, fixed to the objective, and directed towards the object and with such a focal length that rays parallel to the axis falling upon it were united exactly upon the object. In this case the object lay upon a stage plate, whose centre had so far been made opaque, so that the rays coming from the illuminating plane mirror could not reach the objective direct, but only the rays passing the stage plate to the side of this blackened portion reached the Lieberkühn mirror, and were used in lighting. The disadvantage of this method was that only *small* opaque objects could be examined. Much more easily manipulated is the parabolic side-illuminator invented by R. Beck, which can be conveniently fitted in and used for objectives with different focal lengths. It consists in half of a short focused parabolic mirror, which concentrates all the light coming from the one side on to the object. To examine objects with objectives of high power and low free object distance, the apparatus for side-illumination is not sufficient, and a so-called vertical illuminator is used. In Zeiss's form (fig. 43) a small prism *p*, which also revolves upon a horizontal axis, is placed as near as possible to the back lens of the objective. The edge which is the separating line of the horizontal and hypothenuse surfaces of the prism, lies approximately over the middle of the system, so that the rays entering through the opening in the side after having been reflected by the hypothenuse surface are concentrated through one half of the objective on to the object. When observing only the other half of the objective is used. The sources of light used should be arranged so that the objective throws an image of the light-source upon the object. It is best if the image of the light is not larger than the object examined, and to effect this, an illuminating lens with an iris diaphragm is often placed between the source of light and the illuminator. By suitable adjustment and by changing the iris diaphragm the size of the illuminating field can be controlled. The objects observed with the vertical illuminator must not have a glass cover if the dry system is employed, because the upper surface of the glass cover would send so much light back into the objective by reflection, that the image would be indistinct. It is, on the contrary, possible to examine covered objects with the vertical illuminator, if the immersion system be employed. Owing to the slight difference of illumination between the immersion liquid and the cover, the portion of light reflected on the cover is not noticeable.

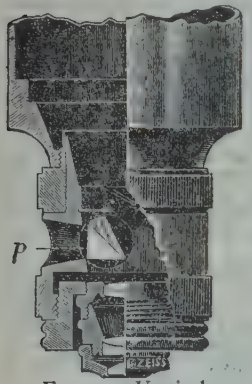

FIG. 43.—Vertical Illuminator (Zeiss).

Dark Field Illumination.—As was seen when discussing the physical theory, the minute details of the object cause diffractions, and can only be examined if the objective can take up at least two consecutive diffraction spectra. These diffracting details become especially distinct if the direct lighting cone of rays, the spectrum of zero order or the chief maximum, is not allowed to enter the objective and instead only two or more diffraction maxima are taken up; the details then appear bright on a dark background. In dark field illumination care has to be taken that no direct rays reach the objective, and hence a good dark field illumination can be produced if the condenser system has a larger aperture than the objective. If an Abbe lighting apparatus is used a dark field diaphragm (fig. 44) can be placed in the iris diaphragm case. The central diaphragm disk keeps away all the light which would otherwise fall directly into the objective, and the open zones send so many oblique rays through the object that they cannot all be taken up by the objective. Exactly the same effect is reached when, as is shown in Fig. 45, a more powerful system D is used for a condenser, which has a blackened section on the back of the front lens of such a size that no light can enter the objective A. In this way it is only possible for diffracted rays to enter the objective.

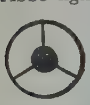

FIG. 44.

Apparatus for a good dark field illumination has received much attention, because in this way ultra-microscopical particles can be made visible. This depends on the good combination of the entering cones of rays, which should be as oblique as possible; this is most easily done by mirror condensers. A number of early inventions have been revived for this purpose.

Wenham's paraboloid illuminator (fig. 46) is made entirely of glass, and is in the form of a paraboloid, having on the top a spherical hole, of such a curvature that all entering rays, *r r′ r″*, parallel to the axis, after their reflection on the surface of the paraboloid, traverse the spherical surface perpendicularly and unite in F, the centre of the sphere. A diaphragm *s* is placed in the middle of the spherical surface, and this keeps back the central rays. This diaphragm is sometimes fixed to a handle piercing the condenser, and which can be moved up and down, so that the aperture of the oblique entering cones of rays can be altered. Another form of the paraboloid condenser, also due to Wenham, has a plane surface on the upper side. Some immersion fluid must then be placed between the stage plate and the condenser in order to allow all the rays to pass out; otherwise only those rays would be able to pass out which are close to the axis of the condenser in the inside of the condenser, and are smaller than the limiting angle of the total reflection.

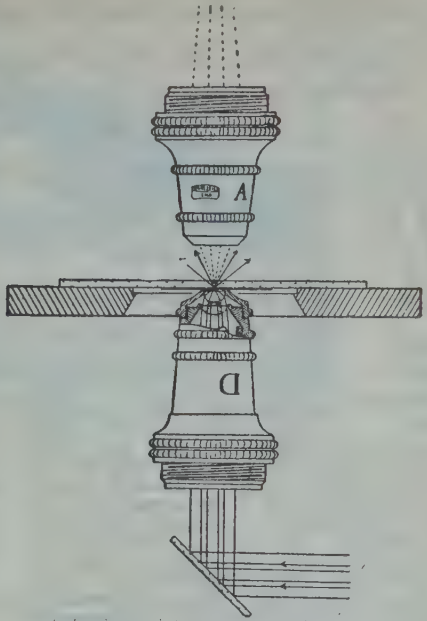

FIG. 45.—Path of Rays for dark-ground illumination with fixed diaphragm in the objective.

(Objective D can also be used as a condenser (Zeiss).)

Th. Ross's "spot lens," invented in 1855, and J. W. Stephenson's catoptric illuminator (1879), may also be mentioned. A recent condenser of very high illuminating power is due to H. Siedentopf (fig. 47). It is a double mirror system, whose reflecting surfaces are a sphere *a* and a cardioid *b*. The combination of rays is also sufficient in practice if the cardioid surface is replaced by a spherical one.

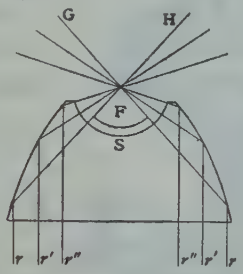

FIG. 46.—Wenham's Paraboloid Condenser.

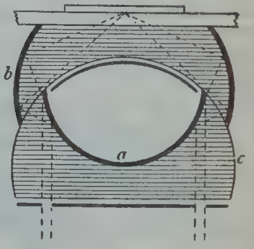

FIG. 47.—Siedentopf's Cardioid Condenser.

A supplementary spherical surface *c* is necessary for the completion of the condenser.

BINOCULAR INSTRUMENTS

The stereoscopic microscope is the most suitable for finding out the space taken up by the separate parts of a preparation. (See also BINOCULAR INSTRUMENTS and STEREOSCOPY.) The observer has a stereoscopic impression of an object, when different perspective representations are presented to both eyes, which, through the action of the central nerve system, resolve into one impression.

One way of receiving a stereoscopic impression through a microscope is by fixing an apparatus as directly as possible above the last lens of the microscopic objective, which divides the rays passing out and directs half into each eyepiece. The half cones of rays have now semicircular sections, the diaphragms having the same form. The cones must be so directed through the divided system that the two exit pupils correspond to the interpupillary distance of the observer. The distance of the centres of the semicircular entrance pupils and their distance from the object regulates the difference of the two perspective representations, which are presented one to the right eye and one to the left. If the perspective centres lie too near one another in the object-space, as may happen with slightly opened and weak systems, the difference of the perspective is then too slight to make any real stereoscopic impression. On the other hand, a very much exaggerated stereoscopic effect can be derived from short focused systems of wide aperture. On account of the slight depth definition, short focused systems of wide aperture are not at all specially suitable for stereoscopic observation, because the possibility of observing objects taking up a good deal of space is too limited when such systems are used.

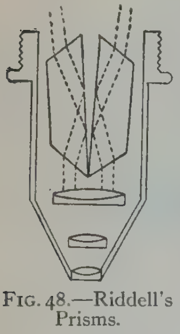

FIG. 48.—Riddell's Prisms.

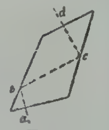

FIG. 49. Wenham's Prism.

Professor J. L. Riddell (*Quart. Journ. Micros*, 1853, p. 236; 1854, pp. 18–24) published an arrangement of prisms, which, however, imparted a pseudomorphous impression if image-forming oculars were not used, and in 1854 a second system (fig. 48), essentially a Wheatstone pseudoscope, added just above the objective. This gave an orthoscopic image even in ordinary eyepieces. By adopting right-angled reflection-prisms above the eyepiece he completely erected the image. Stephenson's stereoscopic microscope (fig. 58, Plate) resembles this apparatus in all essentials. A construction of prisms by Nachet is now almost forgotten, while on the contrary an extremely simple dividing prism published by Wenham (*Lond. Micros. Soc.*, 1861, i. 109) has been exceptionally well attested in practice. It is more easily used than any other apparatus (see BINOCULAR INSTRUMENTS, fig. 8). A reflection-prism (fig. 49) in a setting is placed above the last surface of the objective and divides the exit rays. The group of rays coming from the left half of the objective can continue its way without hindrance to the right eye. The group of rays coming from the right half of the objective is reflected twice in the prism and directed to the left eye. The tube containing the left eyepiece is a little inclined towards the right tube, which is perpendicular. It can be adapted to the interpupillary distance by changing the tube slide. If it is desired to use the instrument as a monocular, the setting with the prism at the lower end of the tube is taken away.

A second manner of making stereoscopic observations employs stereoscopic eyepieces. The first of such eyepieces was proposed by R. B. Tolles.[1] He realized that the division of the cones of rays by prisms could only be satisfactorily performed if the prism was placed in the position of the exit pupil of the objective or in the position of the real image of this exit pupil. He employed a Nachet combination of prisms and placed the dividing prism at the spot where a special reversing system formed a real image of the exit pupil of the objective. A second stereoscopic eyepiece was devised by A. Prazmowski who substituted a Wenham diffracting division prism at the position of the real image of the exit pupil of the objective formed by a reversing system. The newest form of a stereoscopic microscope resembles the oldest in so far as two completely separate microscopes are used. In the oldest microscope by Cherubin d'Orleans the observer receives a pseudoscopic impression in consequence of the reversed image. This defect has been avoided in the instruments constructed in the Zeiss factory (fig. 59, Plate) at the instigation of the American zoologist H. S. Greenough. The system of Porro prisms employed affords a convenient method of adapting the ends of the eyepieces to the interpupillary distance. The two tubes are inclined to one another at an angle of about 14°. The microscope is only intended for slight magnifications. The possibility already suggested of using both eyes for observing without having a stereoscopic impression, is often regarded as a great advantage. Binocular microscopes have therefore been constructed on this plan. Such a combination of prisms was used by Wenham, who placed it directly behind the last objective lens. As a rule this arrangement of prisms can be exchanged for the Wenham stereoscopic reflection-prisms.

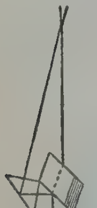

FIG. 50. Powell's Prisms.

A second kind of dividing prism which directs the entire course of rays to both eyes, and thus produces identical images, was used by Powell and Lealand (fig. 50). Every ray is divided into a reflected and a refracted portion on the front side of a parallel plate. Whilst the refracted portion after leaving the plate continues its way in the same direction, displaced a little to one side, the reflected portion is directed into the side tube by a reflection-prism. With these microscopes, which are not stereoscopic, objectives of any power can be used. The surfaces of the dividing prisms must be very exact, so that no deterioration of the image may arise from them. A microscope for two eyes can also be obtained by employing the Abbe stereoscopic eyepiece.

By the supplementary use of one of Wenham's prisms every ray is analysed into a more powerful refracted and a weaker reflected one. The same image can be presented to each eye by using this eyepiece also. No stereoscopic impression is then felt. It is brought about by placing special semicircular diaphragms in the plane of the exit pupil of the microscope. By turning the diaphragms 180° round the optical axis, the orthoscopic impression can be changed into the pseudoscopic. The mechanical arrangement of the eyepiece is such that the distance of the two exit pupils can be adjusted to the interpupillary distance.

MECHANICAL ARRANGEMENTS

Although the optical system is the first consideration in a microscope, the system is valueless if the fittings do not allow its correct use. The optical system must be kept at a certain distance and well centred, and a correct position for the object in relation to the system must be assured.

In fig. 60, Plate, the microscope is seen to consist of the heavy metal foot A, which rests on the table at three points. The whole microscope is fitted to this foot. The object can be held firmly on the stage plate B by cramps C. On the lower side of the stage plate are the condenser and the diaphragms, and the illuminating mirror J is held by a rod D fixed to the stage plate. Likewise on the stage plate is the support for the tube E. The rough adjustment of the microscope can be made by a rack and pinion F; and the fine adjustment by the screw G. The tube containing the eyepiece and the objective is double. The inner tube H is movable, making a change in the length of the tube possible. As a rule this inner tube has a mark which allows the length of the tube to be set.

It is most important the stand should be free of vibration. A fine adjustment is also necessary, in order to perform conveniently and with certainty the slight motion of the microscope in relation to the object. In cheap stands the rough adjustment was worked by moving the inner tube by hand, but the more convenient rack and pinion is now used almost exclusively.

For slight magnifications rough adjustment is sufficient, but with objectives of a focus below $\frac{1}{4}$ in., a fine adjustment is wanted. Very different constructions are in use. Almost all are such that the whole microscope tube is raised or sunk by the mechanism of the fine adjustment, and not only the objective. The most used is the micrometer screw adjustment (fig. 51). The tube carrier B fits closely on to a column A which is fixed firmly to the stage plate. The end of the column C is traversed by the micrometer screw D which is set in action by the knob E. The column A contains a powerful spiral spring, which exercises a strong pressure on the plate F fixed to the carrier B. By screwing in the micrometer, the spring is compressed and the tube lowered. By the contrary movement the spring pressure raises the tube as far as is allowed by the screw. The strong pressure of the spring practically excludes motion, which with fine adjustments is very important. Another very good adjustment is that of Messrs Swift & Son, shown in fig. 52. The long lever D is pressed to one side by the screw F, and is thus turned round the pin E. On the tube very near to the pin E is a cylinder C, which by the action of the screw F is very slightly raised or lowered. A double lever is used in a fine adjustment by Messrs Watson & Sons (fig. 53). According to whether the screw A or B is used, the adjustment is fine or coarse. In other fine adjustments by means of springs and balance wheels either a micrometer screw is moved (Zeiss), or a curved disk fixed to the balance wheel is turned (Leitz), or an oblique disk arranged more or less in a circle and attached to the balance wheel is revolved (Reichert). These modern adjustments are made so exact that motions can be easily measured

up to 0·002 mm. An essential in all rough and fine adjustments is that the motion must always be parallel to the optical axis of the microscope, so that the same point in the object remains in the centre of the field.

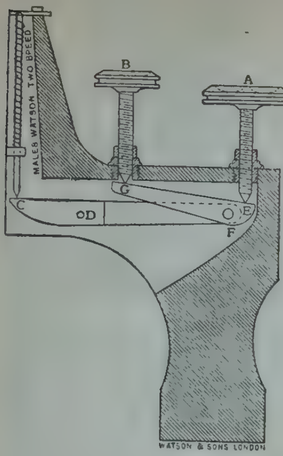

Fig. 53.—Double Lever Adjustment of Watson & Sons.

Another condition which must be fulfilled by a good stand is the power of inclination. It is only rarely necessary to arrange the preparation really horizontal; and for easy observation, especially when it will take a long time, it is of great assistance if the microscope can be inclined, so that the observations can be made in a natural position. The apparatus for inclining the microscope is chiefly such, that the microscope can be placed in all positions between the vertical and the horizontal. The horizontal position is sometimes necessary if photographs are to be taken by the microscope.

Many devices are available for changing the objective. It is essential that the objective is always brought before the lower end of the tube in such a way that the optic axis of the objective coincides with the optic axis of the rest of the system. The fittings of the objective and the changer are so arranged that little or no fine adjustment is necessary after the change. The most widely used is the revolving changer (fig. 60, Plate). The revolver may hold two, three or four objectives. In the sliding changer the objective is, dovetailed to a slide, the correct position being secured by clamps.

Fully equipped microscopes have apparatus for moving and turning the object. In simple microscopes the stage plate lies on the stand held by two springs, and must be moved by the hand (fig. 60, Plate). For elaborate work a so-called cross-table is indispensable. By means of screws the stage plate is movable in two directions at right angles to one another, in the plane of the stand. In many cases the stand is also movable round the optic axis.

The microscope stands described above can be used for the greater number of the naturalist's experiments. For very special objects the stand must be expressly made; thus stands with tube carriers very much projecting are made for examining sections of the brain. The petrographical microscope is shown in fig. 61, Plate.

In order to determine the refractive index when the thickness of the crystal is known, or the thickness of the crystal when the index is known, a fine adjustment A makes it possible to measure exactly the changes in the length of the microscope. Further, a revolving stage plate provided with a graduation B is used to determine the angle in crystals. To obviate mistakes the optical axis of the microscope must coincide with the revolving axis of the plate, and the revolving plate has a central position C to keep this condition fulfilled. In many stands the objective can be centred instead of the plate. For measuring this angle, an eyepiece with cross-threads is used. In the lower focal plane of the eyepiece, at the spot where the real image which the objective forms of the object arises, a glass plate is introduced on which are two fine cross lines or even two very thin threads. The eye-lens can be adjusted for the thread-plate, so that different observers can see the cross clearly. The cross is always adjusted first. When observing with such an eyepiece, care must be taken that the real image of the object lies in the plane of the cross-threads, *i.e.* that there is no parallax. The adjustment is easily controlled. If the eye is moved to and fro over the eyepiece and the image makes apparently similar movements in relation to the cross threads, then the image does not yet lie in the plane of the threads.

To measure the angle, the images of the crystal edges are covered in turn by one of the threads by turning the table, and the angle of rotation is read from the scale. A cross-table is very convenient for this calculation, for with the aid of the two movable slides situated in the plane of the plate and at right angles to one another, the point where the two crystal edges intersect can be quickly and correctly brought into the revolving axis of the plate. This measurement can also be made with a goniometer eyepiece, in which a row of parallel double-marks are used instead of the cross threads. The fitting of the eyepiece at the upper end of the tube is provided with a graduated circle. The eyepiece proper with the parallel strokes can be revolved, and the rotation be read from the graduated circle. In carrying out this calculation the marks of the thread-plate have only to be placed exactly parallel to the crystal edge.

For examining preparations in polarized light a polarizer D is introduced in the illuminating apparatus below the diaphragm and an analyser E above the eyepiece. The analyser can be rotated, the angle being read by a divided circle F. Very often the analyser is placed in the tube, a little above the objective: it is then generally in a case G, which can be put into the tube. The placing of the analyser near the objective has the advantage that the field of view is not restricted, as is the case if the analyser is used above the eyepiece. Nicols's, Glan-Thomson prisms or similar polarization apparatus are used as polarizers and analysers. Below the analyser G a plate H of selenite or mica may be put in the course of the rays. This small plate can also be laid above the polarizer in the illuminating apparatus or in the eyepiece.

To examine crystals, especially in converging light, a condenser, movable in the optic axis, is needed above the polarizer. The image produced by the microscope objective M in its back focus plane is then observed through a supplementary microscope. The objective of this supplementary microscope, the Bertrand lens, can be applied through a window I at the lower end of the inner tube K. By using a rack and pinion movement L the supplementary microscope can be adjusted for the images. There is nearly always an arrangement to observe the preparation first in convergent light and then in parallel polarized light. This change can often be brought about by taking away or adding parts of the condenser.

Micrometry

It is often required in microscopical work to determine the size of objects or parts of objects.

There are three essential ways of performing this. The first method uses the objective screw micrometer. The object is placed on a slide in the plane of the stage plate and able to be very finely moved by the micrometer screw, which has as fine a worm as possible. A divided cylinder is fixed to the turning knob, which thus makes it possible to measure fractions of the revolution. The revolutions of the cylinder are registered by a calculator. The use of an eyepiece with a cross thread is essential to this measurement. After the microscope has been so adjusted that the image of the object to be measured falls exactly in the plane of the cross threads, the object is moved by the micrometer until one edge of the object is exactly covered by a thread. The micrometer is now read. Then the object is moved by the micrometer till the image of the other edge is covered by the thread in the eyepiece, and the micrometer is again read. The difference between the two positions gives the size of the object. The objective screw micrometer is, however, not sufficiently delicate, and is only used when comparatively large objects are to be measured, and especially for objects whose edges do not appear at the same time in the field of view.

The second and most widely used method employs a micrometer eyepiece. In this case not the object itself but a real image which has already been magnified by the objective is measured, and obviously much more accurate results are possible. The most accurate calculations are obtained by using the screw micrometer ocular (fig. 54). Directly below the collective lens of a Ramsden eyepiece a slide *b* can be moved by a micrometer screw *a*; the slide carries a little glass plate *c* provided with a graduation. With the help of this scale the total revolutions of the screw can be read; fractions of the revolution can be read from the divided cylinder *d*. The scale is generally divided into hundredths of millimetres or thousandths of inches. A fixed mark which serves as an index is placed on the lower side of the collective lens and is seen clearly at the same time as the graduation of the movable slide. The micrometer stands at zero if the zero mark of the cylinder coincides with the index and the fixed mark is at a known division. The calculation is most convenient if the micrometer is left in the position of zero and the object is moved till one of its edges corresponds to the zero mark of the eyepiece scale. If the micrometer is then moved till another graduation corresponds to the other edge of the image the size of the image can be read off. As this method measures

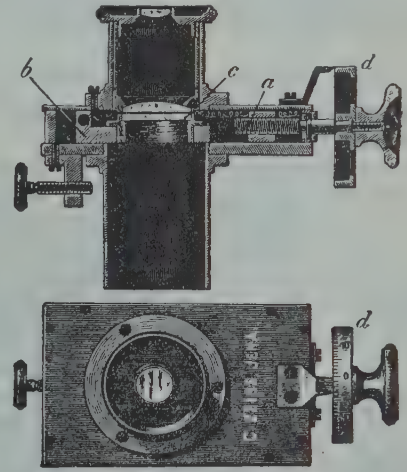

Fig. 54.—Screw Micrometer Ocular. Sectional elevation and plan (Zeiss).

the image correctly to a few thousandths of millimetres, the object itself is measured accurately to some hundred-thousandths of millimetres, if it has been magnified a hundred times by the objective. To keep up this degree of exactitude the magnification of the objective must be carefully ascertained, *e.g.* by using an objective micrometer. A fine scale with known intervals is put on the stage plate, and by determining the distance between the graduations of the objective micrometer formed through the same objective, by means of the screw micrometer ocular, the magnification of the objective is determined. As the errors in the graduation of the objective micrometer are also magnified, very exact scales are necessary. When determining the magnification the microscope must be used under exactly the same conditions: neither the length of the tube nor the focal length of the objective may be altered.

A fixed eyepiece micrometer is simpler and more popular. This consists of a scale on a little glass plate, which, instead of a cross wire, is placed in the eyepiece. The adjustment must be such that the image produced by the objective falls exactly in the plane of the scale. The size of the image is determined by calculating the entire interval taken up by it. By using an objective micrometer in place of the object, the magnification of the objective can be ascertained and from this the actual size of the object. As fractions of intervals can only be estimated in this method, a measurement with such an eyepiece scale can of course not be as exact as with a screw micrometer ocular. However, such a determination of size is often quite accurate enough.

A third method employs a drawing prism. The object and the drawing plane are seen at the same time and the outlines can be readily drawn. If, as before, an objective micrometer is placed below the microscope in the place of the object, and the size of a special micrometer-interval is drawn on the same board, then the actual size of the object can be ascertained. Instead of first drawing the object and the objective micrometer, they can of course be projected at the same moment on a scale on the drawing board.

The errors attending the determination of the size of a microscopic object depend chiefly on the accuracy of the objective micrometer; any errors in the micrometer being magnified by the objective. These may be diminished by using different parts of the objective micrometer for the correction of the eyepiece scale, and the calculation of the size is based on the found mean value. A second error can arise through the inaccuracy of the eyepiece micrometer, and also in the case of a screw micrometer through periodic faults of the screw, and through dead motion. The eyepiece micrometer allows its errors to be diminished, if one measures at different points and then fixes a mean value. The dead motion of a micrometer screw is best avoided by working the screw always from one and the same side. The thickness of the cross wire may also occasion a fault. For this reason there is sometimes employed two very narrow threads lying beside one another, and which limit the image as nearly as possible.

The Testing of the Microscope

The excellence of a microscope objective depends on its definition and its resolving power.

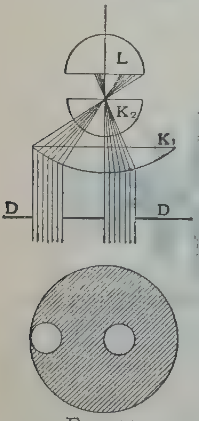

Fig. 55.
DD = diaphragm.
K_1K_2 = condenser.
L = front lens of the objective.
The lower figure shows the plan of the transmission.

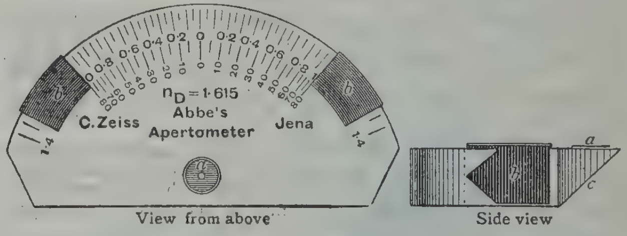
The definition is better according as the chromatic and spherical aberrations are removed; there always remains in even the best constructions some slight aberration. In consequence of these residual aberrations, every object-point is not reproduced in an ideal image-point, but as a small circle of aberration. These circles will be objectionable when the smallest details are examined. The size of these circles depends, in the case of equal tube lengths, only on the type of the objective, and not on the focal length, exact execution being assumed. Object details will only be well seen if the aberration circles are small in comparison. The size of these details in the image depends only on the magnification of the objective, $M = \Delta/f_1'$, and can by appropriate choice of the focal length of the objective be brought to the right value. In the case of a suitable ocular magnification, the details will be well seen, while the aberration circles remain invisible. It is therefore possible to judge the excellence of the focusing of objectives on the strength of the ocular-magnification, or the over-magnification, which they permit.

E. Abbe, through the so-called delicate ray transmission, suggested a way by which the quality of the images of objectives can be observed. The ray transmission, shown in fig. 55, is obtained by means of a stop of the form shown in the lower figure and placed under the condenser in the plane of the iris diaphragm. The entrance pupil is in this way reduced on two small separate fields, which nevertheless contain rays of all zones. It is necessary that the outside edge of the diaphragm coincides with the edge of the entrance pupil. This can be attained by drawing the iris diaphragm so far as to form the entrance pupil. The double diaphragm is then in such a position that the edge of the outer diaphragm coincides with the edge of the iris diaphragm.

The object employed must have distinct boundaries. Abbe's test plate consists of an object carrier on which six cover glasses of exactly determined thickness (between 0·09 mm. and 0·24 mm.) are cemented. The cover glasses are silvered on their under surfaces, and in the silvering fine lines are drawn; these lines form the test object. This plate admits at the same time of a correct determination of the thickness of the cover glass, for which the best correction exists. So long as the object is not sharply focused two separate dispersion figures will be seen. The defects of the objective are revealed, *e.g.* two adjacent sharp images are formed, which become indistinct if they coincide, or one pencil produces a distinct, the other an indistinct image, or that the images are surrounded with coloured rings. Owing to the curvature of the image, all parts of the object are not seen distinctly at one and the same time.

The resolving power of an objective depends on its numerical aperture. The numerical aperture can be determined in two ways. A diaphragm with a very narrow hole is placed on the stage, and the microscope sharply focused on the edges of the hole. The illuminating mirror is turned aside and a graduated scale is laid on the foot of the microscope. Strong systems produce in the proximity of their back focal plane an image of the scale, which can be inspected with a weak auxiliary microscope, and the length of the visible part of the graduation determined. The ratio of half the length of the visible piece of the scale to its distance from the edge of the diaphragm on the stage gives the tangent of half the angular aperture. The sine of this angle is the numerical aperture for dry lenses. With weak systems no auxiliary microscope is necessary, the eyepiece being removed and the scale viewed directly in the tube.

E. Abbe constructed a simple instrument for the determination of the aperture, termed the apertometer (fig. 56). A semi-circular glass plate bears two scales, over which two black thin metal plates bent back at right angles may be moved. A little hole in the silvered plate *a* marks the centre of this circle. Through this hole the points of the metal plates *b* can be observed by total reflection on the surface *c*. The apertometer is laid on the stage, so that the hole lies in the axis of the microscope, and the hole is sharply focused. The eyepiece being removed the image of the metal plates *b* produced by the objective is seen. In order to ensure for the eye a central position, there is fixed on the upper end of the tube in place of the eyepiece a disk of pasteboard or metal with an axial hole. The metal plates *b* are then moved till the points just cut off the edge of the field to be surveyed. The angular or numerical aperture can then be read off. With strong systems the vanishing of the points is observed with an auxiliary microscope, formed by means of the inner tube. In immersion systems the immersion liquid is placed between the front lens and apertometer.



View from above
Side view

Fig. 56.—Abbe's Apertometer (Zeiss).

If the numerical aperture be known the resolving power is easily found. The resolving power can also be determined by using different fine test objects. Norbert's test plates, which bear graduated groups of extremely fine and narrow divisions are very useful, while the tests of *Amphipleura pellucida* and *Surirella gemma* are often employed.

The magnification of a microscope is determined from the focal lengths of the two optical systems and the optical tube length, for $N = 250\ \Delta/f_1'f_2$. To determine the optical tube length Δ, it is necessary to know the position of the focal planes of the objective and of the ocular. If one focuses an auxiliary microscope, carried in the inner tube, on the image situated in the back focal plane of the objective of a distant object, and then on the dust particles lying on a slide pressed against the end of the outer tube, the displacement of the auxiliary microscope gives the distance of the back focal plane of the objective from the end of the outer tube. To determine the position of the anterior focal plane of the eyepiece, the eyepiece is placed on the stage with the eye-lens downwards. An auxiliary microscope is now focused first on the image of a distant object and then on the plane of the edge of the setting. This plane can be marked by a small piece of paper. This gives the distance of the anterior focal plane of the eyepiece from the bottom edge of the setting of the eyepiece and consequently also of the edge of the eyepiece carried by the upper end of the tube. These measurements determine the optical tube length Δ.

There are many methods for determining the focal length of the objective. The objective to be examined is placed on the stage, and in the manner just shown, the distance of the focal plane from the edge of the fittings or to the surface plane of the front lens is determined. Any plane object a few yards distant can be used. If the object can be seen by using the mirror, the plane mirror must be used; then the actual size of the object and of the image produced by the objective is measured (of the image by a micrometer ocular). The distance of the object from the nearer focus of the objective is next determined. This distance is composed of the distance of the object from the centre of the plane mirror, and of the distance of the focus of the objective on the stage plate from the centre of the plane mirror. Let the size of the object be y, the size of the image y' the distance of the object from the focus x, then $y/y'=x/f_1$ from which f_1 can be calculated (see LENS). The same method can be used to determine the focal length of the eyepiece. These are the dimensions necessary for determining the magnification of the microscope, viz. the optical length of the tube Δ, the focal lengths of the objective f_1'; and of the eyepiece f_2.

The focal length of an objective can be more simply determined by placing an objective micrometer on the stage and reproducing on a screen some yards away by the objective which is to be examined. If the size of the image of a known interval of the objective micrometer is determined by an ordinary scale, and the distance of the image from the focal plane of the objective belonging to it is measured, then the focal length can be calculated from the ratio $y/y'=f_1'/x_1'$, in which y is the size of the object, y' that of the image, and x_1' the distance of the image from the focal plane belonging to it.

Besides this indirect method of determining the magnification there is also a direct one, in which it is not necessary to first measure f_1, f_2 or Δ. If a drawing prism is used above the eyepiece, and an objective micrometer is inserted, then if a scale is laid on the drawing board which is 25 cm. distant from the exit pupil, one or more intervals of the objective micrometer can be seen projected on the scale lying on the board. The comparison of the two scales gives directly the magnification. The course of the light within the drawing prism must be taken into account when determining the distance of the scale from the exit pupil. Although this method does not give very accurate results, it is more convenient and simple than the indirect method.

Kaiser, *Technik des modernen Mikroskopes* (Vienna, 1906), deals with the practical aspects, whilst the theory is treated in M. von Rohr (*Die Theorie der optischen Instrumente*, Berlin, 1904) and in S. Czapski (*Grundzüge der Theorie der optischen Instrumente*, ed. by O. Eppenstein, Leipzig, 1904). (O. HR.)

MICROTOMY (Gr. τόμη; τέμνειν, to cut), the term applied to the preparation of minute sections of organic tissue for the microscope. In 1875 the methods were yet in their infancy; their development has enabled observers to achieve the most exact study of minute anatomy, in the case of small objects, which without these methods could only be investigated by the unsatisfactory process of focusing with the microscope through the solid object.

It is not necessary here to detail at length the *wet method* of preparing sections. Briefly, the tissue is soaked in a solution of gum, or of gum and syrup, and after being frozen by ether spray, or by a mixture of ice and salt, is cut into sections either by the Rutherford, Cathcart or some similar section-cutter, or by apparatus which can be fitted to the more modern types of microtome referred to below. This method, which is to-day used mainly by pathologists, has two main disadvantages: the prolonged action of watery fluids on the tissues, and the impossibility of getting ribbons, each section having to be picked up separately.

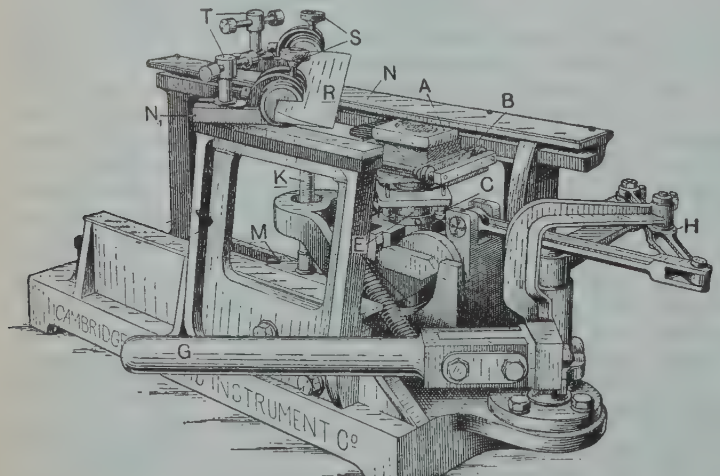
The general processes of the *dry method* employed in zoological and botanical microtomy are, up to a certain point, practically identified with those used for the preservation of animals and their tissues for other branches of microscopic work. In the first place the tissues must be *killed*; in the second, they must be *fixed*, *i.e.* the protoplasm must be set or coagulated as far as possible in the condition in which it appears in life; and in the third, they must be *hardened*, *i.e.* in most cases dehydrated. Killing may be effected by asphyxiation or narcotization (nicotine, cocaine, chloral hydrate, &c.) in special cases, but is generally achieved by fixing reagents, of which corrosive sublimate and other chlorides, picric, acetic, osmic and chromic acids, alone or in combination, chromates and strong alcohol are the most usual. These serve to a great extent also as hardening agents, but alcohol, used after them, completes this process effectively, and when not too strong (70%) is the best storage fluid. The second set of processes relates to the *staining*, without which transparent sections are almost invisible. The stains are divisible into *general* stains, which dye the tissue practically uniformly and indifferently; and *selective* stains, which have affinity for special tissues or cell elements. Of the latter group some fasten on nuclei, others only on the chromatin of the nuclei; some on connective tissues, others on muscle fibres and so on. It is probable that the action of all these selective stains is produced by definite chemical combination with compounds originally present in, generated in, or introduced into the tissue selected. The most generally useful stains for ordinary work belong either to the *cochineal* series (borax-carmine, carmalum, &c.), or to the *logwood* series (haematoxylin, haemalum, iron haematoxylin, &c.); in both of these great improvements have been introduced of late years by Dr Paul Mayer. The activity of these stains apparently depends upon the presence of alumina or of some similar base. For more special researches, such as cytology, neuropathology, neurohistology, and so forth, greater dependence is placed on the *coal-tar* colours, the name of which is legion. Some of these, such as safranine or gentian violet, are regressive stains; that is to say, the tissues are overstained uniformly, and the superfluous colouring matter washed out either by alcohol or by weak hydrochloric acid from the unselected parts. Others, such as methyl green, are progressive—that is, the colour is brought up to the pitch required and the reaction promptly stopped. The coal-tar stains can be used singly, or in combinations of two or three. Some of the best, unfortunately, are not permanent. A third group of stains is furnished by such reagents as silver nitrate, gold chloride, and the like (impregnation stains), which can be made not only to stain, but also to deposit a fine metallic precipitate on certain structures. In the case of small and delicate objects, the staining is done in the mass before any further preparation for sections, but with larger animals, or large pieces of resistant tissue, the stain is applied to the sections only. The processes so far mentioned are applicable to many branches of microscopic work.

When preparing tissues for sections the first step is complete dehydration, generally effected by bringing the object into absolute alcohol. It is then transferred to one of a group of reagents, which are miscible with absolute alcohol, but would form an emulsion with water, and are solvents of the embedding medium. The embedding mass in most general use is paraffin wax, melting at a temperature of 54° to 60° C., according to the character of the object and the thickness of section required. The object is transferred from absolute alcohol to benzol, chloroform, cedar oil, or similar fluid to the melted paraffin; the fluid diffuses and evaporates, leaving the tissues to be completely permeated by the paraffin. This process can be greatly hastened by the use of a partial vacuum. When impregnation is complete the paraffin is cooled rapidly, so as to assume a homogeneous non-crystalline condition, and the tissue thus comes to form part of a block of soft but tenacious material, which protects it from damage by air or damp, and can be readily cut by a razor. The block is then trimmed to the form of a triangle or rectangle, and fixed by a clamp or by local melting in the holder of the microtome.

The first automatic microtome suitable for cutting a block of tissue into a continuous series of sections was made in 1883 in the university workshops of Cambridge, from a design by W. H. Caldwell and R. Threlfall. Only a single machine was made, but in 1884 twelve machines were made by the Cambridge Scientific Instrument Company from a design by Caldwell. Since then numerous excellent and simpler forms of microtome have been evolved. Some of these have distinct advantages over others, but with microtomes as with other tools—the success of the results depends very largely on the manipulator, for every one works best with his accustomed instrument. In one type of microtome the razor is attached at one end only to a heavy block, sliding backwards and forwards in a horizontal V-groove; the paraffin block is fed to this either up a vertical guide (Schanze, Reichert, &c.) or up an inclined plane (Thoma-Jung). In another type the razor is firmly clamped at both ends, to diminish vibration, and the paraffin block advances to it at the end of a long lever on trunnion bearings (Cambridge rocker) or up a vertical guide (Minot types).

In the selection of a microtome, apart from its steadiness, rigidity, accuracy of workmanship, and so forth, it must be borne in mind that, in general, simplicity of working parts means longer life, and that an elaborate "automatic" mechanism, by which a single movement is translated into several in different directions, not only complicates the machine, but robs the operator of those alterations of pace, rigidity, pressure, &c., which are often necessitated by the varying texture in different parts of the object cut. For general use by less skilful students in a laboratory, price, simplicity and rapidity of work recommend the rocking microtome of the Cambridge Scientific Instrument Company, but it tends to fail at large or hard objects. For the all-round work of an investigator, its simplicity and finish have made Jung's sliding microtome with the Naples improvements deservedly popular for many years; it can be fitted with special apparatus for cutting celloidin and frozen objects, and it can be relied upon to cut any tissue, however difficult; but it cannot be worked as rapidly as some others, nor produce long ribbons of large objects. For this latter purpose the Minot-Becker, Minot-Zimmermann and Reinhold-Gilltay have been strongly recommended; these, however, are all of more complicated construction, with corresponding liability to uneven wear and damage; they are highly "automatic," leaving nothing but pace under control of the operator, and they are (particularly the last) expensive.

[In 1910 the Cambridge Scientific Instrument Company issued a new microtome designed primarily for cutting larger sections than was possible in their earlier forms, which respectively dealt with sections 12×20 mm. and 30 mm. in diameter; the new instrument cuts sections measuring 150×120 mm. (6×4⅜ in.) embedded in paraffin or celloidin and of a thickness varying from 0·002 to 0·06 mm., each division of the scale being equal to 0·002 mm. and the total distance of automatic feed being 21 mm. The construction and action of the instrument can be understood by referring to the figure; a detailed description is given, since the same principles are utilized to a greater or less extent in all sliding microtomes.



Large Sliding Microtome.

The object to be cut, having been embedded in a suitable preparation A, is fixed to a wooden block which is attached by clamps to the object-holder B. The object-holder is provided with mechanism by means of which the height of the block is determined; this is effected by mounting the holder in a cup-shaped socket at the extremity of a brass pillar E, which can be raised or lowered and fixed in any position by a clamp. In addition, the direction in which a section is cut can be varied by adjusting the four screws, one of which is shown at C, which orientate the block. The object-holder and feeding mechanism are carried on a sliding carriage which rests at three points on two guides in the frame N, N_1 of the instrument; and in order to secure easy running the necessary lubrication of the bearing surfaces is provided for by a groove in which oil is placed. The motion of the carriage in either direction is effected by the handle G, connected to a system of levers H, which, being constructed on geometrical principles, prevent any side-play and ensure a uniform motion. The arrangement for determining the thickness of the section cut consists of a stop-pin, which, operating through the ratchet M, causes a toothed wheel to revolve, which in turn raises the pillar K; the amount of the motion can be read off by an index. On the return stroke of the sliding carriage the stop-pin is again actuated in such a manner that just before the knife R reaches the object-holder the mechanism depresses this part of the instrument so that the knife is not fouled; and after its passage the object-holder is raised to the position appropriate for taking the next section. The knife R is rigidly set in two heavy brass clamps adjustable by the screws S, and these clamps are attached to the frame of the instrument by the screws T. The angle which the cutting edge makes with the frame is also adjustable, and by means of a small angular scale engraved on the knife-holders any setting can be easily determined or repeated. The knife is flat on one side and hollow-ground on the other. In using the microtome it is essential that the cutting edge of the knife points towards the end of the instrument where the handle is placed; the hollow-ground face should be uppermost, and the flat surface should not be exactly horizontal but slightly inclined so that the lower facet of the cutting edge is parallel to the frame. As to the relation of the position of the knife to the direction of motion, it is the usual practice, when paraffin sections are to be taken, to have the cutting edge at right angles to the motion; when, on the other hand, celloidin preparations are being cut, the knife must be set obliquely across the frame, an angle of 30° being convenient. This oblique setting is also recommended for paraffin sections. In addition it must be remembered that celloidin preparations always require lubricating when being cut, and it is also necessary to keep both the knife and the preparation constantly moistened with either 80% alcohol or with cedar-wood oil.]

The sections, when cut by the microtome with the knife straight and the two sides of the rectangular paraffin block parallel to it, in most cases can be got off in a continuous ribbon, each sticking to its predecessor. This very desirable result generally can be insured by a coating of softer paraffin; but if the object be large, or brittle, or of varying texture, it is safer to cut the sections singly from a triangular block with an oblique knife. The sections or ribbon are often not quite flat, but rolled, creased or compressed; they must be flattened before being attached to the slide. It is possible to carry out these two processes simultaneously by covering the carefully cleaned slide with plenty of a very dilute solution of Mayer's glycerine and albumen, and laying the sections on the fluid and the slide on a hot-plate; as the water becomes warm the sections flatten out, and as it evaporates they settle down on the slide, and are held there by the albumen (many other methods are in use). The slide is then warmed to melt the paraffin, and plunged into benzol, or some similar fluid, which removes the paraffin; thence into absolute alcohol, which dehydrates and coagulates the albumen. If the tissue has not been stained *en bloc* the sections can now be stained on the slide. After staining they are fully dehydrated, rendered transparent by oil of cloves, and mounted in xylol-dammar or Canada balsam. W. Giesbrecht was the first to fix sections on the slide, using a solution of shellac in creasote in 1881; and also in the same year and in the laboratory of the Naples aquarium, W. H. Caldwell first cut and fixed ribbons of sections.

For ordinary work the paraffin method excels all others for rapidity, certainty and cleanliness; but for large and hard objects, or crumbling tissues (such as ova with a large quantity of yolk), some manipulators prefer to embed in celloidin. By this method, after dehydration, the tissue is soaked in a mixture of absolute alcohol and ether; thence transferred either to increasingly strong solutions of celloidin in the same mixture or to a thin solution which is then boiled down till strong. The celloidin mass is then hardened: at first, if necessary, by drying; afterwards by a bath of chloroform or its vapour. It can then be cut in the microtome, either wet, or (if previously cleaned with cedar oil) dry like a paraffin block. The method is more tedious and more messy than the paraffin process; but amongst its advantages must be reckoned that little or no heat is required, and that the embedding mass is transparent, though it does not allow of such thin sections as paraffin.

The above accounts present an outline of the complex processes employed to-day, by which, on the one hand, sections 30 μ in thickness may be made through the entire human brain; and, on the other, organisms invisible to the naked eye may be cut into a long ribbon of consecutive sections 1 μ (one-thousandth of a millimetre) thick, every minutest fragment being retained in its proper place.

The standard book on the subject is Bolles Lee's *Microtomist's vade-mecum*. Other works are G. Mann, *Methods and Theory of Physiological Histology* (Oxford, 1902), and A. Flatters, *Methods in Microscopical Research* (London, 1905). (G. H. Fo.)

MIDAS, the name of several Phrygian kings. The first of these was said to have been the son of Gordius and Cybele, whose first priest he was, and in whose honour he founded a temple at Pessinus. Having taken the drunken Silenus back to his youthful charge Dionysus, he was rewarded by the god with the power of transforming everything he touched into gold. Finding himself in danger of starvation, even his food and drink being changed by his touch, Midas entreated Dionysus to take back the gift. By the command of the god he bathed in the river Pactolus, which henceforth became auriferous (Ovid, *Metam.* xi. 85–145; Hyginus, *Fab.* 191). Another story connects him with the musical contest between Apollo and Marsyas (or Pan). Having decided against the god, his ears were changed into those of an ass. He concealed them under a Phrygian cap; but the secret was discovered by his barber, who, being unable to keep it, dug a hole in the ground and whispered into it "Midas has the ears of an ass." He then filled up the hole, thinking his secret safe; but the reeds which grew up over the spot proclaimed it to all the world. Midas with the ass's ears was a frequent subject of the Attic satyr-drama. There is no doubt that Midas was the name of one or more real persons around whom religious legends have grown up. The name "Midas the king" occurs on a very ancient tomb in the valley of the Sangarius, the legendary seat of the Phrygian kingdom. The Phrygian monarchy was destroyed by the Cimmerians about 670 B.C., and the name Midas became in Greek tradition the representative of this ancient dynasty.

On the connexion between Midas and the Attic story see J. G. Frazer, *The Golden Bough*, ii. 134.

MIDDELBURG, the ancient capital of the province of Zeeland, Holland, in the middle of the island of Walcheren, 4 m. by rail N. by E. of Flushing, with which it is also connected by steam tramway and by ship canal (1873), which continues to Veere on the N.E. coast, with a branch eastward to Arnemuiden. Pop. (1903), 19,002. Middelburg contains many splendid old houses, which recall the prosperity which distinguished it until the end of the 18th century. The beautiful town-hall, built by Anton Keldermans about 1512, with a square tower 180 ft. high, and a façade adorned with statues of the counts and countesses of Zeeland and Holland, contains the valuable city archives and antiquarian and historical collections. The old abbey of St Nicholas, founded in 1150, and now occupied by the provincial council, has some fine old tapestry of the end of the 16th century. The building was added to in the 14th and 15th centuries, and partly rebuilt after a fire in 1492. It was the scene in 1505 of a meeting of the knights of the Golden Fleece, and was frequently the residence of royal visitors, including Maximilian, Philip the Fair and Charles V. The abbot of Middelburg formerly possessed a vote of his own in the Provincial States. What was formerly the nave of the abbey church is now the New Church, and the ancient choir constitutes the Choir Church. These churches are interesting for the monuments of William II., count of Holland, king of the Romans (d. 1256), the 16th century scholar Hadrian Junius, and Jan Pieterszoon; and the tombs of Jan and Cornelius Evertsen, who fell in the naval war against England in 1666. The high tower (280 ft.), known as *de lange Jan*, standing apart from the church contains a good chime of bells. The corn exchange, the hof St Joris and the hof St Sebastian (formerly buildings belonging to the gilds of archers, and now places of amusement) also deserve mention. The museum of antiquities belonging to the Zeeland Society of Arts and Sciences (founded at Flushing in 1769, and transferred to Middelburg in 1801) contains a complete collection of the fauna and flora of the province, many maps, plans and drawings relating to Zeeland, the first telescope made by Hans Lippershey and Zacharias Jansen in Middelburg in 1608, and some provincial Roman antiquities.

The extensive trade which Middelburg formerly carried on with the East and West Indies and with England and Flanders, was ruined by the war with England and the French occupation. But the construction of the railway in 1872, followed by the opening of the ship canal and the large dock (1876), as well as the establishment, by the aid of the chamber of commerce, of certain manufacturing industries (iron, machinery, furniture, oil and cigars), lifted it out of its isolation.

MIDDELBURG, a town of the Transvaal, 98 m. E. by rail of Pretoria, and 251 m. W. of Lourenço Marques. Pop. (1904), 5085—of whom 2343 were whites. It is prettily situated on the high veld, 5090 ft. above the sea, on one of the head streams of the Olifants River. Middelburg is the chief town of an administrative division of the same name, and is a trading centre for a large district. It is also the centre of one of the richest coalfields in South Africa. From some of the adjacent collieries excellent steam coal is obtained. Copper and cobalt are found in the neighbourhood.

Middelburg was chosen in 1901 as the place of conference for peace negotiations between the British and the Boers. After the occupation of Pretoria in June 1900 by Lord Roberts the Boer forces had been reduced to guerilla warfare, and Lord Kitchener, learning that the Transvaal commandants were despondent, invited General Botha to enter into negotiations, on the basis of the recognition of British sovereignty. The conference between Lord Kitchener and General Botha was opened on the 28th of February and the negotiations, which ended in failure, were protracted until the 16th of March (see TRANSVAAL: *History*, § *The War of 1899–1902*).

Middelburg is also the name of a town in the Cape Province, South Africa, 250 m. N. by W. of Port Elizabeth. Pop. (1904), 6137.

MIDDLE AGES, THE. This name is commonly given to that period of European history which lies between what are known as ancient and modern times, and which has generally been considered as extending from about the middle of the 5th to about the middle of the 15th centuries. The two dates adopted in old textbooks were 476 and 1453, from the setting aside of the last emperor in the West until the fall of Constantinople. In reality it is impossible to assign any exact dates for the opening and close of such a period. The trend of recent historical research leads one even to doubt the validity of the very conception of any definite medieval period. The evolution of modern European society has been continuous. Progress has not been uniform. There was much retrogression with the intrusion of new barbarian races; but from their absorption by the 10th century until the 20th there is not a century in which some notable gain was not made towards the attainments of modern civilization. The correct perspective places between the summits of modern and ancient times, not a long level stretch of a thousand years, with mankind stationary, spell-bound under the authority of the Church, absorbed in war or monastic dreams, but a downward and then a long upward slope, on both of which the forces which make for civilization may be seen at work.

It is clear that a survey of the history of these so-called middle ages—long use makes the term inevitable—must include not only the political phase, but also economics, religion, law, science, literature, &c., since all are involved in the concept. A hurried outline of each of these vital branches of our civilization will at once reveal the falseness of the usual periodizing. It is only after having traced these one by one that we can properly review the process as a whole.

In political history, the epochal fact which marks the close of ancient times is the decline of the Roman Empire. This was a process extending over three or four centuries, in which no one date lends itself to the historian. The deposition of Romulus Augustulus, the last Roman emperor in the West, in 476, was certainly not one of those events upon which the history of the Western world depends. Outwardly it did not mark the end of the Empire, but the restoration of imperial unity. The throne in Italy had been vacant before, and the restoration of unity was realized in fact under Justinian. There is no reason why the date 476 should stand out in European history more strongly than half a dozen other such dates. Yet we may say that the 5th century did witness the actual dismemberment of the Roman Empire. The new nations in Spain, Gaul, parts of Italy and Britain were forming the rude beginnings of what were to become national states in the centuries following. Western Europe was taken out of the imperial mould and broken up. This is a revolution of sufficient magnitude to be regarded as politically the opening of a new era. It had been long preparing in the economic and administrative decline of the Empire, and in the steady influx of Germanic peoples into Roman territory for over two centuries; but the power of the old civilization to absorb the new races was exhausted by the 5th century, and the political history of Europe was turned into a different path. That path, however, was not destined to end blindly in a "middle age." The line of political development marked out in the 5th century—that of the national state—still continues. The revolution in which Alaric, Theodoric and Clovis figured did not set the problem for the middle ages only, as is frequently stated; its full meaning did not appear until the Peninsular War, the Prussia of Stein and Scharnhorst, and even Solferino and Sedan. Thus the 5th century politically introduces not so much the history of the middle ages as that of modern Europe.

The immediate introduction, however, was a long one—so long and so distinct from the later development as to constitute in itself a distinct phase. For five or six centuries—from the 5th until about the 11th—comparatively little permanent progress was made. The Germanic tribes were still adjusting themselves and slowly learning to combine their primitive institutions with the remains of those of Rome; the premature union under Charlemagne gave way before new invasions, and anarchy became crystallized in feudalism. It was not until the 12th and 13th centuries that modern national states really took shape: England with its trial by jury, circuit courts, Magna Charta and parliament; France under the strong hand of the Capetians. A political middle age certainly lay between Theodosius and William the Conqueror, or at least between Justinian and Henry II. It is difficult to grasp its vastness. Few students of history realize that the period from the Saxon to the Norman Conquest of England would take us as far back as from George V. to Edward I.; or that from Theodosius to Philip Augustus there is an interval equal to that between the accession of Hugh Capet and the French Revolution.

This, however, is not the period most frequently termed the middle ages in political histories. It does not include those two institutions which more than any others stand in popular imagination as genuinely medieval—the papal monarchy and the Holy Roman Empire. The papacy received its full monarchial structure under Hildebrand (Gregory VII.) in the middle of the 11th century; its political decline set in suddenly after the pontificate of Boniface VIII. at the opening of the 14th. The great age of the Empire began slightly earlier, and continued until the fall of the Hohenstaufen in the middle of the 13th century. One cannot now deny the term middle ages to the period of these two institutions. It has been consecrated to this use too long. Yet when we include under a common name two eras so distinct as this and that preceding, our term becomes so vague as to be almost valueless. Moreover, it is doubtful if this second period is really as "medieval" as it has seemed. Papal monarchy and Holy Roman Empire were not the only political phenomena of their age, and it is possible that their vast pretensions have somewhat blinded historians as to their real importance. While they were struggling to enforce their claims to universal sovereignty, the royal power, less extravagant but more real, was welding together the feudal states of France and moulding the England of to-day. Compared with this obscure process—this spread of the king's peace along the highways and through the distant forest lands of the 12th and 13th centuries—papal interdicts and jubilees, however impressive their spectacle, are but fleeting shows. The chivalry of Germany pouring through Alpine passes for an Italian campaign, or a coronation, left little trace in history except the lesson of their futility. There is much in the imperial and papal histories that is merely spectacular and romantic; much that appeals to the imagination and lends itself to myth; and since the sources are abundant—the papal archives inexhaustible and the German chronicles easily accessible—an undue emphasis has been placed upon them. It is at least evident that the political middle ages were already disintegrating during the period of papal monarchy and Holy Roman Empire.

In economic history there is a more definite line traceable. The one great economic change brought about by the decline of the Roman Empire was the lessening of urban life throughout the greater part of Europe, the closing up of avenues of communication and the predominance of isolated agricultural communities. This phase began to give way in the 11th century to a commercial and industrial renaissance, which received a great impetus from the crusading movements—themselves largely economic—and by the 14th century had made the Netherlands the factory of Europe, the Rhine a vast artery of trade, and north Italy a hive of busy cities. The discovery of America and the expansion of commerce merely readjusted conditions already highly developed. The period of isolated economy which we may term medieval lasted only from about the 5th to the 12th centuries. As for manufactures, the antique methods survived until the 18th and 19th centuries.

In religious history—to be distinguished from that of the political organization referred to above as the papal monarchy—the official recognition of the Christian Church by Galerius in 311 serves as a convenient starting-point for what we know as universal Christendom, though the slow disappearance of paganism, as distinct from Christianity, stretches over at least a century more. The Reformation of the 16th century has long been regarded as the close of the period. The real close, however, is the present day—as the result of the rationalism and science of the 18th and 19th centuries. The heroes of the Reformation, judged by modern standards, were reactionaries. Unconsciously and to its own ultimate damage the Reformation forged the weapons of progress; but it was itself in no sense, except the institutional and political, the end of that religious history inaugurated before the Council of Nicaea. The real change in attitude which marks the dawn of a new era came in the generation of Voltaire. And "medievalism" is only now on the defence against "modernism," both Catholic and Protestant.

In legal history there was a distinct medieval period, when Germanic customs superseded Roman law, that most splendid of Rome's legacies. But the renaissance of law began relatively early; by the 12th century it had created a university, by the 13th it was helping to organize national states and laying the basis for that order which the economic renaissance was already demanding.

In science there was no great product in antiquity to be lost. Compared with art or law, literature or philosophy, ancient science (in our sense) was almost insignificant. The promise in Aristotle of such production remained unfulfilled. The 17th century is not so much a renaissance here as a mere beginning. No one can deny the general unscientific, uncritical nature of "medieval" thought. A single Roger Bacon does not relieve his age of the charge. But the middle age in science must include much of antiquity, including Pliny.

Philosophy was the one subject which had, clearly and definitely, a medieval period. Scholasticism, which absorbed the attention of most thinkers from about the 11th to about the

15th centuries, is so easily marked off and played so considerable a rôle in the academic history of that time, that historians often refer to it as the only intellectual interest of "medieval" men. Then, selecting some of the later and less virile scholastics as victims, they ask how men could be seriously interested in their trivialities. But these men were not all busy over the problem of how many angels could stand on a needle-point; nor were they all dominated by the religious spirit of faith or intellectual cowardice. They were searching for truth with scientific eagerness. Their very failure made possible the modern era. It is perhaps unnecessary to point out how small a proportion of the "intellectuals" were scholastics even in the 13th century.

In the realm of art the "middle ages" had already set in before Constantine robbed the arch of Titus to decorate his own, and before those museums of antiquity, the temples, were plundered by Christian mobs. The victory of Christianity—iconoclastic in its primitive spirit—was but a single chapter in the story of decline. The process was completed by the misery of the decaying empire, and by the Germanic invasions. The barbarians, however, destroyed less than has been commonly supposed. Destruction was more the product of necessity than of wantonness. Thus public monuments became fortresses, and antique sculpture was built into city walls. Such art as continued was almost wholly religious; for in the wilderness of the times the churches formed oases of comparative prosperity and peace, and, even in the darkest times, wherever such oases existed there the seeds of art took root. The Church architecture of the "middle ages," then developed naturally and without a break, through the Byzantine and Romanesque styles, out of the secular and religious architecture of Greece and Rome. And, with the return of comparatively settled and prosperous conditions, not only architecture but the other arts also blossomed under the influence of what was later stigmatized as the "Gothic" spirit into new and original forms. Down to the Reformation the churches continued to be, as the temples of the ancient world had been, the main centres of the arts; yet the arts were not confined to them, but flourished wherever, as in castles or walled cities, the conditions essential to their development existed. With the revival of civilized conditions in secular life, secular ideals in art also revived; the ecclesiastical traditions in painting and sculpture, which always tend to become stereotyped, began in the West to be encroached upon long before the period of the "Renaissance." The 12th and 13th centuries, which witnessed the great struggle between the secular and spiritual powers in the state, witnessed also the rise of a literature inspired by the lay spirit, and of an art which was already escaping from the thraldom of the stereotyped ecclesiastical forms. Gothic sculpture was not incidentally decorative, it was an essential element in the harmony of the architectural design. The elongated kings that guard the door of Chartres Cathedral, or the portals with the Last Judgment, are a necessary element in the façade. Thus fettered, even the realism of the Gothic sculptors failed, except in rare instances, of its full expression. The plastic arts were left for Italy, where antique models were at hand, and the glory of its achievement in the 15th and 16th centuries was so great as to obscure in men's eyes what had been done before.

But this Italian renaissance was not the only one. It was but one of many; and it was concerned with the two subjects which perhaps least deeply influence the lives of the mass of men—literary humanism and art. It is obviously absurd, in the face of the foregoing facts, to regard it as the end of a middle age in anything but in its own field.

When one studies the history of Europe subject by subject, as indicated above, and not merely in a monastic chronicle of things in general, chosen according to the author's point of view, one sees the old-time framework passing away. The traditional idea of a barren middle age and a single glorious renaissance proves false. An organic study of the past reveals a more rational picture of the process which produced the Europe of to-day. Cataclysm and special creation here as elsewhere give way to evolution. The new synthesis reveals a universal decline from the 5th to the 10th centuries, while the Germanic races were learning the rudiments of culture, a decline that was deepened by each succeeding wave of migration, each tribal war of Franks or Saxons, and reached its climax in the disorders of the 9th and 10th centuries when the half-formed civilization of Christendom was forced to face the migration of the Northmen by sea, the raids of the Saracen upon the south and the onslaught of Hungarians and Slavs upon the east. That was the dark age. It left Europe bristling with feudal castles, and already alert for the march of progress. At once the march begins. Henry the Fowler beats back the Slavs and places the outposts of Christendom along the Elbe and the Oder. Otto I., his son, drives the Magyars from southern Germany and establishes the East Mark (Austria) to guard the upper Danube. The restoration of the Empire in 962 marks the first milestone on the pathway of recovery. Already scholarship had found a home in monasteries planted in the heart of the German forests. The succeeding century brought the Empire to the acme of its power, until Henry III. in the Synod of Sutri, sat in judgment on the impotent and demoralized papacy. Meanwhile France had been learning something even in its feudal anarchy. The monks of Cluny were at work. The Capetians had begun. The great monastery of Bec was drawing the sons of northern sea-robbers to the service of that greatest civilizing force, the Church. The progress made through even this darkest age may be measured by the difference between the army of Rollo and that which William the Conqueror gathered for the invasion of England.

There is a legend, current among historians from the days of Robertson and Hallam, that as the year 1000 approached mankind prepared for the Last Judgment; that the earth "clothed itself with the white mantle of churches," and like a penitent watched in terror and in prayer for the fatal dawn. Contemporary sources fail to bear out this beautiful conception. Apart from the fact that reckoning from the birth of Christ was by no means universal, and consequently the mass of men were ignorant that there was such a thing as the year 1000, one wonders how that most enduring type of architecture, the Romanesque, reached its maturity among men who thought that the earth itself was so soon to "shrivel like a parched scroll." Recent scholarship has absolutely disproved this legend, founded on a few trite phrases in monastic chronicles, and still to be heard in similar contexts. The year 1000 marks no epoch in medieval history.

The latter half of the 11th century witnessed the most remarkable political creation in Europe since the days of Caesar, the papal monarchy of Hildebrand. The great scholastic controversies had already begun in the schools of France; the revival of Roman law had called forth the university of Bologna, and the canonists had begun the codification of the law of the Church. The way was already cleared for the busy 12th century—the age of Louis VI. and Henry II., of Glanvill and Suger, of Abelard and Maimonides, of Frederick Barbarossa and Alexander III., of the emancipation of French communes and cities and the independence of those of Lombardy, of the growth of gilds and the extension of commerce, of trouvère and troubadour and the beginnings of vernacular literature, of the creation of Gothic art, of trial by jury and the supremacy of royal justice. Such are but a fraction of its achievements. The 12th century stands beside the 18th as one of the greatest creative centuries in human history. The 13th like the 19th applied these creations in the transformation of society. The century of Dante was also that of the first English parliament; its vast economic expansion enabled the national state to triumph in both England and France, and furnished the grounds for the overthrow of Boniface VIII. Into the complex history of this momentous age it is impossible to go in any detail. Sufficient to say that in the opening quarter of the 14th century England and France at least stood on the brink of "modern times." Then these two nations entered upon that long tragedy of the Hundred Years' War, a calamity absolutely immeasurable to both. But during its massacres, jacqueries, plagues and famines, the cities of Italy, growing rich with trade and manufactures, were in their turn the centres of progress, this time in a new direction, toward the recovery of the antique past and the development of art.

This is the so-called Renaissance (*q.v.*). The humanists which it produced, interested only in its splendid revelations, forgot or ignored the achievements of the period which intervened between Cicero and Petrarch. Then by the genius of their work they fastened their mistaken perspective upon historians and the cultured world at large. They struck upon the unfortunate and opprobrious term "middle ages" for that which stood between them and their classic ideals. The term was first used in this sense by Flavio Biondo, whose "decades" was an attempt to block out the annals of history from 410 to 1410. His treatment fell in admirably with the ideas of his age and of that following. To Protestants the age of the papal monarchy was like the reign of Anti-Christ. Then, after the indifference of humanists and Protestant polemic, came the disgust of men of science at the scholastic philosophy—an attitude best exhibited in Bacon's *Advancement of Learning*. The 18th century was thus trebly barred from a knowledge of genuine medieval history. Romanticism, that reaction in which Sir Walter Scott, the Schlegels and Victor Hugo so largely figured, was as far from understanding what it admired as classicism had been from what it hated. Its extravagant praise of all that savoured of the middle ages was still blind to their real progress and work. They were, for it, the ages of romance and chivalry. The view of the romanticists was as one-sided as any that had gone before. It is only with the introduction of a wider outlook in the scientific study of history that it has been possible to straighten the perspective and modify the traditional scheme.

In the purely intellectual sphere it is certainly true that the recovery of the antique world was of great importance; that it made possible genuine criticism by presenting new points of contrast and opening up fields that led away from theological quibbles. But it did not mean the "double discovery of the outer and inner world." Mankind did not, as Burckhardt and J. A. Symonds lead one to imagine, suddenly throw off a cowl that has blinded the eyes for a thousand years to the beauty of the world around, and awaken all at once to the mere joy of living. If any one was ever awake to the joys of living it was the minnesinger, troubadour or goliard, and the world had to wait until Rousseau and Burns before its external beauty was discovered, or at least deeply appreciated, by any but a few Dutch artists. Even Goethe crossed the Alps with his carriage shutters closed. Mont Blanc is not mentioned by travellers until after the middle of the 18th century. The discovery of the outer world is a recent thing in art as well as in science. As for the claim that the "Renaissance" delivered men from that blind reliance upon authority which was typical of "medieval" thought, that is a fallacy cherished by those who themselves rely upon the authority of historians, blind to the most ordinary processes of thought. In this regard, indeed, in spite of the advance of scientific method and the wealth of material upon which to base criticism, we are still for the most part in the middle ages. The respect for anything in books, the dogma of journalistic inerrancy which still numbers its devotees by millions, the common acceptance of even scientific conceptions upon the dicta of a small group of investigators, these are but a few of the signs of the persistence of what is surely not a medieval but a universal trait. The so-called Renaissance did much; but it did not do the things attributed to it by those who see the "middle ages" through humanist glasses.

Upon the whole, therefore, it would seem that not only was there no one middle age common to all branches of human evolution, except the period more definitely marked as the dark age, but that those characteristics which are generally regarded as "medieval" were by no means limited to a single epoch of European history. In short, the dark age was a reality; but the traditional "middle ages" are a myth. (J. T. S.*)

MIDDLEBORO, a township of Plymouth county, Massachusetts, U.S.A., in the S.E. part of the state, bounded on the N.W. by the Taunton river. Pop. (1890), 6065; (1900), 6885—of whom 920 were foreign-born; (1910 census) 8214. Area, about 70 sq. m. The principal village also is named Middleboro; it is 35 m. S. of Boston, is served by the New York, New Haven & Hartford railroad and by electric lines connecting with Taunton, Boston, New Bedford and Cape Cod, and has a town-house, a soldiers' monument, and a public library housed in a building erected from a fund (part of which is used as a permanent endowment) bequeathed by Thomas Sprout Peirce (1823–1901), a merchant of the township, who, in addition, bequeathed about $500,000 as a special trust-fund for the use and benefit of the town of Middleboro; the income has been spent largely in the construction of macadam roads, the erection of an almshouse and the installation of special courses in the high school. The village, a place of considerable natural beauty, is a summer resort, and has various manufactures. Other villages in the township are North, East and South Middleboro, and Rock. The township had important herring fisheries in early times and manufactured straw hats (from 1828) and ladies' dress goods. Middleboro was settled about 1662 under the Indian name Nemasket; became a part of the township of Plymouth in 1663; and in 1669 was incorporated as a separate township, taking its name probably from Middlesbrough, North Riding, York.

See Thomas Weston, *History of the Town of Middleboro, Massachusetts* (Boston, 1906).

MIDDLEBURY, a village and the county-seat of Addison county, Vermont, U.S.A., in Middlebury township, on Otter Creek, about 31 m. N.N.W. of Rutland. Pop. of the village (1890), 1762; (1900), 1897 (221 foreign-born); (1910), 1866; of the township, (1900), 3045; (1910), 2848. Middlebury is served by the Rutland railroad. It is picturesquely situated near the Green Mountain range, and is the seat of Middlebury College (chartered, 1800; co-educational since 1883), which offers a classical course and a Latin-scientific course, and had in 1907–1908 12 instructors and 203 students (84 of whom were women), and a library of 35,000 volumes. The Sheldon art museum and a public library are among the public institutions of the village, and the principal buildings include the court-house and the opera-house. The principal industrial establishments are marble quarries, "Italian" marble works, iron foundries, lime-kilns, flour-mills, and door, sash and lumber mills. About 1 m. north of the village, in the township of Weybridge, there is a large United States government breeding station for Morgan horses; and merino sheep are raised in the vicinity.

The township of Middlebury was incorporated in 1761, and the first settlement on the site of the present village was made in 1773. At the outbreak of the War of Independence the settlement was deserted, and all except two or three of the houses were destroyed by British troops; but the settlers returned soon after the close of the war, and the township was formally organized and sent a member to the state assembly in 1788. Middlebury was incorporated as a borough in 1813, and as a village in 1832.

MIDDLESBROUGH, a municipal, county and parliamentary borough and seaport in the North Riding of Yorkshire, England, 238½ m. N. by W. from London, on the North Eastern railway. Pop. (1891), 75,532; (1901), 91,302. It lies on the south bank of the Tees, 5 m. from its mouth in the North Sea, and is the centre of one of the most important iron-working districts in the world. It is wholly of modern growth, having been incorporated in 1853. Its chief buildings are a fine town-hall with lofty clock-tower and spire (1889), containing the municipal offices, free library, &c.; the exchange, county court, Dorman memorial museum and Roman Catholic cathedral. Besides iron and steel works, the first of which was that of Messrs Bolckow, Vaughan & Co., there are rolling-mills, tube works, wire-mills, engineering works, oil works, chemical works, salt works and a considerable shipbuilding industry. The district abounds in blast furnaces. The docks are accessible to large vessels, the entrance having a depth of 32 ft. Extensive dredging operations are carried on in the river. The accommodation for shipping includes two graving docks, two patent slips, &c. The entrance to the river is protected by two breakwaters named respectively the North Gare and South Gare. The furnaces within the port produce some

2,500,000 tons of pig iron annually. Middlesbrough is the seat of a Roman Catholic bishop. The parliamentary borough falling within the Cleveland division of the county, returns one member. The county borough was created in 1888. The town is governed by a mayor, ten aldermen and thirty councillors. Area, 2823 acres.

The earlier history of the place is meagre. Where Middlesbrough now stands there were at one time a small chapel and priory founded by Robert de Brus of Skelton Castle. These were dedicated to St Hilda, and with some lands were given by de Brus to the abbey of St Hilda at Whitby in 1130. The priory fell into ruins at the time of the Reformation, and no trace now remains beyond some stones built into the wall of a brewery. The Oak Chair in the town-hall also is made from a fragment. In 1801 there were upon the site of Middlesbrough only four farmhouses. In 1829 a company styling itself the Middlesbrough Owners bought 500 acres of land, and began building in the town. In 1830 the Stockton & Darlington railway was extended to Middlesbrough; four years later the town was lighted with gas; and after six years more a public market was established. The census of 1831 showed the population to be 154; that of 1841 showed 5709. In 1842 the opening of the docks gave additional importance to the town. From the year 1851, when John Vaughan discovered the presence of ironstone in the Eston hills, the town advanced rapidly.

MIDDLESEX, LIONEL CRANFIELD, 1ST EARL OF (1575–1645), was a successful London merchant, who was introduced to King James I. by Henry Howard, earl of Northampton, and entered the royal service in 1605. In 1613 he was knighted and was appointed surveyor-general of customs; in 1616 he became one of the masters of requests, and in 1619 master of the court of wards and liveries and chief commissioner of the navy. He was returned to parliament as member for Hythe in 1614 and for Arundel in 1621. Cranfield, who was also master of the wardrobe, was responsible for many economies in the public service, and his business acumen was very useful to the king. He took part in the attack on Bacon in 1621, and although, contrary to general expectation, he did not succeed Bacon as lord chancellor, he was created Baron Cranfield in July of this year. In 1621 also he became lord high treasurer, and in September 1622 was created earl of Middlesex, losing his positions and influence shortly afterwards because he opposed the projected war with Spain, and had incurred the hostility of Prince Charles and George Villiers, duke of Buckingham. Impeached by the House of Commons for corruption, he was found guilty by the House of Lords in May 1624 and was sentenced to lose all his offices, to pay a heavy fine and to be imprisoned during the king's pleasure. However, he was released from prison in a few days, was pardoned in the following year, and was restored to his seat in the House of Lords in 1640. The earl's second wife was Anne Brett (d. 1670), a cousin of Buckingham's mother, whom he married somewhat reluctantly in 1621 in order to ensure Buckingham's support. Middlesex died on the 6th of August 1645, leaving with other issue a son James (1621–1651), 2nd earl of Middlesex, who was a partisan of the parliamentary party during the Civil War. James was succeeded by his brother, Lionel, and when this earl died in October 1674 his titles became extinct. The first earl's daughter Frances married Richard Sackville, 5th earl of Dorset, and their son Charles was created earl of Middlesex in 1675. Two years later he became earl of Dorset, and the title of earl of Middlesex was borne by the earls and dukes of Dorset until 1843.

MIDDLESEX, a south-eastern county of England, bounded N. by Hertfordshire, E. by Essex, S.E. by the county of London, S. by Surrey, and W. by Buckinghamshire. The area is 283·3 sq. m., and, excepting Rutland, the county is the smallest in England. The area outside the county of London, or extra-metropolitan area, with which this article is mainly concerned, is 233·8 sq. m. It lies entirely in the basin of the river Thames, which forms its southern boundary. On the east it is separated from Essex by the Lea, the largest northern tributary of the Thames. The other rivers, in order westward, are the Brent, the Crane or Yedding Brook, and the Colne. The waters of several streams are collected in the artificial Brent reservoir near Hendon, from which the Brent flows with a circuitous course to the Thames at Brentford. The Crane, rising in the high ground near Harrow-on-the-Hill, joins the Thames at Isleworth; and the Colne, which rises on the elevated plain between Hatfield and St Albans (Hertfordshire), traverses a flat valley on the western boundary of the county, where it divides into several channels, and joins the main river at Staines. The highest ground, exceeding 400 ft. at several points, and reaching 503 ft. above Stanmore, is found along the northern boundary, in a line from Stanmore through Elstree, Chipping Barnet and Potter's Bar. Two well-marked lines of heights, detached from the main line, project southward, the eastern from Whetstone through Finchley and Highgate to Hampstead, where, within the county of London, a height of 443 ft. is found on Hampstead Heath; the western being the isolated elevation on which stands Harrow-on-the-Hill. The hills skirting the Lea valley, in the neighbourhood of Enfield, are abrupt, though of no great elevation. Elsewhere the country is very slightly undulating or quite flat, as along the banks of the Thames and Lea. The Thames, however, beautifies its immediate neighbourhood, and rich sylvan scenery is not wanting in the higher districts. The greater part of the county was formerly densely forested and sparsely populated, and the name of Enfield Chase, a royal preserve in the north-east, still recalls this condition. In modern times the visible influence of London has spread over practically the entire county. Villages have grown into populous suburbs; large institutions, for which sites adjacent to rather than within the metropolis have been found preferable, are numerous, and the development of suburban railway communications has brought fresh ground within reach of builders.

Geology.—The county lies entirely within the structural basin of the Thames, and, as in the neighbouring counties, the general slope of the ground and dip of the strata is towards the south-east. South of an irregular line passing from Uxbridge, north of Hayes, by Hanwell and Ealing to Hyde Park and east of a similar line from the upper side of the Park to Tottenham and on from that point to Enfield, the only visible deposits are the gravels, loams, brick-earths and sands laid down in former times by the Thames, with contributions by the Lea and the Colne. These alluvial deposits rise gradually northward from the Thames and westward from the Lea, in a series of gentle terraces. The earliest portions of London were built upon these terraces, because while they were dry at the surface, water could be obtained by sinking shallow wells. The alluvium has yielded many flint implements and the bones of the mammoth, bear and rhinoceros, great elk and other extinct forms. The loams are dug for bricks and the gravel for ballast, &c., about West Drayton, Southall, Enfield and Tottenham.

The London clay, a marine deposit, is bluish where it has not been turned brown by exposure to the weather. It underlies all the river deposits and rises to the surface north and east of the alluvial boundary indicated above. It gives rise to the undulating grassy country round Harrow, Chipping Barnet and Elstree. Below the London clay are the more sandy Reading beds, they may be seen at Harefield and at South Mimms; inliers occur at Pinner and Ruislip. Chalk is only visible on the side of the Colne valley at Harefield, where it is quarried, and at South Mimms. Formerly, the sandy and pebbly Bagshot beds covered all the London clay area, but now only isolated patches remain, such as those on the top of Harrow, Hampstead and Highgate hills. Long after the Bagshot beds were laid down the country was covered by a variety of glacial deposits; such are the pebble gravels of Stanmore Heath and the district north of Barnet, the clay and sand of Finchley, Muswell Hill and Southgate, the chalky boulder clay to be seen at Finchley, Southgate and Potter's Bar. Several deep borings in the London basin prove the existence, beneath the chalk, of beds which do not crop out in Middlesex. The most interesting is that at Meux's Brewery, Tottenham Court Road (about 1146 ft.), which passes through the following formations: gravel and clay, 21 ft.; London clay, 64 ft.; Reading beds, 51 ft.; Thanet sand, 21 ft.; chalk, 655 ft.; upper greensand, 28 ft.; gault, 160 ft.; lower greensand, 64 ft.; Devonian rocks, 80 ft.[1]

Industries, &c.—The climate of some of the high-lying districts is particularly healthy. Little more than one-half the total area of the county is under cultivation; and the grain crops, greatly decreasing, are insignificant. The soil in the north and north-west is heavy, poor clay; but the rich alluvial soil of the Thames Valley is specially suitable for market gardens. On the outskirts of London much land now built over was formerly devoted to market gardening. The number of livestock decreases; in fact, agriculture as a whole has slowly to give place to extension of building. Industries are extensive and varied. The county is naturally, in view of the proximity of London, closely intersected with railways, the following companies, from east to west and south, affording communications: Great Eastern, Great Northern, Midland, London & North-Western, Metropolitan, Great Central, Metropolitan District, Great Western, London & South-Western. Moreover, in some parts the tramway system has been extended over a wide area from London; thus Uxbridge, in the extreme west of the county, is so served. The principal canals are the Grand Junction, running west from Brentford to the Colne Valley, and thence northward; with a branch (the Paddington Canal) connecting it with the Regent's Canal in London; and, in the east, the Lea navigation.

---

[1] See "Geology of Part of the London Basin," *Mem. Geol. Survey*, 2 vols.; "Soils and Subsoils," ditto; *Proceedings of the Geologists' Association.* A large model of the geology of London is exhibited in the Museum of Practical Geology, Jermyn Street, London.

Population and Administration.—The area of the ancient county is 181,320 acres, with a population in 1871 of 2,539,765; in 1891 of 3,251,671; and in 1901 of 3,585,323. At the time of the Domesday Survey the population of Middlesex, exclusive of London, was 2302. The extra-metropolitan area is 149,668 acres, with a population in 1901 of 798,738. The part of the ancient county transferred to the county of London under the Local Government Act 1888 was 31,484 acres in extent, and 771 acres were then transferred to Hertfordshire; while under the London Government Act 1899 the southern part of Hornsey was transferred to London. The area of the administrative county is 148,700 acres. The county contains six hundreds. The municipal boroughs are Ealing (pop. 33,031), Hornsey (72,056). The urban districts are Acton (37,744), Brentford (15,171), Chiswick (29,809), Edmonton (46,899), Enfield (42,738), Feltham (5280), Finchley (22,126), Friern Barnet (11,566), Greenford (819), Hampton (6813), Hampton Wick (2606), Hanwell (10,438), Harrow-on-the-Hill (10,220), Hayes (3000), Hendon (22,450), Heston and Isleworth (30,863), Kingsbury (757), Ruislip-Northwood (3850), Southall Norwood (13,200), Southgate (14,993), Staines (6688), Sunbury-on-Thames (4544), Teddington (14,037), Tottenham (102,541), Twickenham (20,991), Uxbridge (8585), Wealdstone (5901), Wembley (4519), Willesden (114,811), Wood Green (34,233). The county is in the jurisdiction of the central criminal court, and the whole extra-metropolitan county is within the metropolitan police district, the name of "Greater London" covering it. There are one court of quarter sessions and eight petty sessional divisions. The number of civil parishes is 60. Middlesex (extra-metropolitan) is wholly in the diocese of London, excepting a small portion in that of Oxford, and includes 153 ecclesiastical parishes or districts, wholly or in part. The extra-metropolitan parliamentary divisions, each returning one member, are Enfield, Tottenham, Hornsey, Harrow, Uxbridge, Brentford and Ealing.

History.—The district which is now Middlesex was colonized in the 6th century by an offshoot of the East Saxon tribe, and derived its name from its position between the kingdoms of the East and West Saxons. In a charter dated 704 Middlesex is mentioned by name as a dependency of Essex, but soon after it acknowledged the supremacy of Mercia, and from 748 onwards the Mercian council was held at London, and from 780 onwards at Brentford. In the 9th century Middlesex formed part of the Danelagh, and in 993 Anlaf the Dane came with 93 ships to Staines. The only reference to Middlesex in the Saxon Chronicle occurs in 1011, when it was again overrun by the Danes. The Conqueror's march upon London was preceded by a general devastation of the surrounding country, the effects of which are illustrated in the Domesday Survey by the diminution in land values. At this time the district north of London formed the vast forest of Middlesex, the greater part of which was disafforested in the reign of Henry III. Enfield had woodlands for 2000 pigs; Ruislip for 1500 pigs; and Kingsbury, Hillingdon and Hendon for 1000 pigs each. Vineyards are mentioned at Holborn, Colham, Kempton and Kensington; fishponds at Harmondsworth and Harefield produced each 1000 eels.

As a shire Middlesex probably originated about the time of the frith of 886, when it is described as the land dependent upon London, and in 912 is referred to as "London and the land which owed obedience thereto." During the Saxon period the extensive manors held by the church of Canterbury, the bishop of London and his canons of St Paul's, and the abbey of Westminster were held as independent franchises, the courts for St Paul's being held at Stepney and Fulham, for Westminster at Westminster and Staines, and for Canterbury at Harrow. By charter of Henry I. (confirmed by Stephen and Henry II.) the citizens of London held Middlesex at farm for £300, with power to elect a sheriff from among their number, and by charter from John the shrievalty of both London and Middlesex was granted to the mayor and citizens in fee. By charter of 1242 the common pleas for the county of Middlesex were ordered to be held at the stone cross in the Strand. Under a charter of 1447 the lord mayor was authorized to nominate one of the city aldermen as justice of the peace for Middlesex. The six modern hundreds of Edmonton, Elthorne, Gore, Isleworth, Ossulston, and Spelthorne have been scarcely changed since the Domesday Survey, except that Isleworth was then Honeslaw (Hounslow), while in the 12th century hidage a hundred of "Mimes" is mentioned, corresponding with the Domesday hundred of Edmonton. Middlesex has always been included in the diocese of London. The archdeaconry of Middlesex, which includes part of Essex, is mentioned in 1151, but the Middlesex portion was not subdivided into rural deaneries until 1857, when the deaneries of Fulham, Ealing, Uxbridge, Staines, Hampton, Enfield, Harrow and St Pancras were created. The deaneries of Chelsea, Hammersmith, Hampstead, Hornsey, Kensington, Paddington, St Marylebone, Westminster and Willesden were created later, but Staines was abolished.

In 1215 Middlesex was ravaged by William, earl of Salisbury, and Falkes de Breauté, and in the same year at Runnimede near Staines John was forced to issue the Magna Carta. In the Civil War of the 17th century Middlesex supported the Parliamentary cause, joining in 1642 with Hertfordshire and Essex in a petition that the votes of the bishops and popish lords might be disallowed in the House of Lords, and that the forts and castles of the kingdom might be placed in such hands as the Parliament could confide in. Sir Denzil Hollis was defeated by the Royalists at Brentford in 1642, and in 1645 a fruitless treaty between Charles I. and the Parliament was concluded at Uxbridge. Brentford had famous election contests in 1768 and 1769.

The woollen and leather industries flourished in Middlesex in Norman times. London was the great place of slaughter, and hides were tanned at Enfield. Bricks were also manufactured from early times, and Heston was noted for its wheat. Paper was extensively manufactured in the 17th century, and much distress was caused in 1636 by a decree prohibiting the purchase of old rags for the Middlesex paper-mills for fear of the plague. In 1640 the manufacturers of mohair yarn in Middlesex appealed against a bill prohibiting the wearing of material made of the said yarn during the winter season. In 1655 a certificate of a hundred master tanners and other traders of Middlesex approved an invention for converting raw hides into leather by means of new liquor, with or without oak-bark.

Middlesex returned two members to parliament in 1295. (For the representation of London, see London.)

See John Norden, *Speculum Britanniae: the firste parte, an historicall and chorographicall description of Middlesex* (London, 1593; reprinted 1637 and 1723); Daniel Lysons, *The Environs of London* (1792–1796); *Victoria County History, Middlesex.*

MIDDLETON, EARLS OF. John Middleton, 1st Earl of Middleton (*c.* 1619–1674), belonged to a Kincardineshire family which had held lands at Middleton since the 12th century. In early life he served as a soldier in France; later he fought against Charles I. both in England and in Scotland, being especially prominent at the battle of Philiphaugh and in other operations against the great Montrose. He held a high command in the Scottish army which marched to rescue the king in 1648, and he was taken prisoner after the battle of Preston. He joined Charles II. when that monarch reached Scotland in 1650, but he was soon at variance with the party which at that time was dominant in church and state and was only restored to favour after doing a public penance at Dundee. He was a captive for the second time after the battle of Worcester, where he commanded the Royalist cavalry, but he escaped from the Tower of London to Paris. In 1653 Middleton was chosen by Charles II. to head the projected rising in Scotland. He reached that country in February 1654, but the insurrection was a complete failure. Its leader, who cannot be held responsible for this result, remained in Scotland until 1655, when he rejoined Charles II., who made him an earl in 1656. He returned to England with the king in 1660 and was appointed commander-in-chief of the troops in Scotland and lord high commissioner to the Scottish parliament, which he opened in January 1661. He was an ardent advocate of the restoration of episcopacy, this being one reason which led to serious dissensions between the earl of Lauderdale and himself, and in 1663 he was deprived of his offices. He was afterwards (1667) governor of Tangier, where he died in June 1674.

His eldest son CHARLES, 2ND EARL OF MIDDLETON (c. 1640–1719), held several offices under Charles II. and James II., being envoy extraordinary at Vienna and afterwards joint secretary for Scotland. In 1684 he became an English secretary of state, and with Richard Graham, Viscount Preston, he had the difficult task of managing the House of Commons for James II. He was loyal to James after the king fled to France, although he remained in England, where, as the leader of the moderate Jacobites, he sought to bring about a restoration by peaceful means. In 1693 the earl joined the exiled king at St Germains, where he became his secretary of state; afterwards he held the same office at the court of James Edward, the old pretender, in Flanders and in Lorraine. He was partly responsible for the unsuccessful expedition of the Jacobites to Scotland in 1707, and he resigned his office as secretary in 1713. Middleton, who had been created earl of Monmouth by the pretender, died in 1719. His titles had been declared forfeited in 1695, but they were claimed by his son John, who died unmarried about 1746. The earl was a Protestant, although a lukewarm one, until 1701, when he yielded to the dying wish of James II. and joined the Roman Catholic Church.

One of Middleton's kinsmen was SIR CHARLES MIDDLETON, Bart. (1726–1813). Having served in the navy Middleton was comptroller of the navy from 1778 to 1790, "standing out through that period of inept administration as the pillar of the service." In April 1805, at a most critical time, he was, although eighty years of age, appointed first lord of the admiralty by Pitt and was created Lord Barham. It has been usual to regard Barham as a cipher at the admiralty board, but more recent research, especially an examination of the *Barham Papers*, has proved this to be the reverse of the truth. He enjoyed the absolute confidence of Pitt, and it was his experience, industry and energy which made possible the great campaign which ended at Trafalgar. He resigned office in January 1806 and died on the 17th of January 1813. His barony passed through his daughter Diana (1762–1823) to the Noels, earls of Gainsborough, by whom it is still held. The *Barham Papers* are being edited by Sir J. K. Laughton (vol. i. 1907; vol. ii. 1910). See also J. S. Corbett, *The Campaign of Trafalgar* (1910).

See A. C. Biscoe, *The Earls of Middleton* (1876).

MIDDLETON, ARTHUR (1742–1787), American politician and signer of the Declaration of Independence, was born at Middleton Place on the Ashley river, South Carolina, on the 26th of June 1742. His family was one of the most prominent in the colony. The grandfather, Arthur Middleton (1681–1737), was president of the Council in 1721–1730 and as such was acting governor in 1725–1730, and the father, Henry Middleton (1717–1784), was speaker of the Assembly in 1745–1747 and again in 1754–1755, a delegate to the Continental Congress in 1774–1776, and its president from October 1774 to May 1775, a member of the South Carolina Committee of Safety, and in 1775 president of the South Carolina Provincial Congress. Like most wealthy South Carolinians of the 18th century, Arthur Middleton was educated in England—at Hackney, at Westminster School, and at St John's College, Cambridge. He then returned to South Carolina, but soon afterwards went back to England to live, and travelled on the Continent. In 1773 he again returned to South Carolina, and in the controversies between the colonists and the home government became a leader of the Whigs. He was a member of the provincial Council of Safety in 1775–1776, and a delegate to the Continental Congress in 1776–1777. In 1778 he was elected governor of South Carolina, but owing to his dissatisfaction with the new state constitution he declined to serve. He was captured by the British at Charleston in May 1780, was exchanged in July 1781, was again a delegate to Congress in 1781–1783, and later served in the state legislature. He died on the 1st of January 1787 at Middleton Place, near Charleston.

His eldest son, HENRY MIDDLETON (1770–1846), was an orator of ability, was governor of South Carolina in 1810–1812, a representative in Congress in 1815–1819, and the United States minister to Russia from 1820 to 1830, negotiating in 1824 a convention "relative to navigation, fishing and trading in the Pacific Ocean, and to establishments on the North-West Coast." This was the first treaty between the United States and Russia.

MIDDLETON, CONYERS (1683–1750), English divine, was born at Richmond in Yorkshire on the 27th of December 1683. He graduated at Cambridge, took orders, and in 1706 obtained a fellowship, which he soon resigned upon contracting an advantageous marriage. In 1717 a dispute with Richard Bentley, who made an extortionate demand on the occasion of Middleton's being created D.D., involved him in an acrimonious controversy. He wrote several trenchant pamphlets, among them the "Remarks" and "Further Remarks" on Bentley's *Proposals for a New Edition of the Greek Testament*, an endeavour to visit his grievances upon the text of the New Testament. In 1723 he was involved in a lawsuit by personalities against Bentley, which had found their way into his otherwise judicious tract on library administration, written on the occasion of his appointment as university librarian. In 1726 he offended the medical profession by a dissertation contending that the healing art among the ancients was only exercised by slaves or freedmen. Between the dates of these publications he visited Italy, and made those observations on the pagan origin of church ceremonies and beliefs which he subsequently embodied in his *Letter from Rome* (1729). This cogent tract probably contributed to prepare the storm which broke out against him on his next publication (1731). In his remonstrance with Daniel Waterland on occasion of the latter's reply to Matthew Tindal's *Christianity as Old as the Creation*, Middleton takes a line which in his day could hardly fail to expose him to the reproach of infidelity. He gives up the literal truth of the primeval Mosaic narratives; and, in professing to indicate a short and easy method of confuting Tindal, lays principal stress on the indispensableness of Christianity as a mainstay of social order. This was to resign nearly everything that divines of the Waterland stamp thought worth defending. Middleton was warmly assailed from many quarters, and retreated with some difficulty under cover of a sheaf of apologetic pamphlets and a more regular attendance at church. His next important publication was a *Life of Cicero* (1741), largely told in that statesman's own words. Though Middleton's reputation was much enhanced by this piece of work, there is no doubt that he drew largely from the scarce book of William Bellenden, *De tribus luminibus Romanorum*. The work was undertaken at the instance of Lord Hervey, in correspondence with whom also originated his disquisition on *The Roman Senate*, published in 1747. The same year and the following produced the most important of all his writings, the *Introductory Discourse* and the *Free Inquiry* "concerning the miraculous powers which are supposed to have subsisted in the church from the earliest ages." In combating this belief Middleton indirectly established two propositions of capital importance. He showed that ecclesiastical miracles must be accepted or rejected in the mass; and he distinguished between the authority due to the early fathers' testimony to the beliefs and practices of their times, and their very slender credibility as witnesses to matters of fact. Some individual grudge seems to have prompted him to expose, in 1750, Bishop Sherlock's eccentric notions of antediluvian prophecy, which had been published 25 years before. On the 28th of July 1750 he died at Hildersham, near Cambridge.

Middleton's most ambitious work is obsolete from no fault of his, but his controversial writings retain a permanent place in the history of opinion. In his more restricted sphere he may not inappropriately be compared with Lessing. Like Lessing's, the character of his intellect was captious and iconoclastic, but redeemed from mere negation by a passion for abstract truth, too apt to slumber until called into activity by some merely personal stimulus. His diction is generally masculine and harmonious. Pope thought him and Nathaniel Hooke the younger the only prose writers of the day who deserved to be cited as authorities on the language. Samuel Parr, while exposing his plagiarisms, heaps encomiums on his style. But his best qualities, his impatience of superstition and disdain of mere external authority, are rather moral than literary.

The best general view of his intellectual character and influence is to be found in Sir Leslie Stephen's *English Thought in the Eighteenth Century*, ch. vi. A handsome edition of his works, containing several posthumous tracts, but not including the *Life of Cicero*, appeared in 4 vols. in 1752 and in 5 vols. in 1755.

MIDDLETON, THOMAS (*c.* 1570–1627), English dramatist, son of William Middleton, was born about 1570, probably in London. There is no proof that he studied at either university, but he may be safely identified with one of the Thomas Middletons entered at Gray's Inn in 1593 and 1596 respectively. He began to write for the stage with *The Old Law*, in the original draft of which, if it dates from 1599 as is generally supposed, he was certainly not associated with William Rowley and Philip Massinger, although their names appear on the title-page of 1656. By 1602 he had become one of Philip Henslowe's established playwrights. The pages of Henslowe's *Diary* contain notes of plays in which he had a hand, and in the year 1607–1608 he produced no less than six comedies of London life, which he knew as accurately as Dekker and was content to paint in more realistic colours. In 1613 he devised the pageant for the installation of the Lord Mayor, Sir Thomas Middleton, and in the same year wrote an entertainment for the opening of the New River in honour of another Middleton. From these facts it may be reasonably inferred that he had influential connexions. He was frequently employed to celebrate civic occasions, and in 1620 he was made city chronologer, performing the duties of his position with exactness till his death.

The most notable event in his career was the production at the Globe theatre in 1624 of a political play, *A Game at Chess*, satirizing the policy of the court, which had just received a rebuff in the matter of the Spanish marriage, the English and Spanish personages concerned being disguised as the White Knight, the Black King, and so forth. The play was stopped, in consequence of remonstrances from the Spanish ambassador, but not until after nine days' performances, and the dramatist and the actors were summoned to answer for it. It is doubtful whether Middleton was actually imprisoned, and in any case the king's anger was soon satisfied and the matter allowed to drop, on the plea that the piece had been seen and passed by the master of the revels, Sir Henry Herbert. Middleton died at his house at Newington Butts, and was buried on the 4th of July 1627.

He worked with various authors, but his happiest collaboration was with William Rowley, this literary partnership being so close that F. G. Fleay (*Biog. Chron. of the Drama*) treats the dramatists together. The plays in which the two collaborated are *A Fair Quarrel* (printed 1617), *The World Lost at Tennis* (1620), an ingenious masque, *The Changeling* (acted 1624, printed 1653), and *The Spanish Gipsie* (acted 1623, printed 1653). The main interest of the *Fair Quarrel* centres in the mental conflict of Captain Ager, the problem being whether he should fight in defence of his mother's honour when he no longer believes his quarrel to be just. The underplot, dealing with Jane, her concealed marriage, and the physician, which is generally assigned to Rowley, was suggested by a story in Giraldi Cinthio's *Hecatommithi*. *The Changeling* is the most powerful of all the plays with which Middleton's name is connected. The plot is drawn from the tale of Alsemero and Beatrice-Joanna in Reynolds's *Triumphs of God's Reveng against Murther* (bk. i., hist. iv.), but the story, black as it is, receives additional horror in Middleton's hands. The famous scene in the third act between Beatrice and De Flores, who has murdered Piracquo at her instigation, is admirably described by Swinburne:

> "That note of incredulous amazement that the man whom she has just instigated to the commission of murder 'can be so wicked' as to have served her end for any end of his own beyond the pay of a professional assassin, is a touch worthy of the greatest dramatist that ever lived. . . . That she, the first criminal, should be honestly shocked as well as physically horrified by revelation of the real motive which impelled her accomplice into crime, gives a lurid streak of tragic humour to the lifelike interest of the scene; as the pure infusion of spontaneous poetry throughout redeems the whole work from the charge of vulgar subservience to a vulgar taste for the presentation or the contemplation of criminal horror."

Leigh Hunt thought that the character of De Flores, for effect at once tragical, probable and poetical, "surpassed anything with which he was acquainted in the drama of domestic life." The underplot of the piece, though it is based on the humours of a madhouse, has genuine comic flashes. *The Spanish Gipsie* has a double plot based on the *Fuerza de la sangre* and the *Gitanilla* of Cervantes Much has been said on the collaboration of Middleton with Rowley, who was much in demand with fellow-dramatists, especially for his experience in low comedy. These plays, even in scenes where the evidence in favour of one or other of the collaborators is clear, rise to excellence which neither dramatist was able to achieve alone. It was clearly no mechanical partnership the limits of which can be said to be definitely assigned when the actual text has been parcelled out between the collaborators.

With Thomas Dekker he wrote *The Roaring Girle, or Moll Cut-Purse* (1611). The frontispiece represents Moll herself in man's attire, indulging in a pipe of tobacco. She was drawn or idealized from life, her real name being Mary Frith (1584–1659?), who was made to do penance at St Paul's Cross in 1612. "Worse things, I must confess," says Middleton in his preface, "the world has taxed her for than has been written of her; but 'tis the excellency of a writer to leave things better than he finds 'em." In the play she is the champion of her sex, and is equally ready with her sword and her wits. Middleton is also credited with a share in Thomas Dekker's *Honest Whore* (pt. i., 1604). *The Witch*, first printed in 1778 from a unique MS., now in the Bodleian, has aroused much controversy as to whether Shakespeare borrowed from Middleton or vice versa. The dates of both plays being uncertain, there are few definite data. The distinction between the two conceptions has been finely drawn by Charles Lamb, and the question of borrowing is best solved by supposing that what is common to the incantations of both plays was a matter of common property. *The Mayor of Quinborough* was published with Middleton's name on the title-page in 1661. Simon, the comic mayor, is not a very prominent character in the plot, which deals with Vortiger, Hengist, Horsus and Roxena among other characters. One of its editors, Mr Havelock Ellis, thinks the proofs of its authenticity as Middleton's work very slender. It is generally supposed to have been a very early work subjected to generous revision.

The plays of Middleton still to be mentioned may be divided into romantic and realistic comedies of London Life. Dekker had as wide a knowledge of city manners, but he was more sympathetic in treatment, readier to idealize his subject. *Two New Playes. Viz.: More Dissemblers besides Women. Women beware Women*, of which the former was licensed before 1622, appeared in 1657. The plot of *Women beware Women* is a double intrigue from a contemporary novel, *Hyppolito and Isabella*, and the genuine history of Bianca Capello and Francesco de Medici. This play, which ends with a massacre appalling even in Elizabethan drama, may be taken as giving the measure—no mean one—of Middleton's unaided power in tragedy.

The remaining plays of Middleton are: *Blurt, Master-Constable. Or the Spaniards Night-walke* (1602); *Michaelmas Terme* (1607), described by A. C. Swinburne as an excellent Hogarthian comedy; *The Phoenix* (1607), a version of the Haroun-al-Raschid trick; *The Famelie of Love* (1608); *A Trick to catch the Old-one* (anonymously printed, 1608); *Your Five Gallants* (licensed 1608); *A Mad World, my Masters* (1608); *A Chast Mayde in Cheapside* (printed 1630), notable for the picture of Tim, the Cambridge student, on his return home; *Anything for a Quiet Life* (*c.* 1617, printed 1662); *No Wit, No Help like a Woman's* (*c.* 1613, printed 1657); *The Widdow* (printed 1652), on the title-page of which appear also the names of Ben Jonson and John Fletcher, though their collaboration may be doubted. Eleven of his masques are extant. A tedious poem, *The Wisdom of Solomon paraphrased, by Thomas Middleton*, was printed in 1597, and *Microcynicon, Six Snarling Satires by T. M. Gent*, in 1599. Two prose pamphlets, dealing with London life, *Father Hubbard's Tale* and *The Black Book*, appeared in 1604 under his initials. His non-dramatic work, however, even if genuine, has little value.

AUTHORITIES.—His works were edited by Alexander Dyce (5 vols.) in 1840, with a valuable introduction quoting many documents, and by A. H. Bullen (8 vols.) in 1885. *The Best Plays of Thomas Middleton* were edited for the Mermaid series (1887) by Havelock Ellis with an introduction by A. C. Swinburne. See also Miss P. G. Wiggin's *Inquiry into the Authorship of the Middleton-Rowley Plays* (Boston, 1897), and the notice on Middleton in Professor A. W. Ward's *Hist. of Eng. Dram. Lit.* (ed. 1899; ii., 493–540), which contains a full account of Middleton's *Game at Chesse.* A careful examination of the parallelisms between the plays of Shakespeare and Middleton is made by D. Hugo Jung in "Das Verhältnis Thomas Middleton's zu Shakspere" (*Münchener Beiträge zur roman. u. engl. Phil.* vol. xxix., 1904).

MIDDLETON, a market town and municipal borough in the Middleton parliamentary division of Lancashire, England, on the Irk, near the Rochdale Canal, and on the Lancashire & Yorkshire railway, 6 m. N.N.E. from Manchester. Pop. (1901), 25,178. The church of St Leonards is of mixed architecture, with a low square tower. The oldest portion of the building (the tower arch) dates from the 12th century, but the main portion from 1412, and the south aisle from 1524. Two chapels in it contain memorials of, and are named after, two ancient Lancashire families, the Asshetons and the Hopwoods. The Queen Elizabeth grammar-school, a building in the Tudor style, was founded in 1572 by Nowell, dean of St Paul's, London. There are a handsome town-hall and municipal technical schools. An extensive system of tramways and electric light railways connects the town with its suburbs and adjacent industrial centres. The prosperity of the town dates from the introduction of manufactures at the close of the 18th century. The staple trade is the spinning and weaving of cotton, and the other industries include silk weaving, calico-printing, bleaching, dyeing, iron-founding and the manufacture of soap and chemicals. There are collieries in the neighbourhood. The town was incorporated in 1886, and the corporation consists of a mayor, 6 aldermen and 18 councillors. Area, 4775 acres.

MIDDLETOWN, a city and the county-seat of Middlesex county, Connecticut, U.S.A., in the township of Middletown, in the south central part of the state, on the west bank of the Connecticut river, about 30 m. from its mouth, and about 15 m. south of Hartford. Pop. (1890), 9013; (1900), 9589, of whom 2316 were foreign-born; (1910 census) 11,851. Within a radius of 2 m. from the city hall there was found in 1910 most of the township's population of 20,749. The city is served by two branches of the New York, New Haven & Hartford railroad, by a line of coast steamers, and by electric lines connecting with neighbouring cities and villages. The city is connected by a long highway bridge with the village of Portland in the township of Portland (pop. in 1910, 3425; area 26 sq. m.), which is known for its brown-stone quarries. Four miles south of Middletown is Chestnut Mountain (or Bull Hill), which commands a fine view; and about 3 m. east are the "Narrows" of the Connecticut river, where the water flows between high hills. Middletown has a number of handsome residences. In High Street stand the buildings of Wesleyan university (Methodist Episcopal), founded in 1831 by the Rev. Wilbur Fisk, who became the first president and the Rev. Laban Clark (1778–1868), who became the first president of the board of trustees. Women were first admitted in 1872, but coeducation was later discontinued, and the last freshman class of women students under the old system entered in 1909. The university offers classical and scientific courses, and in 1908–1909 had 36 instructors, 322 students (30 being women), and a library of 79,000 volumes. In 1875–1877 the work of the first agricultural experiment station in the United States was carried on here under state supervision in Wesleyan University, with Professor Wilbur Olin Atwater (1844–1907) as director; it was then removed to New Haven. Middletown is also the seat of the Berkeley divinity school (Protestant Episcopal), founded in 1849 as the theological department of Trinity College, Hartford, rechartered and removed to Middletown in 1854, and having in 1907 a faculty of 8, and 16 students; and the city has a free public library (1874) with 17,700 vols. in 1907. South-east of the city is the Connecticut hospital for the insane, and south-west of the city, the Connecticut industrial school for girls (reformatory). The total value of the factory products in 1905 was $5,604,676, an increase of 35 % over that for 1900. The municipality owns and operates the waterworks.

Middletown occupies the site of an Indian village, Mattabesec or Mattabesett (from *Massa-sepues-et,* "at a great rivulet or brook"), the principal village of the Mattabesec Indians, an Algonquian tribe which included the Wongunk, Pyquaug and Montowese Indians and seems to have had jurisdiction over the whole of south-western Connecticut. The township of Middletown was settled by whites in 1650, and until 1653, when the present name was adopted, was known by the Indian name, Mattabesett. It was incorporated in 1651; and the city was chartered in 1784. Shipbuilding and commerce became the principal sources of wealth. In the middle of the nineteenth century Middletown was one of the leading cities of Connecticut, and as late as 1886 it was a port of entry; but the development of rival ports, especially New Haven, Hartford and Bridgeport, into railway centres, retarded the growth of manufacturing, and commerce declined after the Civil War.

MIDDLETOWN, a city of Orange county, New York, U.S.A., on the Wallkill river, 67 m. N.N.W. of New York City. Pop. (1890) 11,977; (1900) 14,522, including 1700 foreign-born and 480 negroes; (1905, state census) 14,516; (1910) 15,313. It is served by the Erie, the New York, Susquehanna & Western, and the New York, Ontario & Western railways, and is connected by an electric line with Goshen (pop. in 1910, 3081), the county-seat. It is situated in an attractive dairy and agricultural country; and in the city and vicinity there are many summer residences. Here are the state homoeopathic hospital for the insane, a state armoury, Thrall hospital, and Thrall library. Middletown is primarily a manufacturing city, and has the car shops of the New York, Ontario & Western railway. The value of its factory products increased from $2,154,742 in 1900 to $3,356,330 in 1905, or 55·8 %. The municipality owns and operates its waterworks. Middletown was settled about 1706 and owed its early commercial importance to its being a "half-way house" (whence its name) for travellers on the Minisink Road to western New York, and it was for a time a terminus of the Erie railroad. It was incorporated as a village in 1848, and first chartered as a city in 1888.

MIDDLETOWN, a city of Butler county, Ohio, U.S.A., on the Miami river, 34 m. N. of Cincinnati. Pop. (1890), 7681; (1900), 9215, of whom 769 were foreign-born and 314 were negroes; (1910) 13,152. It is served by the Cleveland, Cincinnati, Chicago & St Louis, the Cincinnati, Hamilton & Dayton, the Cincinnati Northern (New York Central system), and a branch of the Cincinnati, Lebanon & Northern (Pennsylvania system) railways. It is the trade centre of a rich and beautiful agricultural region in which tobacco, wheat and Indian corn are the principal crops. The river furnishes considerable water-power and the total factory product in 1905 was valued at $8,357,993, an increase of 47·2 % over that in 1900. The waterworks are owned and operated by the municipality. Middletown was laid out in 1802 and was named from its location between Cincinnati and Dayton; it was incorporated in 1833.

MIDDLETOWN, a borough of Dauphin county, Pennsylvania, U.S.A., on the east bank of the Susquehanna river, 9 m. below Harrisburg. Pop. (1890), 5080; (1900), 5608 (340 foreign-born and 289 negroes); (1910), 5374. It is served by the Pennsylvania and the Philadelphia & Reading railways, and by an electric line to Harrisburg. The borough has a considerable trade with the surrounding agricultural country, and owing to the proximity of the Yorkhaven power-plant (across the river) and the excellent railway service, is a manufacturing centre. The municipality owns its electric lighting plant. Middletown was founded in 1755 by Friends (from Philadelphia and other places in Pennsylvania) and Scotch-Irish, and was so named because of its position midway between Lancaster and Carlisle. It was first incorporated as a borough in 1828.

MIDDLEWICH, an urban district in the Northwich parliamentary division of Cheshire, England, 166 m. N.W. of London, on the London & North Western railway. Pop. (1901), 4669. It lies in open country near the river Dane, having water communications by the Trent and Mersey canal, and a branch giving access to the Shropshire Union canal. The church of St Michael and All Angels is of various periods and contains numerous monuments. In the streets not a few old buildings remain, making for picturesqueness, and a number of the fine timbered houses in which Cheshire abounds are seen in the immediate neighbourhood. Middlewich shares in the salt industry common to several towns, such as Northwich and Winsford, in this part of the county; there are also chemical works and a manufacture of condensed milk.

MIDHAT PASHA (1822–1884), Turkish statesman, the son of a civil judge, was born at Constantinople in 1822. His father, a declared partisan of reform, trained him for an administrative career, and at the age of twenty-two he was attached as secretary to Faïk Effendi, whom he accompanied in Syria for three years. On his return to Constantinople Midhat was appointed chief director of confidential reports, and after a new financial mission in Syria was made second secretary of the grand council. His enemies, however, succeeded in ousting him from this post, and caused him to be entrusted with the apparently impossible task of settling the revolt and brigandage rampant in Rumelia. His measures were drastic and their success was startling and the government made him an official of the first rank and restored him to his place in the grand council. In similar vigorous fashion he restored order in Bulgaria in 1857. In 1860 he was made vizier and pasha, and entrusted with the government of Nisch, where his reforms were so beneficial that the sultan charged him, in conjunction with Fuad Pasha and Ali Pasha, to prepare the scheme for adapting them to the empire which was afterwards known as the law of the vilayets. After further administrative work in his province, he was ordered to organize the council of state in 1866, and was then made governor of Bagdad, where his success was as decisive as at Nisch, but attended with much greater difficulties. In 1871 the anti-reform influence of the grand vizier, Mahmoud Nedim, seemed to Midhat a danger to the country, and in a personal interview he boldly stated his views to the sultan, who was so struck with their force and entire disinterestedness that he appointed Midhat grand vizier in place of Mahmoud. Too independent, however, for the court, Midhat remained in power only three months, and after a short governorship of Salonica he lived apart from affairs at Constantinople until 1875.

From this time forward, however, Midhat Pasha's career resolved itself into a series of strange and almost romantic adventures. While sympathizing with the ideas and aims of the "Young Turkey" party, he was anxious to restrain its impatience, but the sultan's obduracy led to a coalition between the grand vizier, the war minister and Midhat Pasha, which deposed him in May 1876, and he was murdered in the following month. His nephew Murad V. was in turn deposed in the following August and replaced by his brother, Abdul Hamid II. Midhat Pasha now became grand vizier, reforms were freely promised, and the Ottoman parliament was inaugurated with a great flourish. In the following February, however, Midhat was dismissed and banished for supposed complicity in the murder of Abdul Aziz. He then visited various European capitals, and remained for some time in London, where he carefully studied the procedure in the House of Commons. Again recalled in 1878, he was appointed governor of Syria, and in August exchanged offices with the governor of Smyrna. But in the following May the sultan again ordered him to be arrested, and although he effected his escape and appealed to the powers, he shortly afterwards saw fit to surrender, claiming a fair hearing. The trial accordingly took place in June, when Midhat and the others were sentenced to death. It was, however, generally regarded as a mockery, and on the intercession of the British government the sentence was commuted to banishment. The remaining three years of his life were consequently spent in exile at Taif in Arabia, where he died, probably by violence, on the 8th of May 1884. To great ability, wide sympathies, and undoubted patriotism he added absolute honesty, that rare quality in a vizier, for he left office as poor as when he entered it. (G. F. B.)

MIDHURST, a market town in the north-western parliamentary division of Sussex, England, 12 m. N. by E. of Chichester by the London, Brighton & South Coast railway; served also by the London & South Western railway. Pop. (1901), 1674. It is pleasantly situated on slightly rising ground near the river Rother. The church of St Mary Magdalen and St Denis is a large Perpendicular building. The town retains several picturesque old houses, and in the vicinity, by the river, are the ruins of the 16th century mansion of Cowdray, burnt down in 1793. A grammar-school was founded at Midhurst in 1672 and attained some eminence. After being closed for many years it was re-opened in 1880. In 1906 a magnificent sanatorium for consumptives was opened about 4 m. from Midhurst; it bears the name of King Edward VII., who laid its foundation stone and opened it.

The name of Midhurst (Middeherst, Mudhurst) first occurs in the reign of Henry I. when Savaric Fitz-Cana held it of the honour of Arundel, then presumably in the king's hands. The charter of Henry I., although no longer extant, is quoted in later confirmation charters of Richard I., Henry III., Edward III. and Richard II. Franco de Bohun inherited Midhurst from his uncle Savaric Fitz-Savaric, and the De Bohuns held the lordship until 1499 when Sir David Owen obtained it through his marriage with the daughter of the last male heir. He sold it to Sir William Fitz-William, from whom it passed to Sir Anthony Browne and descended to the viscounts Montague. Midhurst is definitely called a borough in the reign of Edward I., but the borough-court and market were probably in existence much earlier. It was governed by a bailiff, elected annually, until the office lapsed, probably early in the 19th century. In an act of 1883 it is mentioned as one of the towns which had long ceased to be municipal. No charter of incorporation is known. Midhurst returned two members to parliament from 1300–1301 till 1832, and from that date one member until 1885 when it was disfranchised. In the reign of Henry VI. a market was held by the burgesses every Thursday, and a fair on Whit-Tuesday, by grant from Sir John Bohun. In 1888 the fair-days were the 6th of April, the 9th of May and the 29th of October. The market-day was Thursday. Pleasure-fairs are still held on the 6th of April and the 29th of October, but there is no market.

MIDIAN (properly Madyān, so Sept.), in the Bible, one of the peoples of North Arabia whom the Hebrews recognized as distant kinsmen, representing them as sons of Abraham's wife Ketūrah ("incense"). Thus the sons of Ketūrah are the "incense-men," not indeed inhabitants of the far south incense-land, but presumably the tribes whose caravans brought the incense to Palestine and the Mediterranean ports. So the Midianites appear in connexion with the gold and incense trade from Yemen (Isa. lx. 6), and with the trade between Egypt and Syria (Gen. xxxvii. 28, 36). They appear also as warriors invading Canaan from the eastern desert, and ravaging the land as similar tribes have done in all ages when Palestine lacked a strong government (see Gideon). Again, they are described as peaceful shepherds, and the pastures of the Midianites, or of the branch of Midian to which Moses's father-in-law (Jethro or Reuel, or Hobab) belonged, lay near Mount Horeb (Exod. iii. 1). The Kenites who had friendly relations with Israel, and are represented in Judg. i. 16, iv. 11, as the kin of Moses's father-in-law, appear to have been but one fraction of Midian which took a separate course from their early relations to Israel.[1] Balaam, according to one version of the story, was a Midianite (Num. xxii. seq.) and his association with Moab has been connected with the statement in Gen. xxxvi. 35, that the Edomite king Hadad defeated Midian in the land of Moab; (see Balaam, Edom).

---

[1] The admixture of Midianite elements in Judah and the other border tribes of Israel is confirmed by a comparison of the names of the Midianite clans in Gen. xxv. 4 with the Hebrew genealogies (1 Chron. ii. 46, Ephah; iv. 17, Epher; Gen. xlvi. 9, Hanoch). Epher is also associated with 'Ofr near Ḥanākiya (Hanoch), three days north from Medina, also with Apparu a Bedouin locality mentioned by Assur-bani-pal. Ephah is probably the Ḥayapa transported by Sargon to Beth-Omri (Samaria).

A place Midian is mentioned in 1 Kings xi. 18, apparently between Edom and Paran, and in later times the name lingered in the district east of the Gulf of ʽAkaba, where Eusebius knows a city Madiam in the country of the Saracens and Ptolemy (vi. 7) places Modiana. Still later Madyan was a station on the pilgrim route from Egypt to Mecca, the second beyond Aila (Elath). Here in the middle ages was shown the well from which Moses watered the flocks of Shoʽaib (Jethro), and the place is still known as "the caves of Shoʽaib." It has considerable ruins, which have been described by Sir R. Burton (*Land of Midian*, 1879).

This district which has on its east Taimā, a centre of civilization in the 5th century B.C., and on its south-east El-ʽOlā whose existence as a seat of culture is possibly even older, is identified by some scholars with the Muṣrān of the Minaean (south Arabian) inscriptions, on which see SABAEANS, YEMEN. That this part of north-west Arabia had frequent intercourse with Palestine appears certain from its commercial relations with Gaza; and the association of the Midianite Jethro with early Hebrew legislation, as also the possibility that Mizraim ("Egypt") in the Old Testament should be taken in some cases to refer to this district, have an important bearing upon several Old Testament questions. See MIZRAIM.

MIDLETON, WILLIAM ST JOHN FREMANTLE BRODRICK, 9TH VISCOUNT (1856–   ), English politician, was the son of the 8th viscount (1830–1907). He came of a Surrey family who in the 17th century, in the persons of Sir St John Brodrick and Sir Thomas Brodrick, obtained grants of land in the south of Ireland. Sir St John Brodrick settled at Midleton, between Cork and Youghal in 1641; and his son Alan Brodrick (1660–1728), speaker of the Irish House of Commons and lord chancellor of Ireland, was created Baron Brodrick in 1715 and Viscount Midleton in 1717 in the Irish peerage. In 1796 the title of Baron Brodrick in the peerage of the United Kingdom was created. The English family seat at Peper Harow, near Godalming, Surrey, was designed by Sir William Chambers. The 8th viscount was a Conservative in politics, who for a few years had a seat in the House of Commons, and who was responsible in the House of Lords for carrying the Infants Protection Act. His brother, the Hon. G. C. Brodrick, was for many years warden of Merton College, Oxford. As Mr St John Brodrick, the 9th viscount had a distinguished career in the House of Commons. After being at Eton and Balliol, Oxford, and serving as president of the Oxford Union, he entered parliament as conservative member for one of the Surrey divisions in 1880. From 1886 to 1892 he was financial secretary to the war office; under secretary for war, 1895–1898; under secretary for foreign affairs, 1898–1900; secretary of state for war, 1900–1903; and secretary of state for India, 1903–1905. He lost his seat for the Guildford division of Surrey at the general election of January 1906. In March 1907 he was made an alderman of the London County Council. He married, first in 1880, Lady Hilda (d. 1901), daughter of the 9th earl of Wemyss, by whom he had a family; and secondly in 1903, Madeleine Stanley, daughter of Lady St Helier by her first husband.

MIDLETON, or MIDDLETON, a market town of Co. Cork, Ireland, on the river Owenacurra, 13 m. E. of Cork by the Youghal branch of the Great Southern & Western railway. Pop. (1901), 3361. The river here enters a branch of Cork harbour. The surrounding hilly country is pleasant and fertile, and furnishes the town with a good agricultural trade. There are also whisky-distilleries. Ballinacurra, 1½ m. south on the estuary, serves as a small port. The grammar school was founded in 1696, and here among its students were John Philpot Curran and Isaac Butt. Midleton is governed by an urban district council.

MIDNAPORE, a town and district of British India, in the Burdwan division of Bengal. The town is 68 m. W. of Calcutta; it has a station on the Bengal Nagpur railway. Pop. (1901), 33,140. It is an important centre of trade, being the terminus of a navigable canal to Calcutta, and also the junction for the Sini branch of the Bengal-Nagpur railway. There are manufactures of brass and copper wire. It has an American mission, a municipal college, and a public library founded in 1852.

The DISTRICT OF MIDNAPORE has an area of 5186 sq. m. The general appearance is that of a large open plain, of which the greater part is under cultivation. In the northern portion the soil is poor, and there is little wood. The country along the western boundary, known as the Jungle Mahals, is undulating and picturesque; it is almost uninhabited. The eastern and south-eastern portions are swampy and richly cultivated. The chief rivers of the district are the Hugli and its three tributaries, the Rupnarayan, the Haldi and the Rasulpur. The Midnapore high-level canal used also for irrigation runs almost due east and west from the town of Midnapore to Ulubaria on the Hugli 16 m. below Calcutta, and affords a continuous navigable channel 53 m. in length. There is also a tidal canal for navigation, 26 m. in length, extending from the Rupnarayan river. The district is traversed as well by the Bengal-Nagpur railway towards Orissa, with a branch to Chota Nagpur. The jungles in the west of the district yield lac, tussur, silk, wax, resin, fire-wood, charcoal, &c., and give shelter to large and small game. The principal exports are rice, silk and sugar; and the chief imports consist of cotton cloth and twist. Salt, indigo, silk, mats and brass and copper utensils are manufactured. Both silk and indigo are decaying industries. The population in 1901 was 2,789,114, showing an increase of 6% in the decade.

The early history of Midnapore centres round the ancient town of Tamluk, which in the beginning of the 5th century was an important Buddhist settlement and maritime harbour. The first connexion of the English with the district dates from 1760, when Mir Kasim ceded to the East India Company Midnapore, Chittagong, and Burdwan (then estimated to furnish one-third of the entire revenue of Bengal) as the price of his elevation to the throne of Bengal on the deposition of Mir Jafar.

MIDRASH, a very common term in Jewish writings for "exposition" and a certain class of expository literature. The word also occurs twice in the Old Testament (2 Chron. xiii. 22, xxiv. 27; R.V. rather poorly "commentary").

1. *Introduction.*—The term (Heb. *midrāsh* from *dārash* "to search out, enquire") denotes some explanation or exposition, which, in contrast to the more literal exegesis (technically called *pĕshat* "simple"), endeavours to reach the spirit lying below the text. It may be defined as a didactic or homiletic development of some thought or theme, characterized by a more subjective, imaginative and ampliative treatment. Jewish Midrash falls broadly into two classes: *Halaka* (*q.v.*) or *Hălākā* (walking, way, conduct) and *Haggādah* (narrative [with a purpose], homily; Aramaic equivalent *Aggādah*; the incorrect form *Agadah* rests upon a mistaken etymology). The former dealt with legal and ritual matters; it flourished in the schools and developed into the most subtle casuistry. The latter covered all non-halakic exposition and was essentially popular. It embraced historical and other traditions; stories, legends, parables and allegories; beliefs, customs and all that may be called folk-lore. It fed itself, not upon the laws, but upon the narrative, the prophetical and the poetical writings of the Old Testament, and it had a more spiritual and ethical tone than the Halaka. In both classes, accepted tradition (written or oral) was reinterpreted in order to justify or to deduce new teaching (in its widest sense), to connect the present with a hallowed past, and to be a guide for the future; and the prevalence of this process, the innumerable different examples of its working, and the particular application of the term Midrash to an important section of Rabbinical literature complicates both the study of the subject and any attempt to treat it concisely.[1] Apart from the popular paraphrastic translations of the Old Testament (see TARGUM), the great mass of orthodox Rabbinical literature consists of (1) the independent Midrāshīm, and (2) the Mishna which, with its supplement the Gĕmārā, constitutes the Talmud. Both contain Halaka and Haggada, although the Mishna itself is essentially Halaka, and the Midrashim are more especially Haggadic; and consequently further information bearing upon Midrash must be sought in the art. TALMUD. These two articles

[1] For a careful study of the meaning of the term, see W. Bacher, *Jew. Quart. Rev.* IV. 406–429.

handle one of the most famous bodies of ancient literature, which, in its turn, has given rise to innumerable Jewish and non-Jewish works, and has many points of value and interest which cannot be adequately discussed here. It must suffice, therefore, to deal rather broadly with the subject, and to refer for fuller details to the special encyclopaedias, viz.: Hamburger's *Real-Encyc. für Bibel und Talmud*, and the very elaborate articles in the *Jewish Encyclopedia*.

2. *Narrative Midrash.*—Of the three different kinds of historical writing—the genetic or scientific, the purely narrative and the pragmatic—it is the last which has prevailed among religious historians. It is extremely difficult to avoid the subjective element in dealing with matters of fact, and the religious treatment of history is influenced, however unconsciously, by the mental environment of the writers. In giving greater prominence to events of religious importance and to their bearing upon the spiritual needs of contemporaries they view and interpret the past in a particular light, and will see in the past those growths which only in their own time have become mature. A latent significance is found, a particular connexion is traced, and a continuity is established, the true nature of which must be tested by critical students. Now, it is subjective history which we find in the earliest references to Midrash. The Midrash of the prophet Iddo (2 Chron. xiii. 22) like the Visions and the Histories of Iddo and Shemaiah (ix. 29, xii. 15) which are quoted for the lives of Solomon, Abijah and Jeroboam, are evidently quite distinct from the sources cited in the parallel portions of the earlier compilation, and the entire spirit of the narratives is different. Similarly, there is a conspicuous difference of treatment of the life of Joash in 2 Kings xi. seq., compared with 2 Chron. xxiii. seq., which refers to some Midrash of the Book of the Kings (xxiv. 27). Although it is uncertain whether this comprehensive Midrash also included the "books of the Kings" (xvi. 11, xxvii. 7, &c.), and the Midrash of Iddo and other related works, it is clear that the Book of Chronicles (*q.v.*) marks a very noteworthy advance upon the records in the (canonical) Book of Kings (*q.v.*). It is now recognized that the compiler of the former has used many novel narratives of a particular edifying and didactic stamp, and scholars are practically unanimous that these are subsequent to the age of the Israelite monarchy and present a picture of historical and religious conditions which (to judge from *earlier* sources) is untrustworthy. At the same time various details (as comparison with the Book of Kings shows) are relatively old and, on a priori grounds, it is extremely unlikely that the unhistorical elements are necessarily due to deliberate imagination or perversion rather than to the development of earlier traditions. The religious significance of the past is dominant, and the past is idealized from a later standpoint; and whether the narratives in Chronicles are expressly styled Midrash or not, they are the fruit of an age which sought to inculcate explicitly those lessons which, it conceived, were implied in the events of the past. The value of the book lay not in history for its own sake, but in its direct application to present needs. But the tendency to reshape history for the edification of later generations was no novelty when Chronicles was first compiled (about 4th cent. B.C.), Pragmatic historiography is exemplified in the earliest continuous sources (viz. of the "Deuteronomic" writers, *i.e.* allied to Deut., especially the secondary portions); and there are many relatively early narratives in which the details have been modified, and the heroes of the past are the mouthpiece for the thought of a later writer or of his age. Numerous instructive examples of the active tendency to develop tradition may be observed in the relationship between Genesis and the "Book of Jubilees," or in the embellishments of Old Testament history in the *Antiquities* of Josephus, or in the widening gaps in the diverse traditions of the famous figures of the Old Testament (Adam, Noah, Enoch, Abraham, Moses, Isaiah, Ezra, &c.), as they appear in non-canonical writings. In such cases as these one can readily perceive the different forms which the same material elements have assumed, and one may distinguish the unreliable accretions which are clearly later and secondary. Accordingly, when there are narratives which cannot be tested in this manner, should they show all the internal marks of didactic expansion and date from an age much later than the times with which they deal, their immediate value will not necessarily lie in the details which appear to be of historical interest, but in their contribution to later forms of tradition and phases of thought. So far then, Midrash tends to include moralizing history, whether we call it narrative or romance, attached to names and events, and it is obviously exemplified whenever there are unmistakable signs of untrustworthy amplification and of some explicit religious or ethical aim colouring the narrative. This, however, is only one of the aspects which have to be taken into consideration when one advances to the Rabbinical Midrash.

For Old Testament "Midrash" see further K. Budde, *Zeitschr. f. alt-test. Wissenschaft*, xii. 37, seq., and commentaries on Chronicles (*q.v.*). The elaborate study by the Jewish scholar Zunz (*Die gottesdienstlichen Vorträge*, ch. viii.) is also valuable for bridging the gulf between the canonical and the non-canonical traditions and for its just attitude to the criticism of historical traditions. The rigid line between fact or fiction in religious literature, which readers often wish to draw, cannot be consistently justified, and in studying old Oriental religious narratives it is necessary to realize that the teaching was regarded as more essential than the method of presenting it. "Midrash" which may be quite useless for historical investigation may be appreciated for the light it throws upon forms of thought. Historical criticism does not touch the reality of the ideas, and since they may be as worthy of study as the apparent facts they clothe, they thus indirectly contribute to the history of their period. In any case, while the true historical kernel of the Midrashic narrative (*e.g.* dealing with Adam, Moses or Isaiah) will always be a matter of dispute, the teaching to which it is applied stands on an independent footing as also does the application of that teaching to other ages.

3. *Continuity of Literature and Material.*—Amid obscure vicissitudes in the 7th to 5th centuries, B.C., the Canonical books of the Old Testament gradually began to assume their present shape (see PALESTINE: *History*). The internal peculiarities show that the compilations are the much edited remains of a larger body of literature, and it may reasonably be supposed that the older sources did not at once perish. There is literary critical evidence for late insertions by exilic or later compilers;[1] the compiler of Chronicles apparently refers to accessible works; and there is a close material relationship between the Old Testament and later literature. All this suggests that Old Hebrew writings, apart from those preserved in the Canon, persisted to a relatively late period. No a priori distinction can be made and no precise chronological line can be drawn between the books of the Canon (Canticles, Ecclesiastes, Esther, Ezekiel and Proverbs had been at one time or another subjects of debate among the Rabbis) and the Apocrypha (Ecclesiasticus, Judith, Maccabees and Tobit, were "allowed"); and the intimate relation between them appears in the character of the "Wisdom Literature" (*e.g.* Proverbs, and the Wisdom of Solomon), in the treatment of the stories of Esther and Daniel (the history of Susanna), and also in the twofold recensions Ezra and 1 Esdras. Historical or narrative Midrash is exemplified in the "canonical" books Daniel, Esther, Jonah and Ruth, and in the "apocryphal" stories of Daniel (viz. Susanna, where the point lies in the name Daniel "God is judge"), Esther, Judith, Tobit (and the Ahiqar cycle of stories), the story of Zerubbabel (1 Esd. iii. seq., the sequel of which belongs to the canonical Ezra), and the martyrdom of Eleazer (2 Macc. vi. seq., compare 4 Macc.). This is not the place to notice the course of Jewish literary activity in Palestine or Alexandria, whether along the more rigid lines of Pharisaic legalism (the development of the canonical "priestly" law), or the popular and less scholastic phases, which recall the earlier apocalyptical tendencies of the Old Testament and were cultivated alike by early Jewish and Christian writers. But after the fall of Jerusalem, partly through the need for systematizing the traditional post-biblical law, and partly through disputes with the Christians, orthodox Rabbinism received the stamp which has since characterized it. The traditional or oral law was codified in the Mishna (see TALMUD, § 1 seq.), the Canon was

---

[1] *E.g.* Judg. i. (see G. F. Moore, *Ency. Bib.* "Historical Lit.," col. 2085, middle), 2 Sam. ix.-xx., &c.

fixed, and the fluctuations in the MSS. of the Old Testament (which, like the numerous variations in the Septuagint, complicated exact exegesis) gave way to what was virtually a single text. Moreover, the important body of apocalyptical and pseudepigraphical literature, with all its links between Christianity and Judaism, fell into disfavour on both sides. This literature is especially valuable because it illustrates contemporary Halaka and Haggada, and it illuminates the circle of thought with which Jesus and his followers were familiar; it thus fills the gap between the Old Testament and the authoritative Rabbinical Midrashim which, though often in a form several centuries later, not rarely preserve older material.[1]

A few miscellaneous examples of related Midrashic details may be cited:—

i. The book of Jubilees (a haggadic and halakic Midrash on Genesis, about 2nd century B.C.), contains the story of the war between Amorite Kings and Jacob (ch. xxxiv.). This is known to the probably contemporary Testament of Judah and to much later Midrashim (*Mid. Wayyisā'ū*, *Yalqūt Shimeonī*, also the apocryphal "book of Jashar"), and is evidently connected with the cryptic allusion to the capture of Shechem in Gen. xlviii. 22 (R.V. marg.). Unless we suppose that the latter was suddenly expanded into the stories which thenceforth persisted, it may be inferred that an old extra-canonical tradition (for which a case can be made) continued to survive the compilation of Genesis (*q.v.*) and ultimately assumed the various exaggerated forms now extant. Naturally the probability of such a tradition—the merest hint of which happens to be preserved in Gen. *loc. cit.*—does not prejudice the problem of its origin or accuracy; in Jub. the story is useless for Jacob's history, and is probably influenced by a recollection of more recent events in the Maccabaean age.

ii. A curious account of war between Egypt and Canaan after Joseph's death recurs in *Jub.* xli., *Test. of Simeon*, viii., and *Benjamin* vii., and is connected with details (burial of Jacob's sons at Hebron) recorded by Josephus (*Ant.* ii. 8). Josephus in turn has another story wherein Moses leads the Egyptians against Ethiopia (*Ant.* ii. 10, for parallels see Moore, *Ency. Bib.* col. 2089 seq.), and this is found in the late chronicles of Jerahmeel and the Book of Jashar (cf. also *Mid. Dibrē ha-yāmīm shel-Mōsheh*; see *Jew. Ency.* viii. 573 seq.). The former may be linked with Gen. l. 9 (where the concourse of chariots and horsemen would invite speculation), and the latter with the Cushite wife of Moses; but although one may grant that the canonical sources do not by any means preserve all the older current traditions, the contents of the latter cannot be recovered from the later persisting Midrashim.[2]

iii. The allusion in Jude *v.* 9 to the contention of the archangel Michael for the body of Moses belongs to a group of traditions which have been collected by R. H. Charles (*Assumption of Moses*, pp. 105 seq.), and it appears that the incident was familiar to Clement of Alexandria, Origen and other early writers. Moreover, Jude *v.* 16 agrees very closely with the Latin version of the Testament of Moses, which has other parallels in Matt. xxiv. 29; Acts vii. 36, 38 seq. (ibid. pp. lxii. seq.). Here may be added Jannes and Jambres, who withstood Moses (2 Tim. iii. 8); these or related names were known to the elder Pliny (xxx. i. 11), Apuleius (first half of 2nd century), Origen (who refers to a book of Jannes and Mambres), and various earlier and later Jewish sources; see I. Abrahams, *Ency. Bib.* col. 2327 seq.; H. St J. Thackeray, *Relation of St Paul to contemporary Jewish thought* (London, 1900), pp. 215 sqq.

iv. Jewish traditions of Abraham in Ur of the Chaldees recur in the Targums, Midrashic works, and earlier in the book of Jubilees (ch. xii., ed. Charles, p. 91; cf. also Judith v. 6 seq.). The legends of his escape from a fiery furnace may have a philological basis (*ūr* interpreted as "fire"), but the allusion to the redemption of Abraham in Isa. xxix 22 seems to indicate that older tradition was fuller than the present records in Genesis, and supplies another example of the link connecting the Old Testament with Rabbinical thought.

v. Not to multiply examples further, it may suffice to refer to (*a*) the apparent belief that the serpent tempted Eve to unchastity (2 Cor. xi. 2 seq., see Thackeray pp. 50 seq.); (*b*) the descent of the angels upon earth (Gen. vi. 1 seq.; Jude 6, 14 seq., see Charles, *Jub.* p. 33 seq., Clermont-Ganneau, *Quart. Statements of the Pal. Explor. Fund*, 1903, pp. 233 seq. and the Midr. *Abkir.* see *Jew, Ency.* viii. 572); (*c*) the relationship between the Midrashic developments of the story of Esther in Josephus, the Greek and Old Latin Versions, the Targums and later Jewish sources (see L. B. Paton, Comm. on *Esther*, pp. 20, 100 and *passim*); and finally (*d*) the numerous minor miscellaneous parallels noticed in recent annotated editions of the pseudepigraphical literature (especially those of R. H. Charles). (See further Talmud, § 5.)

4. *Midrashic Exposition.*—The Talmud poetically describes Midrash as a hammer which wakes to shining light the sparks which slumber in the rock; and the simile is a happy one when one considers the exegetical implements, the workmen and their workmanship. For the expository or interpretative Midrash was bound up with rules and methods which often appear crude and arbitrary, they are nevertheless those of the age and they helped to build up lasting monuments.[3] It was believed that the Written Word had an infinite fulness; according to the *Midr. Bemidbar Rabbah* every word of the Law had seventy different aspects, and Philo of Alexandria held that there are no superfluous words in Scripture. Consequently an exaggerated emphasis is often laid upon single words; as, for example, in the school of Rabbi 'Aqība, where even individual letters were forced to reveal their meaning. Thus, since the Hebrew *eth*, which marks the accusative, is also the preposition "with," Deut. x. 20 ("thou shalt fear [*eth*-] Yahweh thy God") was interpreted to include the veneration of the doctors of the law *along with* Yahweh.[4] Many examples of literal interpretation can of course be found, but arbitrary cases of the kind just noticed are due either to an obviously far-fetched interpretation or to the endeavour to find some authoritative support for teaching which it was desired to inculcate. Thus faulty proof rather than faulty inference is illustrated when the word "in-number" (Ex. xii. 4) was used to confirm the Halaka that the man who killed the Passover Lamb must know how many people were about to share it (*Jew. Ency.* viii. 570). Often the biblical text cannot be said to supply more than a hint or a suggestion, and the particular application in Halaka or Haggada must be taken on its merits, and the teaching does not necessarily fall because the exegesis is illegitimate. To take another specimen: the *Mekilta* on Ex. xx. 25 infers from the unusual form of the word "it," that the prohibition of iron applies only to *it, i.e.* the altar, and not to stones used in building the temple. This Halaka is followed by a haggadic explanation of the prohibition: "iron abridges life while the altar prolongs it; iron causes destruction and misery, while the altar produces reconciliation between God and man; and therefore the use of iron cannot be allowed in making the altar."[5] Such were the sparks that could be hammered out of the rock, and it is instructive to observe similar exegetical methods in the New Testament. Emphasis upon a single word is illustrated by Gal. iii. 16, where the argument rests upon the word "seed" (and not the plural "seeds") in the proof-text, and the same word in Rabbinical writings is used to support other arguments.[6] By identical kinds of exegesis Lev. xix. 14 (not to put a stumbling block before the blind) is the ground for cautioning a father against striking an adult child, and Deut. xxv. 4 (the law of the muzzled ox) is used to show that God's labourer is worthy of his hire.[7] Again, since through Eve sin entered into the world, woman must be subordinate to man (1 Tim. ii. 11–14), or, she who has thus extinguished "the light of the world" should atone by lighting the festal candles on the sabbath (Talm. *Shabb.* 5*b*). By the allegorical method Isa. lxi. is interpreted as applying to Jesus (Luke iv. 16–22), and frequently passages which originally had another application have a Messianic reference in

[7] The Talmud *Mō'ed Qaṭan*, 7*a*, and New Testament (1 Cor. ix. 9, 1 Tim. v. 18) respectively.

Christian and Rabbinical teaching. Similarly the application of Hos. ii. 23, not to the scattered tribes of Israel, but to the Gentiles, is common to the Mishna and to Romans ix. 25 seq. (Sanday and Headlam, *Comment. ad loc.*) The Apostle Paul, once a disciple of the famous Rabbi Gamaliel, uses in 1 Cor. x. 4 ("the spiritual rock that followed them") a familiar Jewish Haggada which, however, he reinterprets, even as, when he identifies the "rock" with Christ, he diverges from the Alexandrian Philo who had identified it with Wisdom or the Word of God. Moreover, not only are passages thus taken out of their context, but they are combined, especially when they contain the same words or phrases, or appear to have the same or similar thoughts or aims. The Talmud, with a reference to Prov. xxxi. 14 ("she bringeth her food from afar"), says "the words of the Torah are poor (or deficient) in one place but rich in another." Hence in the *Mid. Siphrē* on Numbers xv. 39, "ye shall not seek after . . . your own eyes" is explained to refer to adultery, after the words of Samson "she is pleasing in my eyes" (Judg. xiv. 3); and on Deut. vi. 5 it charges man to love the Lord "with all thy soul . . . even if he should take away thy soul," the teaching being based upon Ps. xliv. 22.[1] Similarly, in the New Testament, after the same method, Mal. iii. 1 and Is. xl. 3 (linked by the phrase "to prepare the way") are combined in Mark i. 2 seq.; Abraham's faith (Gen. xv. 6) and temptation (xxii. 1) are associated in James ii. 21-23, as also in contemporary Jewish thought; and by other combined quotations Paul enunciates the universality of sin (Rom. iii. 10 sqq.) and the doctrine that Christians are God's temple (2 Cor. vi. 16 sqq). Proceeding upon such lines as these, the Jews wove together their Midrashic homilies or sermons where, though we may find much that seems commonplace, there are illuminating parables and proverbs, metaphors and similes, the whole affording admirable examples of the contemporary thought and culture, both of the writers and—what is often overlooked—the level of their hearers or readers. Like many less ancient discourses, the Midrashim are apt to suffer when read in cold print, and they are sometimes judged from a standpoint which would be prejudicial to the Old Testament itself. But they are to be judged as *Oriental* literature and if they contain jarring extravagances and puerilities, one may recall that even in modern Palestine it was found that the natives understood *Robinson Crusoe* as a religious book more readily than the *Pilgrim's Progress* (J. Robertson, *Early Rel. of Israel*, 1892, p. 66). In making allowance for the defects (without which they would probably not have appealed to the age) it must be remembered that some of the Rabbis themselves recognized that the Midrashic Haggada was not always estimable.

An interesting example of combined quotation is illustrated in Matt. xii. 4-8, where the teaching of Jesus on the law of the Sabbath rests upon 1 Sam. xxi. 1-6, Num. xxviii. 9 seq. and Hos. vi. 6. Apropos of this law the Rabbinical arguments are worth noticing. Apparently the severe rules laid down in Jubilees l. 8-12 (see R. H. Charles, *ad loc.*) were exceptional. It was allowed that the Sabbath need not be too rigorously kept, and this was justified by Exod. xxxi. 13, where the singular use of the restrictive particle *ak* (EV "verily") supported the teaching that other Sabbaths need not be observed. Also, from the words "holy unto you" (*v.* 14) it was taught that "the Sabbath is given to you to desecrate in case of need, but thou art not given to the Sabbath." Hence the Sabbath might be broken when life was in danger. Moreover, it was argued that a battle need not be stopped from religious considerations, *e.g.* the Sabbath. This was justified by Deut. xx. 20 "until it fall" (Talm. *Shabb.* 19*a*). Also, the Passover Lamb could be sacrificed on the Sabbath, and justification for this was found in Num. ix. 2 "in its season" (*Pesah.* 66*a*). See further on this subject, and on the evasions of the Sabbath law, S. Shechter, *Studies in Judaism*, pp. 297 sqq.; ibid. in C. G. Montefiore, *Hibbert Lectures* (for 1892), Appendix; ibid. *Hastings' Dict. Bib.* v. 63, and also S. R. Driver, *Hastings' Dict.* iv. 320 seq. With the above interpretations, cf. A. H. McNeile on Matt. xii. 5, John vii. 23: "the à priori element in them perhaps suggests that [these verses] were due to later reflexion on the part of Christians who had realized the inadequacy of the law" (Swete's *Camb. Bibl. Essays*, 1909, p. 226). For other examples illustrating Rabbinical methods of exegesis in the New Testament, see McNeile, pp. 221, sqq. ("Our Lord's use of the Old Testament"); Briggs, *op. cit.* pp. 436, sqq., and Thackeray, *op. cit.* (ch. vii. "use of the Old Testament," ch. viii. "St Paul the Haggadist"). The latter observes (p. 203): "the arguments by which Paul tried to convince his opponents of the true meaning of the Old Testament as pointing forward to Christ, are those which they would themselves have employed for another purpose; and to some extent we need not doubt that they were selected for that very reason. They were the arguments which were best calculated to appeal to them." Quite in accordance with Rabbinical custom is the system of question and answer (Rom. x. 5, seq., 16 seq.), and the argument in the sequence: statement, objection and reply, appears already in the book of Malachi (*q.v.*).

5. *The Jewish Midrashim.*—The earlier stages in the growth of the extant Rabbinical Midrashim cannot be traced with any certainty. Although there are several allusions to early written works, other references manifest an objection to the writing down of Haggada and Halaka. Perhaps it was felt that to preserve uniformity of teaching in the schools it was undesirable to popularize the extant collections, or perhaps the references must be reconsidered in the light of those significant changes after the fall of Jerusalem which have been mentioned above (§ 3).[2] However this may be, the independent Hălākōth (where the oral decisions are interpreted or discussed on the basis of the Old Testament) were gradually collected and arranged according to their subject in the Mishnah and Tōsephtā (TALMUD, § 1), while in the halakic Midrashim (where the decisions are given in connection with the biblical passage from which they were derived) they follow the sequence of the text of the Old Testament. The Haggada was likewise collected according to the textual sequence of the Old Testament. But the sermons or discourses of the *homiletic* Midrashim are classified according to the reading of the Pentateuch in the Synagogue, either the three year cycle, or else according to the sections of the Pentateuch and Prophetical books assigned to special and ordinary Sabbaths and festival days. Hence the latter are sometimes styled Pesiqta ("section"). The homiletic Midrashim are characterized by (*a*) a proem, an introduction based upon some biblical text (not from the lesson itself), which led up to (*b*) the exposition of the lesson, the first verse of which is more fully discussed than the rest. They conclude (*c*) with Messianic or consolatory passages on the future glory of Israel. A feature of some Midrashim (*e.g.* nos. 4, 5*d*, *e*, and 7 below) is the halakic exordium which precedes the proems.[3]

Among the more important Midrashim are: i.—*Mĕkilta* (Aram. "measure," *i.e.* "rule") best known as the name of a now imperfect halakic Midrash on Exod. xii.–xxiii. 19 (also xxxi. 12-17 and xxxv. 1-3). It represents the school of R. (Rabbi) Ishmael, is a useful source for old Haggadah (especially on the narrative portions of Exodus), and is interesting for its variant readings of the Canonical Massoretic text.[4] Edited by Blasius Ugolinus, *Thes. Antiq. Sacr.* xiv. (Venice, 1744, with a poor Latin translation), more recently by J. H. Weiss (Vienna, 1865) and M. Friedmann (ibid. 1870), Germ. trans. by J. Winter and A. Wünsche Leipzig, 1909). See further J. Z. Lauterbach, *Jew. Ency.* viii. 444 seq.

ii. *Siphrā* (Aram. "the book") or *Tōrath Kōhănīm* ("the law of the priests"), a commentary on Leviticus, mainly halakic, the text being a source for various maxims. (On Lev. xix. 17 seq., neighbourly love and abstinence from vengeance constitute, according to R. Aqiba, the great principle of the Torah.) It is useful for the interpretation of the Mishnah treatises *Qŏdāshīm* and *Ṭĕhārōth*. Latin trans. in Ugolinus, vol. xiv.; recent editions by I. H. Weiss (Vienna, 1862), and with the commentary of Shimshon (Samson) of Siens (Warsaw, 1866); see *Jew. Ency.* xi. 330 sqq.

iii. *Siphrē* (Aram. "the books"), an old composite collection of Halaka on Numbers, after R. Ishmael's school; and on Deut. after that of R. Aqiqa, although the haggadic portions belong to the former. Latin in Ugol. xv.; recent edition, with good introduction by Friedmann (Vienna, 1864); see *Jew. Ency.* xi. 332 seq.

The above works, although of 5th century or later date in their present form, contain much older material, which was perhaps first redacted in the earlier part of the 2nd century, A.D. They are of

[2] See, on this point, *Jew. Ency.* viii. 549 seq., 552, 576; Schechter, *op. cit.* p. 62; Strack, *op. cit.* pp. 10 sqq.

[3] See more fully *Jew. Ency.* viii. 553. Cf. for the structure, the hopeful concluding notes in the prophecies (*e.g.* Amos) and the discourse after the reading of the lesson from the prophets in Luke iv. 17 sqq., Acts xiii. 15 sqq.

[4] See I. Abrahams in Swete's *Cambridge Bibl. Essays* (1909), pp. 174 seq.

Palestinian origin, although the main redaction was made in Babylonia.[1]

iv. *Tanḥūmā*, one of the oldest on the lessons of the Pentateuch, with many proems ascribed to R. Tanḥūmā ben ("son of") Abbā, one of the most famous haggadists of Palestine (4th century), who systematized and fixed the haggadic literature. This collection of 158–161 homilies is also known as *T. Yelammedēnū*, from the opening words, *Yel. Rabbēnū*, "our Rabbi teaches us"; on the critical questions connected with the titles and the present redaction (probably 5th century), see *Jew. Ency.* viii. 560 seq., xii. 44 sqq. Recent edition by Buber (Wilna, 1885).

v. *Midrash Rabbah* (or *Rabboth*), a large collection of very diverse origin and date, probably not completed before the 13th century. It covers the Pentateuch (1st ed., Constantinople, 1512) and the "Five Rolls" (Pesaro, 1519; the whole printed first at Venice, 1545); Germ. trans. by A. Wünsche, *Bibliotheca rabbinica* (Leipzig, 1880–1885). The several portions are named after the ordinary Jewish titles of the Old Testament books with the addition of *Rabbah* "great." These are (*a*) *Bĕrēshith* ("in the beginning," Gen. i. 1) *Rabbah*, on Genesis, the oldest and most valuable of haggadic Midrashim. Traditionally ascribed to R. Hōshaiah (3rd. century), but in the main a redaction of 6th century. Ed. J. Theodor; see *Jew. Ency.* iii. 62 seq.; viii. 557 seq. (*b*) *Shēmōth* ("names" Exod. i. 1) *R.*, a composite and incomplete work of 11th and 12th century date, but valuable nevertheless for its Tanḥūmā homilies. Exod. i.–xi. is a commentary on the text in continuation of (*a*).[2] See *Jew. Ency.* viii. 562 (*c.*) *Wayyiqrā* ("and he called") *R.*, on Leviticus, perhaps 7th century, based upon sources in 2 and 5*a* above. It is characterized by its numerous proverbs (*e.g.* on xix. 6: "do not care for the good pup of a bad dog, much less for the bad pup of a bad dog"). See *Jew. Ency.* viii. 560, xii. 478 seq. (*d*) *Bemidbar* ("in the desert of . . . ") *R.*, 33 homilies on Numbers, mainly derived from 4 above (though in an earlier text), with a later haggadic exposition, perhaps of 12th century, on Num. i.–vii. See *Jew. Ency.* ii. 669 sqq., viii. 562. (*e*) *Dĕbārīm* ("words") *R.*, independent homilies on Deuteronomy, of about A.D. 900, but with a good collection of Tanḥūmās and excerpts from the old sources. See *Jew. Ency.* iv. 487 seq. (*f*) *Shir* ("song") *R.*, or (after the opening words) *Aggadath Ḥazith*, a late compilation of haggadah on Canticles, illustrating the allegorical interpretation of the book in reference to the relation between God and Israel (so already in the exegesis of R. Aqiba, cf. also 2 Esd. v. 24, 26, vii. 26). For this and other Mid. on this popular book, see *Jew. Ency.* viii. 564 seq., xi. 291 seq. (*g*) *Mid. Ruth* or *Ruth Rabbah*, a compilation including an exposition of 1 Chron. iv. 21–23, xi. 13–15 and interesting Messianic references. For this and similar Mid. on Ruth, see *Jew. Ency.* viii. 565, x. 577 seq. (*h*) *Ékāh* ("how") *Rabbathi*, a compilation of about the 7th century on Lamentations, from sources cited also in the Palestinian Talmud. Thirty-six proems precede the commentary. See *Jew. Ency.* v. 85 seq. (*i*) *Mid. Koheleth* or *Koh. Rabbah*, on Ecclesiastes; see *Jew. Ency.* vii. 529 sqq.; viii. 565. (*j*) *Mid. Megillath Esther*, dating, to judge from its indebtedness to Josippon (the pseudo-Josephus), after 10th century. On this and other similar works dealing with this ever-popular book, see *Jew. Ency.* v. 241, viii. 566, and Paton's Comment. on Esther, p. 104.

vi. *Pesiqtā* ("section") or *P. de-Rab Kāhana*, contains 33 or 34 homilies (on the principal festivals), the first of which opens with a sentence of R. Abba bar Kahana, who was confused with a predecessor, Rab Kahana. Although it goes back to early Haggada it has received later additions (as is shown by the technique of the proems). Edited by S. Buber (Lyck, 1868), Germ. trans. by A. Wünsche (Leipzig, 1885); see *Jew. Ency.* viii. 559 seq. Not to be confused with this is:—

vii. *Pesiqtā Rabbāthi.*—A very similar but larger collection of 51 homilies, of which 28 have a halakic exordium prefixed to the Tanḥūmā–proems, perhaps of 9th century. Edited by M. Friedmann (Vienna, 1880). Quite another and later work is the *Pēs. Zūtarta* or *Leqaḥ Tōb* of Tobiah b. Eliezer of Mainz (trans. Ugolinus, vol. xv. seq.; ed. Buber, 1880); see *Jew. Ency.* viii. 561 sqq.

viii. In addition to the more prominent Midrashim mentioned above there are numerous self-contained works of greater or less interest. Some are connected with Old Testament books; *e.g. Aggadath Bereshith*, 83 homilies on Genesis, each in three parts connected with a section from the lectionary of the Pentateuch, and one from the Prophets, and a Psalm (ed. Buber, Cracow, 1903; see *Jew. Ency.* viii. 563); the *Mid. Tehillīm* on the Psalms (Germ. trans. A. Wünsche, Trier, 1892–1893), &c. Others are historical, *e.g. Pirqe* or *Baraitha de-Rabbi Eliezer*, a fanciful narrative of events selected from the Pentateuch, &c.; the eschatology is interesting. Though associated by name with a well-known 1st century Rabbi, it is hardly earlier than the 8th (Latin trans. by Vorstius, Leiden, 1644; see *Jew. Ency.* viii. 567). Further, the *Megillath Ta'anith* ("roll of fasts"), an old source with a collection of miscellaneous legends, &c.; *Megillath Antiokhos*, on the martyrdom under Hadrian; *Seder 'Olām Rabbah*, on biblical history from Adam to the rebellion of Bar Kōkba (Barcocheba); the "Book of Jashar"; the Chronicle of Jeraḥmeel," &c. Liturgical Midrash is illustrated by the *Haggada shel Pesaḥ*, part of the ritual recited at the domestic service of the first two Passover evenings. In *Mid. Ta'ame Ḥăsērōth we-Yĕthērōth*, Hebrew words written "defectively" or "fully," and other Massoretic details, are haggadically treated. Finally Kabbalah (*q.v.*) is exemplified in *Ōthiyyōth de R. Aqība* on the alphabet, and *M. Tadshe* (or *Baraitha de-R. Phineḥas b. Yā'īr*), on groups of numbers, &c.; of some interest for its relation to the book of Jubilees.

ix. Of collections of Midrash the chief are (*a*) the *Yalqūṭ Shimeoni*, which arranges the material according to the text of the Old Testament (extending over the whole of it), preserves much from sources that have since disappeared, and is valuable for the criticism of the text of the Midrashim (recent ed. Wilna, 1898) translation of the Yalqut on Zechariah by E. G. King (Cambridge, 1882; see further *Jew. Ency.* xii. 585 seq.). (*b*) *Yal. ha-Makiri*, perhaps later, covers only certain books, is useful for older sources and their criticism; portions have been edited by Spira (1894, on Isaiah); Buber (1899, on Psalms); Grünhut (1902, on Proverbs). (*c*) *Midrash ha-Gādōl* ("the great"), an extensive thesaurus, but later (quoting from Ibn Ezra, Maimonides, &c.); the arrangement is not so careful as in (*a*) and (*b*). See further *Jew. Ency.* viii. 568 seq.

Of modern collections special mention must be made of A. Jellinek's *Bet ha-Midrasch* (Leipzig, 1853) and A. Wünsche's valuable translations; to those already mentioned must be added his *Aus Israels Lehrhallen* (excerpts of a more miscellaneous character (Leipzig, 1907 sqq.).

Besides dictionary articles on this subject (S. Schiller-Szinessy, *Ency. Brit.*, 9th ed.; H. L. Strack, *Real-Ency. f. Protest. Theol. u. Kirche*; and especially J. Theodor and others in the *Jew. Ency*), see D. Hoffmann, *Zur Einleitung in die halachischen Midraschim* (Berlin, 1888), and the great work by Zunz, *Die gottesdienstlichen Vorträge der Juden*, 2nd ed. by N. Brüll (Frankfort on Main, 1892). These, as also the citations in the course of this article, give fuller information. (See further TALMUD.) (S. A. C.)

MIDSHIPMAN, the title in the British and American navies of the "young gentlemen" who are serving in order to qualify themselves to hold a commission as lieutenant. The English midshipman was originally a petty officer, one of the crew under the immediate orders of the boatswain. After the restoration of King Charles II., in 1660, the king and his brother, James Duke of York, lord high admiral, decided to train officers for the sea service. They therefore decided to send a volunteer to each ship of a squadron in commission, with a "letter of service," which instructed the admirals and captains that the bearer was to be shown "such kindness as you shall judge fit for a gentleman, both in accommodating him in your ship and in furthering his improvement." He was to receive the pay of a midshipman, and one midshipman less was to be borne in the ship. Until 1729 the young gentlemen who entered the British navy were known as "king's letter boys." In that year the system was altered. A school, known as the naval academy, was founded at Portsmouth in which forty lads were to be trained for the sea service. In 1773 the school, having proved unsatisfactory, was reorganized and the number of boys to be trained there increased from forty to seventy. In 1806 it was again reorganized, under the name of the naval college, and was finally suppressed in 1837, when the practice of training the boys under instructors in the ships was introduced. A special school was re-established in 1857, and was finally placed in the "Britannia." In the meantime the number of midshipmen had increased far beyond one for a ship. A line-of-battle ship in the 18th century carried as many as twenty-four, and the title had come to be confined entirely to those who were being trained as officers. The immense majority of officers of the British navy never passed through the academy or the college. They entered the ships directly as "captains' servants" or "volunteers," and were rated midshipman, if there was a vacancy, at the age of fifteen. As they were expected to learn navigation, they were instructed by the master, and at the age of seventeen were supposed to be qualified to be masters' mates. To-day the midshipman is the officer of the British and American navies who has passed through the preliminary schools and has been appointed to a ship. The French equivalent is *aspirant*, and other European navies use that name, or *cadet*.

---

[1] They contain (as I. Abrahams has pointed out to the present writer) a good deal of haggada, but far more halakic material than those which follow. The latter (nos. 4 sqq.) also contain halaka, but the chief contents are haggadic and homiletical.

[2] I. Abrahams points out to the writer that the rest is more summary. This difference is accounted for by the fact that Exod. xii. onwards and the rest of the Pentateuch have independent Midrashim: the Law proper was held by the Rabbis to begin at Exod. xii.

MIDSOMER NORTON, an urban district in the northern parliamentary division of Somersetshire, England, 12½ m. S.S.W. of Bath, on the Somerset & Dorset and the Great Western railways. Pop. (1901), 5809. The town is pleasantly situated in a hilly district, between two branches of the small river Somer. The church of St John the Baptist, principally Perpendicular, has in its tower three bells presented by Charles II. Both this town and the adjacent urban district of Radstock (pop. 3355) have a considerable trade in coal, which is mined in the vicinity. The coalfield extends northwestward towards Bristol, and is of great importance to the manufactures of that city.

MIDWIFE (Mid. Eng. *midwif*, *mydwyf* or *medewife*, from preposition *mid*, with, and *wife*, *i.e.* woman, in the sense of one who is *with* the mother, or from adjective *mid*, one who is the means of delivering the mother, a woman who assists other women in childbirth). As a class, midwives were recognized in Egypt in the time of the Jewish captivity. It was the universal practice in Europe until the middle of the 16th century, as it is to-day in the East, that women should be attended in confinement only by those of their own sex. From that period more attention was given to the practice of midwifery by the medical profession (see Obstetrics), while in continental Europe, towards the close of the 17th century, special schools were instituted for the proper training of midwives. But it was not until well on in the 19th century that any supervision or regulation was imposed on those who acted as midwives. Now in practically every European country midwives are under strict state control, they are required to undergo a course of thorough training, and their practice is carefully regulated by legislation.

In France midwives (*sages femmes*) are divided into a first and a second class. Those qualifying for both classes go through a two years' course of training and must qualify both in the theory and practice of midwifery, as well as in anatomy, physiology and pathology. A midwife of the first class has a superior status and can practise in any part of France, while those of the second class are restricted in their practice to the department for which the certificate was issued. Their qualifications allow them also to vaccinate and to prescribe certain antiseptic preparations. They are not allowed to use instruments and must call in a medical man in difficult cases. All cases must be reported to a central officer. In Spain midwives are allowed to practise on the result of an examination after studies covering at least four half-years. The diploma is issued by the director-general of public instruction. In Germany midwives are appointed, recognized and authorized by the state. They can conduct confinements independently and without the aid of a medical man. They must be provided with a certificate from the police authorities, and must reside in special districts assigned to them by the authorities. In Austria midwives before they are allowed to practise must pass a strict examination, after having followed a six months' course at one of the state schools of midwifery. They are subject to elaborate "instructions for midwives" issued from time to time by the ministry of the interior. In Italy a midwife must pass an examination and obtain a diploma from a recognized authority; but in order to obviate the difficulty which the poorer classes in the smaller communes would find in obtaining properly-authorized midwives, a certificate of permission to practise may be given to a certain number who have practised without the sanction of the law satisfactorily during a term of five years. These certificates are distributed by the prefect. In Russia matters pertaining to the appointment, transfer, dismissal and pay of midwives are under the charge of the medical department of the ministry of the interior. In each town of a province or region there is stationed one senior midwife and a number of junior midwives in proportion to the number of districts in the province. The examination of midwives and the issue of certificates of competency is carried out by the Medico-Chirurgical Academy and certain of the universities. A duly-licensed midwife, on presentation of her licence, is at once excluded from the tax-paying class to which she may have belonged. The general code of Russian laws lays down extensive rules for the carrying out of the duties of midwives. In Norway all midwives are licensed after examination and are under the control and inspection of the board of health. Provision is made for infirm and aged midwives. They are usually paid by the parish, but also receive fees according to the means of the person attended. In Sweden a certificate of competency and of having passed an examination does not give a midwife a right to practise until a note has been made on the certificate that the oath of office has been duly taken. All midwives are under the control of the board of health. When a midwife takes up her residence in a parish, or moves from one place to another, she must announce the fact within a month to the nearest appointed doctor and exhibit her certificate. In towns a midwife must put up a notice board outside her residence; she must not absent herself from home without leaving word as to where she may be found and at what hour she will probably return. In the country a midwife may be paid out of the poor rate. In Denmark, also, midwives are recognized by the state, and the practise of midwifery is almost entirely in the hands of women. In Holland a certain number of candidates are given free training by the state in return for their practising midwifery in scattered country districts at a fixed salary. Many of the states of the United States have also passed laws for the registration of midwives.

In England alone there was no regulation of any kind so late as 1902. Any person, however ignorant and untrained, could describe herself as a midwife and practise for gain. Several societies made continuous efforts towards the close of the 19th century to obtain legislation. A select committee on midwives' registration reported in 1892 that the evidence they had taken showed that there was at the time "serious and unnecessary loss of life and health and permanent injury to both mother and child in the treatment of childbirth, and that some legislative provision for improvement and regulation was desirable." A similar committee reported to the same effect in 1893. Eventually a bill was drafted with the object of securing the examination and registration of midwives, but, although introduced several times into the House of Commons, it was not successful until 1902. The Midwives Act 1902 forbids any woman after the 1st of April 1905 to call herself "midwife" without a certificate, or to act as a midwife for gain without a certificate after the 1st of April 1910. Existing midwives (those who held certificates in midwifery from certain recognized institutions, or produced satisfactory evidence at the passing of the act that they had been for at least one year in bona fide practice as midwives, and bore good characters) were allowed to claim certificates within two years from the 1st of April 1903. The act created a central midwives' board, whose duties are, *inter alia*, to regulate the issue of certificates and the conditions of admission to the roll of midwives; to regulate the course of training and conduct of examinations; to regulate, supervise and restrict within due limits the practice of midwives; to publish annually a roll of duly certified midwives; to remove from the roll the name of any midwife who disobeys the rules and regulations laid down from time to time; to issue and cancel certificates, &c. There is an appeal to the High Court of Justice against removal of a name, but the appeal must be made within three months. Local authorities are required to exercise supervision over the midwives within their area; they must investigate charges of malpractice, negligence or misconduct; exercise the power of suspension and report convictions. They must supply the central board with the names and addresses of those practising within their area, and notify any death. The local authority must appoint a committee to carry out its powers or duties under the act, and may, if it think fit, delegate its powers to a lesser local authority, such as a district council. The act provides for penalties for obtaining a certificate by false representation or for wilful falsification of the roll. The act does not apply to Ireland or Scotland. (T. A. I.)

MIERES, a town of northern Spain, in the province of Oviedo, 12 m. by rail S.E. of Oviedo, on the river Caudal, a tributary of the Nalon. Pop. (1900), 18,083. Mieres is the chief town of a mountainous, fertile and well-wooded region in which coal, iron, and copper are extensively mined and sulphur and cinnabar are obtained in smaller quantities. The town contains large iron foundries and chemical works, and has an active trade in fruit, cider, timber and live stock.

MIEREVELT (Miereveld, or Mireveldt), **MICHIEL JANSZ VAN** (1567–1641), Dutch painter, was born at Delft, the son of a goldsmith, who apprenticed him to the copperplate engraver J. Wierix. He subsequently became a pupil of Willem Willemz and Augusteyn of Delft, until Anthonie van Montfoort (Blocklandt), who had seen and admired two of Mierevelt's early engravings, "Christ and the Samaritan" and "Judith and Holofernes," invited him to enter his school at Utrecht. Devoting himself first to still life, he eventually took up portraiture, in which he achieved such success that the many commissions entrusted to him necessitated the employment of numerous assistants, by whom hundreds of portraits were turned out in factory fashion. The works that can with certainty be ascribed to his own brush are remarkable for their sincerity, severe drawing and harmonious colour, but comparatively few of the two thousand or more portraits that bear his name are wholly his own handiwork. He settled down in his native town, but went frequently to The Hague, where he entered the gild of St Luke in 1625. So great was his reputation that he was patronized by royalty in many countries and acquired great wealth. The king of Sweden and the count palatine of Neuburg presented him with golden chains, Archduke Albrecht gave him a pension, and Charles I. vainly endeavoured to induce him to visit the English court. Though Mierevelt is chiefly known as a portrait painter, he also executed some mythological pieces of minor importance. Many of his portraits have been reproduced in line by the leading Dutch engravers of his time. He died at Delft on the 27th of June 1641.

The Ryks Museum in Amsterdam has the richest collection of Mierevelt's works, chief of them being the portraits of William, Philip William, Maurice, and Frederick Henry of Orange, and of the count palatine Frederick V. At The Hague Museum are the portraits of four princes of the house of Orange, of Frederick V., king of Bohemia, and of Louise de Coligny as a widow. Other portraits by him are at nearly all the leading continental galleries, notably at Brunswick (3), Gotha (2), Schwerin (3), Munich (2), Paris (Louvre, 3), Dresden (4), Berlin (2), and Darmstadt (3). The town hall of Delft also has numerous examples of his work.

Many of his pupils and assistants rose to fame. The most gifted of them were Paulus Moreelse and Jan van Ravesteyn. His sons Pieter (1596–1623) and Jan (d. 1633), and his son-in-law Willem Jacobz Delff, probably painted many of the pictures which go under his name. His portrait was painted by Van Dyck and engraved by Delff.

MIERIS, the name of a family of artists who practised painting at Leiden for three generations in the 17th and 18th centuries.

1. Frans van Mieris, the elder (? 1635–1681), son of Jan van Mieris, a goldsmith and diamond setter, was born, according to Houbraken, at Leiden on the 16th of April 1635, and died there on the 12th of March 1681. His father wished to train him to his own business, but Frans preferred drawing to chasing, and took service with Abraham Torenvliet, a glazier who kept a school of design. In his father's shop he became familiar with the ways and dress of people of distinction. His eye was fascinated in turn by the sheen of jewelry and stained glass; and, though he soon gave up the teaching of Torenvliet for that of Gerard Douw and Abraham van den Tempel, he acquired a manner which had more of the finish of the exquisites of the Dutch school than of the breadth of the disciples of Rembrandt. It should be borne in mind that he seldom chose panels of which the size exceeded 12 to 15 in., and whenever his name is attached to a picture above that size we may surely assign it to his son Willem or to some other imitator. Unlike Gerard Douw when he first left Rembrandt, or Jan Steen when he started on an independent career, Mieris never ventured to design figures as large as life. Characteristic of his art in its minute proportions is a shiny brightness and metallic polish. The subjects which he treated best are those in which he illustrated the habits or actions of the wealthier classes; but he sometimes succeeded in homely incidents and in portrait, and not unfrequently he ventured on allegory. He repeatedly painted the satin skirt which Ter Borch brought into fashion, and he often rivalled Ter Borch in the faithful rendering of rich and highly-coloured woven tissues. But he remained below Ter Borch and Metsu, because he had not their delicate perception of harmony or their charming mellowness of touch and tint, and he fell behind Gerard Douw, because he was hard and had not his feeling for effect by concentrated light and shade. In the form of his composition, which sometimes represents the framework of a window enlivened with greenery, and adorned with bas-reliefs within which figures are seen to the waist, his model is certainly Gerard Douw.

It is a question whether Houbraken has truly recorded this master's birthday. One of his best-known pieces, a party of ladies and gentlemen at an oyster luncheon, in the Hermitage at St Petersburg, bears the date of 1650. Celebrated alike for composition and finish, it would prove that Mieris had reached his prime at the age of fifteen. Another beautiful example, the "Doctor Feeling a Lady's Pulse" in the gallery of Vienna, is dated 1656; and Waagen, in one of his critical essays, justly observes that it is a remarkable production for a youth of twenty-one. In 1657 Mieris was married at Leiden in the presence of Jan Potheuck, a painter, and this is the earliest written record of his existence on which we can implicitly rely. Of the numerous panels by Mieris, twenty-nine at least are dated—the latest being an allegory, long in the Ruhl collection at Cologne, illustrating what he considered the kindred vices of drinking, smoking and dicing, in the year 1680.

Mieris had numerous and distinguished patrons. He received valuable commissions from Archduke Leopold, the elector-palatine, and Cosimo III., grand-duke of Tuscany. His practice was large and lucrative, but never engendered in him either carelessness or neglect. If there be a difference between the painter's earlier and later work, it is that the former was clearer and more delicate in flesh, whilst the latter was often darker and more livid in the shadows. When he died his clients naturally went over to his son Willem, who in turn bequeathed his painting-room to his son Frans. But neither Willem nor Frans the younger equalled Frans the elder.

2. Willem van Mieris (1662–1747), son of Frans. His works are extremely numerous, being partly imitations of the paternal subjects, or mythological episodes, which Frans habitually avoided. In no case did he come near the excellence of his sire.

3. Frans van Mieris, the younger (1689–1763), also lived on the traditions of his grandfather's studio.

The pictures of all the generations of the Mieris family were successfully imitated by A. D. Snaphaan, who lived at Leipzig and was patronized by the court of Anhalt-Dessau. To those who would study his deceptive form of art a visit to the collection of Wörlitz near Dessau may afford instruction.

MIFFLIN, THOMAS (1744–1800), American soldier and politician, was born in Philadelphia, Pennsylvania, on the 10th of January 1744, of Quaker parentage. He graduated at the college of Philadelphia (now the university of Pennsylvania) in 1760. As a member of the Pennsylvania house of representatives in 1772–1775, he was an ardent Whig, and in 1774 was a member of the first Continental Congress. After the outbreak of the War of Independence he devoted himself chiefly to the enlisting and drilling of troops, and was chosen major of a regiment. In June 1775 he entered the continental service as Washington's first aide-de-camp, and in August was chosen quartermaster-general. He became a brigadier-general in May 1776 and a major-general in February 1777. On the 5th of June 1776 he was succeeded as quartermaster-general by Stephen Moylan. Moylan, however, proved incompetent, and Mifflin resumed the office on the 1st of October. In the autumn of 1777 Mifflin was a leader in the obscure movement known as the Conway Cabal, the object of which was to replace Washington by General Horatio Gates. On the ground of ill health Mifflin tendered his resignation on the 8th of October, and on the 7th of November Congress accepted his resignation as quartermaster-general, but continued him in rank as major-general without pay. On the same day he was appointed a member of the new board of war, and on the following day was asked to continue as quartermaster-general until his successor should be appointed. On the 21st of November he urged before the old board of war and ordnance that Gates should be made president of the new board of war "from a conviction that his military skill would suggest reformations in the different departments of the army essential to good discipline, order and economy, and that his character and popularity in the army would facilitate the execution of such reformations when adopted by Congress." The attacks on Washington failed, and in March 1778 Mifflin was finally superseded as quartermaster-general by General Nathanael Greene. In October of the same year he was removed from the board of war. The sufferings of the troops at Valley Forge having been charged to his mismanagement as quartermaster-general, Congress, in June 1778, ordered an investigation; but before this inquiry had proceeded far, Congress granted him $1,000,000 to settle all claims against the office during his administration. In February 1779 he resigned his commission as major-general. During the war his eloquence was repeatedly of assistance to Congress in recruiting soldiers. He was a delegate in Congress in 1782–1784, and from November 1783 to November 1784 was president, in which office he received Washington's resignation of the command of the army and made a congratulatory address. In 1785–1788 he was speaker of the Pennsylvania general assembly (then consisting of only one house); he was a member of the Federal Constitutional Convention of 1787, and president of the state supreme executive council (or chief executive officer of the state) in 1788–1790. He was president of the Pennsylvania Constitutional Convention of 1789–1790; was the first governor of the state, from 1790 to 1799, after the adoption of the new state constitution; and during the Whisky Insurrection assumed personal command of the Pennsylvania militia. Towards the close of his last term as governor he was elected a member of the state assembly, but died during the first session, at Lancaster, on the 20th of January 1800.

See William Rawle, "Sketch of the Life of Thomas Mifflin," in *Memoirs of the Historical Society of Pennsylvania* (vol. 2, part 2, Philadelphia, 1830); and J. H. Merrill, *Memoranda relating to the Mifflin Family* (Philadelphia, 1890).

MIGNARD, PIERRE (1610–1695), called—to distinguish him from his brother Nicholas—Le Romain, French painter, was born at Troyes in 1610, and came of a family of artists. In 1630 he left the studio of Simon Vouet for Italy, where he spent twenty-two years, and made a reputation which brought him a summons to Paris. Successful with his portrait of the king, and in favour with the court, Mignard pitted himself against Le Brun, declined to enter the Academy of which he was the head, and made himself the centre of opposition to its authority. The history of this struggle is most important, because it was identical, as long as it lasted, with that between the old gilds of France and the new body which Colbert, for political reasons, was determined to support. Shut out, in spite of the deserved success of his decorations of the cupola of Val de Grace (1664), from any great share in those public works the control of which was the attribute of the new Academy, Mignard was chiefly active in portraiture. Turenne, Molière, Bossuet, Maintenon (Louvre), La Vallière, Sévigné, Montespan, Descartes (Castle Howard), all the beauties and celebrities of his day, sat to him. His readiness and skill, his happy instinct for grace of arrangement, atoned for want of originality and real power. With the death of Le Brun (1690) the situation changed; Mignard deserted his allies, and succeeded to all the posts held by his opponent. These late honours he did not long enjoy; in 1695 he died whilst about to commence work on the cupola of the Invalides. His best compositions have been engraved by Audran, Edelinck, Masson, Poilly and others.

MIGNE, JACQUES PAUL (1800–1875), French priest and publisher, was born at St Flour, Cantal, on the 25th of October 1800. He studied theology at Orleans, was ordained priest in 1824 and placed in charge of the parish of Puiseaux, in the diocese of Orleans. In 1833 he went to Paris, and started *L'Univers religieux*, which afterwards became Louis Veuillot's ultramontane organ. On severing his connexion with the paper three years later, he opened at Petit Montrouge, near Paris, the great publishing house which brought out in rapid succession numerous religious works at popular prices. The best known of these are: *Scripturae sacrae cursus completus*, and *Theologiae cursus* (each in 28 vols., 1840–1845); *Collection des auteurs sacrés* (100 vols., 1846–1848); *Encyclopédie théologique* (171 vols., 1844–1866); *Patrologiae cursus completus*, Latin series in 221 vols. (1844–1855; 2nd edition, 1878 seq.); Greek series, first published in Latin (85 vols., 1856–1861); with Greek text and Latin translation (165 vols., 1857–1866). Unfortunately these editions, brought out in great haste and often edited by superficial scholars, do not come up to the requirements of modern criticism. By far the most noteworthy is the Patrology, which was superintended by the learned Benedictine J. B. Pitra. Its vast scope leaves it still unique and valuable, where other editions of special works do not exist. The indices in 3 vols. are arranged so that one may easily find any reference in the patristic writings. In February 1868 a great fire destroyed the whole of Migne's printing premises, but he established a new house in Paris, which was purchased in 1876 by the publishers Garnier Frères, who still own all the works brought out by Migne. He died in Paris on the 25th of October 1875.

For a more complete account of Migne's life, see the article in the *Catholic Encyclopedia* (New York, 1906 seq.).

MIGNET, FRANÇOIS AUGUSTE ALEXIS (1796–1884), French historian, was born at Aix in Provence on the 8th of May 1796, and died at Paris on the 24th of March 1884. His father, a Vendean by birth, was an ordinary locksmith, who enthusiastically accepted the principles of the French Revolution and roused in his son the same love for liberal ideas. François had brilliant successes when studying at Avignon in the *lycée* where he was afterwards professor (1815); he returned to Aix to study law, and in 1818 was called to the bar, where his eloquence would have ensured his success had he not preferred the career of an historian. His abilities were shown in an *Éloge de Charles VII.*, which was crowned by the Académie de Nîmes in 1820, and a memoir on *Les Institutions de Saint Louis*, which in 1821 was crowned by the Académie des Inscriptions et Belles Lettres. He then went to Paris, where he was soon joined by his friend and compatriot, Adolphe Thiers, the future president of the French republic. He was introduced by J. A. Manuel, formerly a member of the Convention, to the Liberal paper, *Courrier français*, where he became a member of the staff which carried on a fierce pen-and-ink warfare against the Restoration. He acquired his knowledge of the men and intrigues of the Napoleonic epoch from Talleyrand. He wrote a *Histoire de la révolution française* (1824) in support of the Liberal cause. It was an enlarged sketch, prepared in four months, in which more stress was laid on fundamental theories than on the facts, which are more rigidly linked together than their historical sequence warrants. In 1830 he founded the *National* with Thiers and Armand Carrel, and signed the journalists' protest against the *Ordonnances de juillet*, but he refused to accept his share of the spoil after his party had won. He was satisfied with the modest position of director of the archives at the Foreign Office, where he stayed till the revolution of 1848, when he was dismissed, and retired permanently into private life. He had been elected a member of the Académie des Sciences Morales et Politiques, re-established in 1832, and in 1837 was made the permanent secretary; he was also elected a member of the Académie Française in 1836, and sought no further honours. He was well known in fashionable circles, where his witty conversation and his pleasant manners made him a favourite. The greater part of his time was, however, given to study and to his academic duties. Eulogies on his deceased fellow-members, the Academy reports on its work and on the prizes awarded by it, which it was part of Mignet's duty as secretary to draw up, were literary fragments thoroughly appreciated by connoisseurs. They were collected in Mignet's *Notices et portraits*. He worked slowly when in his study, and willingly lingered over research. With the exception of his description of the French Revolution, which was chiefly a political manifesto, all his early works refer to the middle ages—*De La féodalité, des institutions de Saint Louis et de l'influence de la législation de ce prince* (1822); *La Germanie au viii*^{e} *et au ix*^{e} *siècle, sa conversion au christianisme, et son introduction dans la société civilisée de l'Europe occidentale* (1834); *Essai sur la formation territoriale et politique de la France depuis la fin du xi*^{e} *siècle jusqu'à la fin du xv*^{e} (1836); all of these are rough sketches showing only the outlines of the subject. His most noted works are devoted to modern history. For a long time he had been taken up with a history of the Reformation, but only one part of it, dealing with the Reformation at Geneva, has been published. His *Histoire de Marie Stuart* (2 vols., 1851) is well worth reading; the author made liberal use of some important unpublished documents, taken for the greater part from the archives of Simancas. He devoted some volumes to a history of Spain, which had a well-deserved success—*Charles Quint, son abdication, son séjour, et sa mort au monastère de Yuste* (1845); *Antonio Perez et Philippe II.* (1845); and *Histoire de la rivalité de François I. et de Charles Quint* (1875). At the same time he had been commissioned to publish the diplomatic acts relating to the War of the Spanish Succession for the *Collection des documents inédits*; only four volumes of these *Négociations* were published (1835–1842), and they do not go further than the peace of Nijmwegen; but the introduction is celebrated, and Mignet reprinted it in his *Mélanges historiques.*

See the eulogy of Mignet by Victor Duruy, delivered on entering the Académie Française on the 18th of June 1885, and the notice by Jules Simon, read before the Académie des Sciences Morales et Politiques on the 7th of November 1885.

MIGNON, ABRAHAM (1640–1697), Dutch painter, was born at Frankfort. His father, a merchant, placed him under the still-life painter Jacob Merrel, by whom he was taken to Holland about 1660. He then worked under de Heem at Utrecht, where in 1675 he married the daughter of the painter Cornelis Willaerts. Sibylle Merian (1647–1717), daughter of the engraver Matthew Merian, became his pupil and achieved distinction as a flower painter. He died at Wetzlar. Mignon devoted himself almost exclusively to flowers, fruit, birds and other "still life," though at times he also attempted portraiture. His flower pieces are marked by careful finish and delicate handling. His favourite scheme was to introduce red or white roses in the centre of the canvas and to set the whole group of flowers against a dark background. Nowhere can his work be seen to better advantage than at the Dresden Gallery, which contains fifteen of his paintings, twelve of which are signed. Six of his pictures are at the Louvre, four at the Hermitage, and other examples are to be found at the museums of Amsterdam, The Hague, Rotterdam, Brussels, Munich, Karlsruhe, Brunswick, Cassel, Schwerin, Copenhagen and Turin.

MIGNONETTE, or MIGNONNETTE (*i.e.* "little darling"), the name given to a popular garden flower, the *Reseda odorata* of botanists, a "fragrant weed," as Cowper calls it, highly esteemed for its delicate but delicious perfume. The mignonette is generally regarded as being of annual duration, and is a plant of diffuse decumbent twiggy habit, scarcely reaching a foot in height, clothed with bluntish lanceolate entire or three-lobed leaves, and bearing longish spikes—technically racemes—of rather insignificant flowers at the ends of the numerous branches and branchlets. The plant thus naturally assumes the form of a low dense mass of soft green foliage studded over freely with the racemes of flowers, the latter unobtrusive and likely to be overlooked until their diffused fragrance compels attention. It is probably a native of North Africa and was sent to England from Paris in 1742; and ten years later it appears to have been sent from Leiden to Philip Miller at Chelsea. Though originally a slender and rather straggling plant, there are now some improved garden varieties in which the growth is more compact and vigorous, and the inflorescence bolder, though the odour is perhaps less penetrating. The small six-petalled flowers are somewhat curious in structure: the two upper petals are larger, concave, and furnished at the back with a tuft of club-shaped filaments, which gives them the appearance of being deeply incised, while the two lowest petals are much smaller and undivided; the most conspicuous part consists of the anthers, which are numerous and of a brownish red, giving the tone of colour to the inflorescence. In the varieties named Golden Queen and Golden Machet the anthers have a decided tint of orange-yellow, which imparts a brighter golden hue to the plants when in blossom. A handsome proliferous or double-flowered variety has also been obtained, which is a very useful decorative plant, though only to be propagated by cuttings; the double white flowers grow in large massive panicles (proliferous racemes), and are equally fragrant with those of the ordinary forms.

What is called tree mignonette in gardens is due to the skill of the cultivator. Though practically a British annual, as already noted, since it flowers abundantly the first season, and is utterly destroyed by the autumnal frosts, and though recorded as being annual in its native habitat by Desfontaines in the *Flora Atlantica*, the mignonette, like many other plants treated in England as annuals, will continue to grow on if kept in a suitable temperature. Moreover, the life of certain plants of this semi-annual character may be prolonged into a second season if their flowering and seeding are persistently prevented. In applying these facts to the production of tree mignonette, the gardener grows on the young plants under glass, and prevents their flowering by nipping off the blooming tips of the shoots, so that they continue their vegetative growth into the second season. The young plants are at first supported in an erect position, the laterals being removed so as to secure clean upright stems, and then at the height of one or two feet or more, as may be desired, a head of branches is encouraged to develop itself. In this way very large plants can be produced.

For ordinary purposes, however, other plans are adopted. In the open borders of the flower garden mignonette is usually sown in spring, and in great part takes care of itself; but being a favourite either for window or balcony culture, and on account of its fragrance a welcome inmate of town conservatories, it is also very extensively grown as a pot plant, and for market purposes with this object it is sown in pots in the autumn, and thinned out to give the plants requisite space, since it does not transplant well, and it is thereafter specially grown in pits protected from frosts, and marketed when just arriving at the blooming stage. In this way hundreds of thousands of pots of blooming mignonette are raised and disposed of year by year.

In classifying the odours given off by plants Rimmel ranks the mignonette in the class of which he makes the violet the type; and Fée adopts the same view, referring it to his class of "iosmoids" along with the violet and wallflower.

The genus *Reseda* contains about fifty species, natives of Europe and West Asia. *R. luteola*, commonly called dyer's-weed and weld, yields a valuable yellow dye. *R. alba* is a fine biennial about 2 ft. high, with erect spikes of whitish flowers.

MIGNONS, LES. In a general sense the French word *mignon* means "favourite," but the people of Paris used it in a special sense to designate the favourites of Henry III. of France, frivolous and fashionable young men, to whom public malignity attributed dissolute morals. According to the contemporary chronicler Pierre de l'Estoile, they made themselves "exceedingly odious, as much by their foolish and haughty demeanour, as by their effeminate and immodest dress, but above all by the immense gifts the king made to them." The Guises appear to have stirred up the ill will of the Parisians against them. From 1576 the *mignons* were attacked by popular opinion, and historians accredited without proof the scandalous stories of the time. The best known of the *mignons* were the dukes of Joyeuse and of Épernon.

MIGNOT, CLAUDINE FRANÇOISE [commonly called MARIE] (*c.* 1617–1711), French adventuress, was born near Grenoble, at Meylan. At the age of sixteen she attracted the notice of the secretary of Pierre des Portes d'Amblérieux, treasurer of the province of Dauphiny, and Amblérieux promised to promote their marriage. He married the girl himself, however, and left her his fortune. His will was disputed by his family, and Claudine went to Paris in 1653 to secure its fulfilment. She sought the protection of François de l'Hôpital, marshal of France, then a man of seventy-five. He married her within a week of their first meeting, and after seven years of marriage died leaving her part of his estate. By a third and morganatic marriage in 1672 with John Casimir, ex-king of Poland, a few weeks before his death, she received a third fortune. Immediately on her marriage with Amblérieux she had begun to educate herself, and her wealth and talents assured her a welcome in Paris. She retired in her old age to a Carmelite convent in the city, where she died on the 30th of November 1711.

Her history, very much modified, was the subject of a play by Bayard and Paul Duport, *Marie Mignot* (1829).

MIGRATION. Under this title will be considered movements of men with intention of changing their residence or domicile. Such migration (Lat. *migrare*) may be either external—that is, from one country to another, including emigration from mother country to colony; or it may be internal—that is, within the limits of a single country. Under external migration are comprised *emigration* and *immigration*, denoting simply direction from and to. The emigrants are at the same time the immigrants; that is, the material of the movement is the same, but the effect upon the country giving up and the country receiving the migrant requires separate treatment. Hence it is proper to separate emigration from immigration. Temporary migration, or travel for purposes of business, enterprise or pleasure, will be considered only incidentally, and because in some cases it is difficult to distinguish between such movements and permanent migration.

Migration in general may be described as a natural function of social development. It has taken place at all times and in the greatest variety of circumstances. It has been tribal, national, class and individual. Its causes have been political, economic, religious, or mere love of adventure. Its causes and results are fundamental for the study of ethnology (formation and mixture of races), of political and social history (formation of states and survival of institutions), and of political economy (mobility of labour and utilization of productive forces). Under the form of conquest it makes the grand epochs in history (*e.g.* the fall of the Roman Empire); under the form of colonization it has transformed the world (*e.g.* the settlement of America); under free initiative it is the most powerful factor in social adjustment (*e.g.* the growth of urban population). It must suffice here to indicate the character of the principal movements in the past, and then describe certain aspects of modern migration. The early movements may be grouped as follows: (*a*) Prehistoric migrations. Among savage and nomadic nations the whole tribe often moves into new territory, either occupying it for the first time or exterminating or driving out the indigenous inhabitants. We have only vague knowledge of these early movements, laboriously gleaned from archaeology, anthropology and philology. The cause has been commonly said to be the pressure of population on the food-supply. A more probable explanation is the love of booty and the desire of the stronger to take possession of the lands of the weaker. (*b*) Greek and Roman colonization. Both of these ancient civilizations extended their influence through migration of individual families and the planting of colonies. The motive seems to have been primarily commercial—that is, the love of gain. It may have been partly a sort of "swarming" process, caused by pressure of population at home. In some cases it had a political motive, as the planting of military colonies or providing new homes for the proletariat. The consequences were of course momentous. (*c*) The German Conquest. Beginning about the 5th century, the Roman empire was overthrown by German tribes from the north of the river Danube and east of the river Rhine. This *Völkerwanderung*, as it is called by German historians, again transformed the face of Europe, resulting in the establishment of independent kingdoms and a great mixture of races and institutions. It was coincident with the building-out of the feudal system. The conquered in many cases could be left as serfs and tillers of the soil, while the conquerors seized the higher positions of administration and power. (*d*) The later middle ages saw many minor migratory movements, such as those accompanying the crusades, the pushing of German colonization among the Slavs, and the introduction of Flemish weavers into England. The religious reformation caused a considerable amount of expatriation, culminating in the expulsion of the Huguenots from France. (*e*) The period of discovery and colonization opened up a new era for migration. The first expeditions were for adventure and booty, especially the discovery of gold and silver. Then came the establishment of commercial posts or factories for the purposes of trade. Finally came colonization proper—that is, the settlement of new countries by Europeans intending to remain there permanently, but still retaining their connexion with the mother country. This meant the opening up of the world to commerce and the extension of European civilization to vast areas formerly peopled by savages or half-civilized peoples. It meant a great outlet for the spirit of enterprise and adventure, relief from over-population, an enormous increase in wealth and power, and a struggle for supremacy among the nations of Europe. Colonization and colonial policy excited immense attention in Europe; and this extended into the 19th century (*e.g.* E. G. Wakefield's plans for colonization, and the various colonization societies of modern times). The colonial policy proper was broken down by the revolt of the North American colonies from Great Britain, and later of Mexico and Central and South America from Spain. (*f*) The movement of population, however, has continued under the form of emigration. This movement is characterized firstly by its magnitude; secondly, by the fact that the emigrant changes his political allegiance, for by far the greater part of modern emigration is to independent countries, and even where it is to colonies the colonies are largely self-governing and self-regarding; and thirdly, it is a movement of individuals seeking their own good, without state direction or aid. This is 20th-century emigration, differing from all preceding forms and having an importance of its own.

Statistics of Emigration.—The direction of the modern movement is from Europe to America, Australia and South Africa, as shown in the following table:—

Emigration from Certain States of Europe, 1890–1905.[1]

Year.	Italy.	France.	Belgium.	Holland.	Spain.[2]	Portugal.	Austria-Hungary.	Switzer-land.	Germany.
1890	115,595	20,560	2976	3526	37,025	28,945	74,002	6693	97,103

---

[1] The figures relate only to the emigrants of each nationality emigrating from their own country to countries outside of Europe.

[2] Exclusive of emigrants to Spanish colonies.

[3] Russian emigrants from German ports.

Since 1820 over twenty million persons have emigrated from Europe to countries beyond the sea. The greater part of this emigration has been to the United States of North America. The history of emigration is well shown in the following table of emigration from Great Britain and Ireland. Down to 1853 the figures include all emigrants from British ports; after 1853 emigrants of British and Irish origin only.

Emigration from Great Britain and Ireland, 1815–1905.

Statistics of Immigration.—The statistics of the United States are the most important and the most complete. The statistics since 1820 are shown in the following table:—

Immigration into the United States, 1820–1905.

Decade ending 30th June.	Aggregate Arrivals.	Annual Average.
1830	143,439	14,343
1840	599,125	59,912
1850	1,713,251	171,325
1860	2,598,214	259,821
1870	2,314,824	231,482
1880	2,812,191	281,219
1890	5,246,613	524,661
1900	3,844,422	384,442
1901–1905 . . .	3,833,076	766,615
Total . . .	23,116,501	

Prior to 1820 there was no official record of immigration, but it is estimated that the total number of immigrants from the close of the Revolutionary War was 250,000. During the decade from 1820 to 1830 the movement was very moderate. From 1830 to 1840 it steadily increased, but never reached 100,000 per annum. In 1846 came the Irish potato famine, and an enormous emigration began, followed by a very large German emigration from similar causes. The Civil War of the United States interrupted the movement, but it was speedily resumed on an enlarged scale owing especially to the improved means of ocean transportation. It culminated in the decade 1880–1890, and declined after the commercial crisis of 1893. Later there was another increase.

The relative movement of nationalities is best presented by the statistics of the United States. The nationality (country of origin of immigrants coming to the United States, 1871–1895) is shown in the following table:—

Nationality of Immigration to the United States.

	25 Years 1871–1895.	Per cent. of Total Immigration
Anglo-Saxons, Celts, and Welshmen—

[1] Of these, 77,409 went to the Cape of Good Hope and Natal.
[2] Of these, 152,797 went to the Cape of Good Hope and Natal.
[3] Of these, 69,052 went to the Cape of Good Hope and Natal.

A very important transformation has taken place in the proportionate number coming from different countries during the last half of the 19th century. At first the Irish and Germans were most prominent. Of later years, the Italians, Czechs, Hungarians and Russians were, as will be seen from the following table, numerously represented.

Nationality of Immigrants to the United States, 1901–1905.

	Number.	%
Austria-Hungary	944,239	25·0
Belgium	16,884	0·44
Bulgaria, Servia and Montenegro	6,637	0·17
Denmark	33,968	0·9
France	31,419	0·8
Germany	176,995	4·6
Greece	49,962	1·3
Holland	18,501	0·48
Italy	959,768	25·0
Norway	103,065	2·7
Portugal	30,532	0·8
Rumania	35,185	0·4
Russia	658,735	17·0
Spain	10,243	0·27
Sweden	154,607	4·0
Switzerland	17,820	0·46
Turkey	10,909	0·3
United Kingdom—		
England	155,343	4·0
Ireland	184,096	4·8
Scotland	38,842	1·0
Wales	6,972	0·18
All other European countries	216	0·006
Total	3,645,018	95

The following table shows the relative number of different nationalities represented in the immigration to the United States:—

Country.	1861–70.	1871–80.	1881–90.	1891–1900.
	%	%	%	%
Great Britain	24·5	16·4	12·5	7·5
Ireland	18·8	15·5	12·5	10·0
Germany	34·0	25·5	27·7	14·0
Austria-Hungary	0·3	2·6	6·7	16·0
Norway and Sweden	4·7	7·5	10·8	8·6
Russia and Poland	0·2	1·9	5·1	14·0
Italy	0·5	2·0	5·9	18·0

Sex and Age.—Of all the immigrants (1871–1895), 61·25 % were males and 38·75 % were females.

This percentage remains fairly constant, but the proportion differs somewhat among different nationalities. The following table shows the proportions for 1905:—

	Males.	Females.
Austria-Hungary	207,034	77,933
France	5,574	3,889
Germany	21,586	15,357
Holland	3,082	1,758
Italy	216,268	51,273
Russia	111,795	66,065
Sweden and Norway	29,907	18,105
United Kingdom—		
England	29,993	18,160
Ireland	18,754	18,890
Scotland	9,264	5,022

The immigrants were in the most vigorous period of life, few children and few old people, as shown in the following table:—

Ages of Immigrants to the United States, 1881–1890.

Country of Origin.	Under 15.		From 15 to 40.		Over 40 years.	
	Number.	Per cent.	Number.	Per cent.	Number.	Per cent.
Germany	386,934	26·6	904,002	62·2	162,034	11·2
Ireland	92,308	14·1	515,089	78·6	48,085	7·3
England	151,315	23·5	420,303	65·2	73,062	11·3
Sweden and Norway	104,254	18·3	414,609	73·0	49,499	8·7
Italy	47,603	15·3	212,475	69·2	47,771	15·5
Russia (including Poland)	65,427	24·7	174,754	65·9	24,907	9·4
Austria	50,027	22·1	149,909	66·3	26,109	11·6
Scotland	36,192	24·2	97,819	65·2	15,858	10·6
Hungary	18,785	14·7	95,635	74·9	13,261	10·4

Occupation.—The immigrants are for the most part unskilled labourers. The statistics for the United States show the following figures for the years 1881–1890:—

Occupation of Immigrants to the United States.

	Males.	Females.	Total.
Professional	25,257	1,749	27,006
Skilled	514,552	25,859	540,411
Miscellaneous	1,833,325	245,810	2,079,135
Not stated	73,327	42,830	116,157
Without occupation	759,450	1,724,454	2,483,904
Total	3,205,911	2,040,702	5,246,613

Those "without occupation" are mostly women and children. The "miscellaneous" are day labourers. It is probable that about 20 % of the adult males are "skilled."

Immigration to Other Countries.—In no other country is immigration conducted on so important a scale as in the United States. The statistics are very imperfect. The main figures have already been given in the table of emigration. Australia has an annual immigration of about 250,000, mostly of British origin. This is offset by a very heavy emigration, which sometimes exceeds the immigration in certain of the states. The immigration to Canada for the year 1905 was put down as 146,266, but a portion of this consisted of immigrants passing through to the United States. Brazil has had a large immigration (in 1895 equal to 169,524, but in 1904 only 12,447). The Argentine is credited with an immigration in 1905 of 177,117, and Uruguay with an immigration in 1903 of 6247. In all the South American immigration the countries principally represented are those of southern Europe, especially Italy. The majority of the immigrants are adult males and farm labourers.

Balance of Emigration and Immigration.—Even in the case of emigration from Europe to countries beyond the seas there is some return movement. Emigrants who have been successful in business return in order to end their days in the old country. Those who have not succeeded return in order to be cared for by friends and relatives, or simply from home-sickness. Thus, for Great Britain and Ireland, while the emigration of persons of British and Irish origin was, in 1905, 262,077, the immigration of persons of the same category was 122,712, leaving a net emigration of only 139,365. In the United States' statistics we cannot distinguish in the outgoing passenger movement emigrants from other persons. But if for a period of years we take the total inward passenger movement and subtract from it the total outward passenger movement, we ought to have the net immigration. By this method we arrive at the conclusion that while the gross immigration during the five years 1901–1905 was 3,833,076, the net immigration was only 1,779,976, showing an outward movement of 273,134, or about 7·12 % of the total number of immigrants.

Temporary Emigration.—In many European countries there is not only emigration beyond seas, but a very considerable movement to neighbouring countries in search of work, and generally with the intention of returning. Thus in Italy, the "permanent" emigration (*i.e.* to countries beyond seas) numbered, in 1905, 447,083; the "temporary" emigration to European or Mediterranean countries amounted to 279,248. This temporary emigration is strongest in the spring, and consists principally of adult males (agriculturists, farm and day labourers, bricklayers and masons) in search of work. It resembles somewhat the movement of Irish labourers into Great Britain at harvest time. It is notorious that the Italians who emigrate to the United States largely return.

Effects of Emigration.—There are two views with regard to emigration: one unfavourable, viz., that it is a drain on population, reducing its economic strength and disturbing social and political relations; the second looking upon it as a relief from over-population and a congested labour market. As a matter of fact, emigration has not succeeded in diminishing the population of Europe, which, on the contrary, doubled during the 19th century. The one great exception is Ireland, where population declined from 8,175,124 in 1841 to 4,458,745 in 1901. From 1851 to 1901 the total emigration from Ireland was 3,881,246 or 72·5 % of the average population. Emigration, by carrying off the young men and women, also reduced the Irish marriage and birth-rates, which were almost the lowest in Europe. But hitherto the countries of strongest emigration (England, Germany, &c.) have shown practically undiminished birth and marriage-rates and a steady growth in population.

The intensity of emigration is measured not by the absolute number of emigrants, but by the number of emigrants to the total population. Its effect is shown by comparing the number of emigrants with the excess of births over deaths per 1000 of the population. This is shown in the following table (1905):—

	Excess of births over deaths per 1000 Inhabitants.	Emigrants per 1000 Inhabitants.
Great Britain and Ireland	11·4	6·06
England and Wales	12·0	4·96
Scotland	12·2	8·45
Ireland	6·3	11·42
Germany	13·2	·45
Switzerland	9·5	1·45
Sweden (1903)	10·6	6·89
Norway	12·6	9·11
Denmark	13·5	3·12
Italy	10·6	14·33
Austria-Hungary	12·2	6·29

It will be observed that, with the exception of Ireland and Italy, wherever there is a heavy emigration there is usually a considerable excess of births over deaths, *i.e.* natural increase more than makes up for the loss by emigration. Even taking Great Britain and Ireland together, the loss by emigration per annum has not been very large, as is shown by the following table:—

Annual Emigration per 1000 of the Average Population of Great Britain and Ireland.

1853–1855	8·4	1881–1890	7·1
1856–1860	4·3	1891–1895	5·1
1861–1870	5·2	1896–1900	3·7
1871–1880	5·1	1901–1905	5·5

Even in particular districts where emigration is heavy the loss is made up by births. For instance, in 1891 the emigration from the provinces of West Prussia and Posen was extraordinarily heavy—10·9 and 10·4 per mille respectively—but the excess of births over deaths was 19·6 per mille. Emigration may give temporary relief to congested districts, but it is not in itself a remedy for so-called over-population.

It is difficult to analyse closely the economic effect of emigration, because so much depends upon the character of the emigrants and the condition of the labour market. The following considerations have been urged at different times: Although emigration does not diminish population, yet, as the emigrants are in the most productive period of life (15 to 45), the country of emigration loses adults and replaces them with children. It thereby loses the cost of rearing that number of people to adult age, and is left with a disproportionate number of children and old people. The age distribution of the population of Ireland lends some support to this view. In the same vein it is urged that voluntary emigration takes away the cream of the working-classes. It is the man of energy, of some means, of ambition, who takes the chances of success in the new country, leaving the poor, the indolent, the weak and crippled at home. It is maintained that such emigration institutes a process of selection which is unfavourable to the home country.

On the other side, it is said that the men who are doing well at home are the ones least likely to emigrate, because they have least to gain. Modern means of transportation have made the voyage so cheap that almost any one is able to go. It is therefore the restless, the unsuccessful, or at least those not fitted for the strenuous competition of the older countries, who are tempted to go. Emigration affords a natural outlet for the superfluous labour force of a country. The supply of labour is somewhat reduced, but wages are kept up for those who remain. Those who go find means of bettering their own condition beyond the seas, where they become producers of food and raw material for the home country, and at the same time customers for her manufactured products. Emigration is therefore an economic gain, both directly and indirectly. It is evident from these arguments that no general answer can be given to the question. In some cases it may be an evil; in most, when conducted under normal conditions, it would seem to offer little danger.

The same remark would hold true in regard to the social and political effects of emigration. In some cases, by taking away the strong, self-reliant and energetic, it may result in the deterioration of the home population. In other cases it allows restless spirits who have failed at home to try again elsewhere. Often in cases of political revolution the members of the defeated party have sought refuge elsewhere, as after the revolutionary movements of 1848. In case of conquest the conquered nationality takes to emigration on an extensive scale, as after the absorption of Alsace-Lorraine by Germany in 1871. The movement may be aided either by the state or by private associations. Of such character have been the *state-aided* emigration from Ireland, and the *assisted* emigration of paupers, criminals and other persons in the effort to relieve a congested population, or simply from the desire to get rid of undesirable members of the community. Such efforts fail if the new countries are unwilling to admit these persons. Finally, we have the expulsion of the Jews from Russia as an example of the effort of a community to get rid of an element which has made itself obnoxious to the local sentiment.

Effects of Immigration.—The effects of emigration are negative in character; those of immigration are positive. (*a*) On population: immigration, of course, is a direct addition to the population of new countries, and greatly accelerates the growth by natural increase, especially as the immigrants are in the most productive ages of manhood and womanhood. In the United States, for instance, out of a population of 76,303,387 (in 1900), there were 26,147,407 persons who were either foreign-born or who had one or both parents foreign-born. This does not mean that the population would have been twenty-six millions less if it had not been for immigration; for the rate of natural increase among the native-born might have maintained itself. Nevertheless, immigration has probably stimulated the growth of population. (*b*) Economic effects: The economic gain of immigration to new countries is evident. It adds directly to their available labour force, that is, to the number of adults engaged in the work of producing wealth.

According to the United States census of 1900, out of 29,073,233 (1900) persons engaged in gainful occupations, 5,851,399 or 20·1%, were of foreign birth. If we add to these the native whites of foreign parentage (5,300,924) we have 11,152,323 persons of foreign extraction or 39·4% of the total labour force. The foreign whites alone constituted 10·4% of the total number of persons engaged in agricultural pursuits; 11·4% of those in professional services; 25·7% in domestic and personal services; 19·2% in trade and transportation; and 30·6% of those engaged in manufacturing and mechanical industries. In addition to these, the native whites of foreign parentage constituted, in agriculture, &c., 10·6%; in professional service, 20·6%; in domestic and personal service, 16·4%; in trade and transportation, 25·7% in manufacturing and mechanical, 25·4% of all those engaged in those occupations. The labour force of the United States is thus made up very largely of immigrants and the children of immigrants.

Attempts have sometimes been made to put a money value on the economic gain by immigration. The amount of money brought by the immigrants is not large, and is probably more than offset by the money sent back by immigrants for the support of families and friends at home or to aid them in following. The valuable element is the able-bodied immigrant himself as a factor of production. It is said, for instance, that an adult slave used to be valued at from $800 to $1000, so that every adult immigrant may be looked upon as worth that sum to the country. Or, it has been said that an adult immigrant represents what it would cost to bring up a child from infancy to the age, say, of 15. This has been estimated by Ernst Engel as amounting to $550 for a German child. The most scientific procedure, however, is to calculate the probable earnings of the immigrant during the rest of his lifetime, and deduct therefrom his expenses of living. The remainder represents his net earnings which he will contribute to the well-being of the new country. W. Farr reckoned this to be, in the case of unskilled English emigrants, about £175. Multiplying the total number of adult immigrants by any one of these figures, we get the annual value of immigration. Such attempts to put a precise money value on immigration are futile. They neglect the question of quality and of opportunity. The immigrant is worth what it has cost to bring him up only if he is able-bodied, honest and willing to work. If he is diseased, crippled, dishonest or indolent, he may be a direct loss to the community instead of a gain. So, too, the immigrant is worth his future net earnings to the community only if there is a demand for his labour.

Social and Political Effects of Immigration.—The influx of millions of persons of different nationality, often of a foreign language and generally of the lower classes, would seem to be a danger to the homogeneity of a community. The United States, for instance, has felt some inconvenience from the constant addition of foreigners to its electorate and its population. The foreign-born are more numerously represented among the criminal, defective and dependent classes than their numerical strength would justify. They also tend to segregate more or less, especially in large cities. Nevertheless, the process of assimilation goes on with great rapidity. Intermarriage with the native-born occurs to a considerable extent. The influence of the physical environment leads to the adoption of the same mode of life. The most powerful influences, however, seem to be social. These are common school education and the adoption of one language (English); participation in political life, which is granted to all adult males after five years' residence; and the general influence of social standards embodied in laws, institutions and customs already established. Doubtless immigration in the last fifty years of the 19th century had a modifying effect on American life; but on the whole the power of a modern civilized community working through individual freedom to assimilate elements not differing from it too radically has been displayed to a remarkable degree.

Restriction of Immigration.—New countries have sought to escape certain evils of indiscriminate immigration. These evils were as follows: (*a*) The immigration of criminals, paupers, persons diseased in mind or body, and persons unable to support themselves. By the Acts of 1882 and 1893 such persons were refused admission to the United States, and, when rejected, the steamship companies that brought them were compelled to take them back. The number debarred from 1896 to 1905 is shown in the following table:—

Causes.	1896	1897	1898	1899	1900	1901	1902	1903	1904	1905
Insane	10	6	12	19	32	16	27	23	33	92
Paupers	2010	1277	2261	2599	2974	2798	3944	5812	4798	7898
Diseased	2	1	258	348	393	309	709	1773	1560	2198
Assisted	—	3	79	82	2	50	—	9	38	19
Convicts	—	1	2	8	4	7	9	51	35	39
Prostitutes	—	—	—	—	7	3	3	13	9	24
Contract Labourers	776	328	417	741	833	327	275	1086	1501	1164
All other	1	1	1	1	1	6	7	2	20	445
Total debarred	2799	1617	3030	3798	4246	3516	4974	8769	7994	11,879

No law of international comity is violated by the refusal to receive these unfortunates. They should be taken care of at home. The English legislature in 1905 passed an act to prevent the landing of undesirable aliens, and the number refused admission in 1906 was 493. (*b*) Immigration sometimes increases the competition in the labour market, and thus lowers wages. One case is particularly aggravating, viz. when employers import foreign labourers in order to take the place of their men who are on strike. In 1885 the United States passed what is called the Contract Labor Law, forbidding the landing of any person who is under contract to perform labour in the United States. It is very difficult to discover such cases, but the number rejected is fairly large (see table above). (*c*) The immigration of men of alien race who refuse to assimilate with the natives is said sometimes to be a danger to the country. This at least is the excuse for the entire exclusion of Chinese labourers from the United States since 1882 (provisions made more severe in 1888 and 1892) (see also the article COOLIE).

Internal Migration.—In modern times there is constant movement of population within national lines, from section to section, and especially from rural districts to the cities. No record is kept of this, and we can trace it only through the census statistics of birthplace. In the United States, for instance, it was shown in 1890 that more than 21·5 per cent. of the native-born inhabitants were living in a state other than that in which they were born. Still further, it appears that about one-half of the native-born inhabitants had moved out of the county in which they were born. In 1890 there were 1,233,629 natives of the state of New York living in other states. The movement is principally westwards in direction and along parallels of latitude. For instance, New York has made large contributions to the population of Ohio, Michigan, Illinois, Wisconsin, Iowa and so on. Virginia has contributed largely to the population of West Virginia, Kentucky, Ohio, Indiana, Illinois and Missouri. In Europe there is a similar movement; but it is difficult to make comparisons, because of the differences in the administrative areas. In England in 1891, 71·6% of the population were residing in their native county; in Prussia, 69·7% in the *kreis*; in France, 81·7% in the department; in Austria, 80·2% in the *bezirk*; in Switzerland, 82·1% in the canton where they were born (Weber, *Growth of Cities*, p. 249). The most important phase of internal migration is the movement from the rural districts to the cities. The statistical results are shown in the following table extracted from the admirable work of Weber, just quoted:—

Percentage of Population living in Towns of 10,000 and over at Three Periods.

	About 1800 or 1801.	About 1850 or 1851.	About 1890 or 1891.
England and Wales	21·3	39·5	61·7
Scotland	17·0	32·2	50·0
Australia (7 colonies)	—	—	41·4
Belgium	13·5	20·8	34·8
Netherlands	29·5	29·0	31·3
Prussia (1816)	7·3	10·6	30·0
United States	3·8	12·0	27·6
France	9·5	14·4	25·9
Denmark	10·9	9·6	23·6
Italy	—	—	20·6
Ireland	7·8	10·1	18·0
Norway	3·3	5·3	16·7
Switzerland (1822)	4·3	7·3	16·5
Austria	4·4	5·8	15·8
Hungary	5·4	9·1	16·1
Sweden	3·9	4·7	13·7
Portugal	12·7	2·9	12·7
Russia	3·7	5·3	9·3

Everywhere the city population is increasing faster than the rural. In the United States the rate of increase per decade was as follows:—

Year.	United States.	In Towns of 8000 and over.	Rural Districts.
	%	%	%
1790–1800	35·1	60	34
1800–1810	36·4	69	35
1810–1820	33·0	33	33
1820–1830	33·6	82	31
1830–1840	32·7	68	30
1840–1850	35·9	99	30
1850–1860	35·6	75	30
1860–1870	22·6	59	15
1870–1880	30·1	40	27
1880–1890	24·9	61	15
1890–1900	20·8	37	14

In England and Wales the rural population increased in the aggregate during the first half of the 19th century, but at a gradually diminishing rate; in the second half of the century the population declined with varying regularity, until the decennium 1891–1900, when there was an increase. But notwithstanding this aggregate increase there are many rural districts which still show a steadily declining population. The urban population is increasing, as shown in the following table:—

Decennial Rate of Increase or Decrease.

Year.	Urban.	Rural.
	%	%
1851–1861	+21·9	+1·88
1861–1871	+28·1	−5·86
1871–1881	+25·6	−3·84
1881–1891	+18·5	−2·76
1891–1900	+15·22	+2·94

Somewhat the same phenomenon is seen in France. According to the census of 1891 not less than 55 out of the 87 departments had decreased in population; and out of the 32 that had increased, 7 showed a decrease in their rural parts when the large towns were deducted. In Germany the towns of 10,000 and over show a much more rapid increase than the rural districts; and the same fact is generally true of the other countries of Europe. This more rapid increase of population in cities is due only in part to migration from the country. Until the 19th century deaths generally exceeded births in cities, so that if it had not been for constant immigration the cities would not only not have grown, but would have decreased in population. Cities grow more rapidly now than formerly, because the excess of deaths over births has been turned into an excess of births over deaths. Thereby the cities are becoming less dependent upon immigration for increase of population than formerly, but the migration still goes on. The causes of migration from country to city are mainly economic. In early stages of culture men are scattered over the country, or at most gathered together in hamlets and villages. Each of these is self-sufficing, having its own artisans and handicraftsmen, and producing what it needs. With the beginning of exchange commercial centres spring up, situated on navigable streams and especially at points where land and water journeys are broken. With the growth of manufactures, industrial centres spring up where the division of labour can be fully provided for. In modern times two factors have accelerated this process, viz.: (1) the building of railways, which have developed commerce to a very great degree and favoured the large towns at the expense of the small; and (2) the invention of machinery, which has greatly increased the possibility of division of labour and manufactures on a large scale. The old handicraftsman has been superseded by machine labour and the village artisan by the factory hand. At the same time improvements in agriculture and the opening up of new countries have enabled the modern community to gain its food and raw material with a less expenditure of labour force, and the surplus agricultural population has gone to the city. The attractive influences upon individuals have been higher wages, greater scope for the ambitious, and the social advantages of city life.

The general laws of internal migration may be summarized (according to Ravenstein) as follows:—

1. The great body of migrants proceed only a short distance.

2. The process of absorption goes on as follows: The inhabitants of the country immediately surrounding a town of rapid growth flock into it; the gaps thus left in the rural population are filled up by migrants from more remote districts, until the attractive force of one of the rapidly-growing cities makes its influence felt, step by step, to the most remote corner of the land. Migrants enumerated in a certain centre of absorption will consequently grow less with the distance, proportionately to the native population which furnishes them.

3. The process of dispersion is the inverse of that of absorption, and exhibits similar features.

4. Each main current of migration produces a compensating countercurrent.

5. Migrants proceeding long distances generally go by preference to one of the great cities of commerce or industry.

6. The natives of towns are less migratory than those of the rural parts of the country.

7. Females are more migratory than males.

AUTHORITIES.—The statistics of migration are to be found in the official returns of different countries, especially the statistical tables relating to emigration and immigration published by the British Board of Trade, and the Reports (annual) of the Commissioner-General of Immigration of the United States. For general discussion see Philippovich, *Auswanderung und Auswanderungspolitik* (Leipzig, 1892). An exhaustive bibliography will be found in an article by same author, "Auswanderung," in *Handwörterbuch der Staatswissenschaften*; R. Mayo-Smith, *Emigration and Immigration*, with bibliography (New York, 1890). For internal migration see A. F. Weber, *Growth of Cities* (New York, 1899). See also Ravenstein, "The Laws of Migration," in *Journal of Royal Statistical Society* (1885 and 1889). Professor Flinders Petrie, in his Huxley Lecture for 1906 on *Migrations* (reprinted by the Anthropological Institute), deals with the mutations and movements of races from an anthropological standpoint with profound knowledge and originality.

(R. M.-S.; T. A. I.)

MIGRATION, in Zoology. In zoology considerable importance attaches to the problems of migration, by which is meant the wandering of living creatures into another, usually distant, locality in order to breed there; this implies a return, and the double phenomenon is annual. All other changes of the abode are either sporadic, epidemic, or fluctuating within lesser limits. Further, migration should not be confounded with "spreading," which proceeds steadily, and in epicycles, with a totally different result. It need not be emphasized that hard and fast lines between these phenomena do not exist; they are often a question of degree. For instance, when the common toad, which is a strictly terrestrial creature, wanders every spring to a frequently distant pool in order to spawn there, this is a true migration. The same applies, strictly speaking, to those insects which hibernate in the ground, at the root of the tree on which they feed and breed. The grey plover breeds in the arctic circle and winters in equatorial countries. To complicate matters further, it is not necessary that the migration be undertaken periodically, more than once, by the same individual. For instance, the common eel ascends the rivers as an elver in its youth; years after it returns to the sea, there to breed and to die, whilst other fishes come and go, year after year. Further, some of the larger birds, for instance swans and cranes, are still immature in their second year, and yet they migrate like their older relations. It seems permissible to use this fact as an indication that the breeding as such is not the prime reason of their wanderings. The fundamental impelling agent must have been the want of food, and what we usually understand by migration cannot suddenly have sprung into existence to its full extent, but is more likely the cumulative effect of the doings of countless generations. The faculty of shifting the abode was of course always there, the necessity of moving further on was also present, and those which went in the wrong direction came to grief, while the others flourished and returned with their progeny. They did not at first cover enormous distances, but just enough to find unoccupied ground. The annual repetiton became an established habit, at last an ineradicable instinct. There can be but little doubt that the prime impulse was want of food. The new growing grass on the prairie or on the veldt attracts every year those creatures which live upon pasture. The inter-tropical belt of the world is so crowded with creatures that there is the keenest competition, whilst in the temperate and cold regions is a long winter quiescence unfit for the support of many creatures, whereas in the summer these same regions are covered with new vegetation, with its concomitant abundance of insects and other invertebrates. The tables are decked again, and these opportunities are not wasted.

The process of migration, in its most striking cases, is now very complicated. Many a bird goes actually to the arctic regions for the shortest of summers, but spends most of the year within the tropics. On the other hand there are many species which do not go so far north, but stop to breed in the intermediate regions. We must not take the extremes when trying to unravel the development of the problem. The periodical migrations of mammals, with their more limited extent and greater leisure, are less perplexing.

It has been argued with some show of reason that the real home of a bird is that country in which it was born, in other words where the species breeds, but this is not in every case a valid conclusion. It applies to most creatures, but it can well bear exceptions if we leave sentiment aside. When it comes to a question of domicile, the ten weeks' sojourn of the swift, *Cypselus*, in England are more than weighted down by the nine months or more which these birds spend in southern countries, although we do not know whether they are resident there or roam about. The breeding time is the busiest period of a bird's life; then the numbers of each species are suddenly multiplied, and so is the stress of providing food, and the particular food which is best for the young may not be available in every country. The idea that the arctic circle is the original home of the numerous kinds of birds which breed in it, whence they are now periodically driven away by stress, has been coupled with the glacial epoch, that supposed solution of so many difficulties. We have only to assume that the old, permanent home of these migrants was in the arctic region, that the progressing glaciation drove them away, of course towards the equator, and that, when times improved again, the birds returned to their old home. This sounds very plausible, but it involves huge assumptions. The birds, not the individuals, but the species, are supposed to have inherited such a loving reminiscence of their old home, that after thousands of years—with most of the small birds meaning as many generations—they returned at the first opportunity. It implies that their long continued sojourn in foreign lands, where—under this assumption—thousands of generations must have been bred and have spent all their lives, was not sufficient to naturalize them, so to speak, in other words to supplant the instinctive love of the primary ancient home. That the last glacial epoch has driven the limit of many kinds of animals and plants farther south is as certain as that many have recovered the lost ground after the reversion of the glaciation, but it must have been a very slow and steady process of spreading. It may, and probably does, account for the present annual visitations of arctic lands, as a phenomenon which has been evolved *de novo*, which would have come to pass even if no birds had existed in pre-glacial times.

How do birds manage to find their way, thousands and thousands of miles across land and water? This question has been extolled as a mystery of mysteries. It has been stated that the old birds show the way to the young, a speculation which does not apply to those many cases in which old and young notoriously travel at different times. It has been assumed that they travel by sight, taking advantage of certain landmarks; another untenable idea, since—experience having to be excluded in a flock of birds which made the journey for the first time—it implies that the young must have inherited the reminiscence of those landmarks! Others have likened the bird to a kind of compass, because in eastern Siberia E. von Middendorff found some migration routes to coincide with the direction of the magnetic pole. The whole question reduces itself to a sense of direction, a faculty which is possessed by nearly all animals; in some it is present to an astonishing extent; but the manifestations of this sense vary only in degree. The cat which escapes out of the bag finds its way back, directly or after many adventures. The bee, after having loaded itself with pollen, returns by the proverbial line to the hive which may be a mile away, but, move the small entrance hole in the meantime an inch to the right or left, and the bee will knock its head against the hive and blunder about; move the hive a few yards and bee after bee returning will be puzzled to find its hive again. They, maybe with the help of landmarks, have accustomed themselves to steer a course. Such instances need not be multiplied. The principle is the same whether the journey be one of a few yards or of many miles. Given the sense of direction, it is no more difficult to steer a course due north than it is to lay one south-east by east, provided always the impetus to be on the move. There is no mystery, except that we, the most intellectual of mankind, should so well nigh have lost this sense, and even this fact is simply an instance of the loss of a faculty through long-continued disuse.

Birds.—(The following account is to a great extent based upon A. Newton's article "Birds" in *Ency. Brit.*, 9th ed.)

In almost all countries there are some species which arrive in spring, remain to breed, and depart in autumn; others which arrive in autumn, stop for the winter and depart in spring; and others again—and these are strictly the "birds of passage"—which show themselves but twice a year, passing through the country without staying long in it, and their transient visits take place about spring and autumn. These three apparently different categories of migrants are all acted upon by the same impulse in spite of the at first sight dissimilar nature of their movements. The species which resort to Britain and to other temperate countries in winter are simply those which have their breeding quarters much nearer the poles, and in returning to them on the approach of spring are but doing exactly as do those species which, having their winter abode nearer the equator, come to us with the spring.

The birds-of-passage proper, like our winter visitants, have their breeding quarters nearer the pole, but like our summer visitants, they seek their winter abode nearer the equator, and thus perform a somewhat larger migration. As H. Seebohm puts it (*Geograph. Distrib. of the family Charadriidae*, London):—

"They all represent birds which breed in the north and winter in the south. Every migratory bird wintering in England goes north to breed, and every migratory bird breeding in England goes south to winter. It is a rule without exception in the northern hemisphere that each bird breeds in the extreme north point of its migrations. To make the rule apply to the southern hemisphere as well it must be modified as follows: each bird breeds in the coldest climate which it visits on its migrations. . . . It is a remarkable fact that whilst there are many birds breeding in the northern hemisphere and wintering in the southern, it is not known that any land-bird breeds in the southern and habitually winters in the northern! This is probably owing to the difference in the distribution of the land, there being no antarctic breeding grounds. . . . Birds breeding in the tropics are always resident, except when they breed on mountains, where the climate causes them to descend into the valleys for the winter."

In many countries we find that while there are some species, such as in England the swallow or the fieldfare, of which every individual disappears at one period of the year or another, there are other species, such as the pied-wagtail or the woodcock, of which only the majority of individuals vanish—a few being always present—and these species form the so-called "partial migrants." In England the song-thrushes receive in the autumn a considerable accession in numbers from the birds which arrive from the north, though the migration is by no means so well marked as it is on the continent, where the arrival of the strangers sets all the fowlers at work. In most localities in Britain the newcomers depart after a short sojourn, and are accompanied by so many of the home-bred birds that in some parts of the island it may be safely declared that not a single song-thrush can be found from the end of November to the end of January, while in others examples can always be seen. Much the same may be said of the redbreast. Undeniably resident as a species, attentive scrutiny will reveal the fact that its numbers are subject to very considerable variation, according to the season of the year. At no time do our redbreasts collect in bands, but towards the end of summer they may be seen in the south of England successively passing onward, the travellers being mostly—if not wholly—young birds of the year; and so the great majority disappear, departing it may be safely presumed for more southern countries, since a few weeks later the markets of most towns, first in France and then in Italy, are well supplied with this species. But the migratory influence affects, though in a less degree, many if not most of the redbreasts that remain with us. Every bird of the northern hemisphere is to a greater or less degree migratory in some part or other of its range.

Want of food, and perhaps of the special, proper kind during the breeding season, seems to be the most obvious cause of migration, and none can wonder that those animals which possess the power of removing themselves from a place of scarcity should avail themselves of it, while it is unquestionable that birds possess this faculty in the greatest degree. Even among those species which we commonly speak of as sedentary it is only the adults which maintain their ground throughout the year. It has long been known that birds-of-prey customarily drive away their offspring from their own haunts so soon as the young are able to shift for themselves. The reason generally, and no doubt truly, given for this behaviour, which at first sight appears so unnatural, is the impossibility of both parents and progeny getting a livelihood in the same vicinity. The practice, however, is not limited to the birds-of-prey alone, but is much more universal. We find it to obtain with the redbreast, and if we watch our feathered neighbours closely we shall perceive that most of them indulge in it. The period of expulsion, it is true, is in some birds deferred from the end of summer or the autumn, in which it is usually performed, until the following spring, when indeed from the maturity of the young it must be regarded as much in the light of a voluntary secession on their part as in that of an act of parental compulsion, but the effect is ultimately the same.

The mode in which the want of sustenance produces migration may best be illustrated by confining ourselves to the unquestionably migrant birds of our own northern hemisphere. As food grows scarce towards the end of summer in the most northern limits of the range of a species, the individuals affected thereby seek it elsewhere. Thus doing, they press upon the haunt of other individuals: these in like manner upon that of yet others, and so on, until the movement which began in the far north is communicated to the individuals occupying the extreme southern range of the species at that season; though, but for such an intrusion, these last might be content to stay some time longer in the enjoyment of their existing quarters.

This seems satisfactorily to explain the southward movement of all migrating birds in the northern hemisphere; but when we consider the return movement which takes place some six months later, doubt may be entertained whether scarcity of food can be assigned as its sole or sufficient cause, and perhaps it would be safest not to come to any decision on this point. On one side it may be urged that the more equatorial regions which in winter are crowded with emigrants from the north, though well fitted for the resort of so great a population at that season are deficient in certain necessaries for the nursery. Nor does it seem too violent an assumption to suppose that even if such necessaries are not absolutely wanting, yet that the regions in question would not supply sufficient food for both parents and offspring—the latter being at the lowest computation twice as numerous as the former—unless the numbers of both were diminished by the casualties of travel.[1] But on the other hand we must remember what has above been advanced in regard to the pertinacity with which birds return to their accustomed breeding-places, and the force of this passionate fondness for the old home cannot but be taken into account, even if we do not allow that in it lies the whole stimulus to undertake the perilous voyage.

A. R. Wallace in some remarks on the subject (*Nature*, x. 459) ingeniously suggests the manner in which the habit of migration has come to be adopted[2]:—

"It appears to me probable that here, as in so many other cases, 'survival of the fittest' will be found to have had a powerful influence. Let us suppose that in any species of migratory bird, breeding can as a rule be only safely accomplished in a given area; and further, that during a great part of the rest of the year sufficient food cannot be obtained in that area. It will follow that those birds which do not leave the breeding area at the proper season will suffer, and ultimately become extinct; which will also be the fate of those which do not leave the feeding area at the proper time. Now, if we suppose that the two areas were (for some remote ancestor of the existing species) coincident, but by geological and climatic changes gradually diverged from each other, we can easily understand how the habit of incipient and partial migration at the proper seasons would at last become hereditary, and so fixed as to be what we term an instinct. It will probably be found that every gradation still exists in various parts of the world, from a complete coincidence to a complete separation of the breeding and the subsistence areas; and when the natural history of a sufficient number of species is thoroughly worked out we may find every link between species which never leave a restricted area in which they breed and live the whole year round, to those other cases in which the two areas are absolutely separated."

A few more particulars respecting migration are all that can here be given, and it is doubtful whether much can be built upon them. It has been ascertained by repeated observation that in the spring-movement of most species of the northern hemisphere the cock-birds are always in the van of the advancing army, and that they appear some days, or perhaps weeks, before the hens. It is not difficult to imagine that, in the course of a journey prolonged throughout some 50° or 60° of latitude, the stronger individuals should outstrip the weaker by a very perceptible distance, and it can hardly be doubted that in most species the males are stronger, as they are bigger than the females. Some observers assert that the same thing takes place in the return journey in autumn—Seebohm, for instance, says that, from Europe, first go the young, then the males, having finished their moult of autumn, and lastly the females—but on this point others are not so sure, which is not surprising when we consider that the majority of observations have been made towards what is the northern limit of the range of the *Passeres*, to which the remark is especially applicable—in the British islands, France, North Germany and the Russian empire—for it is plain that at the beginning of the journey any inequality in the speed of travelling will not have become so very manifest. There is also another matter to be noticed. It has been suspected that where there is any difference in the size of birds of the same species, particularly in the dimensions of their wings, the individuals that perform the most extensive journeys would be naturally those with the longest and broadest *remiges*, and in support of this view it certainly appears that in some of the smaller migrants—such as the wheatear (*Saxicola oenanthe*) and willow-wren (*Phylloscopus trochilus*)—the examples which reach the extreme north of Europe and there pass the summer possess greater mechanical powers of flight than those of the same species which stop short on the shores of the Mediterranean. It may perhaps be also inferred, though precise evidence is wanting, that these same individuals push further to the southward in winter than do those which are less favoured in this respect. It is pretty nearly certain that such is the case with some species, and it may well be so with individuals. H. B. Tristram has remarked (*Ibis*, 1865, p. 77) that, in many genera of birds, "those species which have the most extended northerly have also the most extended southerly range; and that those which resort to the highest latitudes for nidification also pass further than others to the southward in winter," fortifying his opinion by examples adduced from the genera *Turdus*, *Fringilla*, *Cypselus* and *Turtur*.

---

[1] If the relative proportion of land to water in the southern hemisphere were at all such as it is in the northern, we should no doubt find the birds of southern continents beginning to press upon the tropical and equatorial regions of the globe at the season when they were thronged with the emigrants from the north, and in such a case it would be only reasonable that the latter should be acted upon by the force of the former, according to the explanation given of the southward movement of northern migrants. But, though we know almost nothing of the migration of birds of the other hemisphere, yet, when we regard the comparative deficiency of land in southern latitudes all round the world, it is obvious that the feathered population of such as nowadays exists can exert but little influence, and its effects may be practically disregarded.

[2] In principle F. W. Hutton had already foreshadowed the same theory (*Trans. New Zeal. Inst.*, 1872, p. 235).

For many years past a large number of persons in different countries have occupied and amused themselves by carefully registering the dates on which various migratory birds first make their appearance, and there is now an abundance of records so compiled. Still it does not seem that they have been able to determine what connexion, if any, exists between the arrival of birds and the weather; in most cases no corresponding observations have been made about the weather in the places whence the travellers are supposed to have come. As a rule it would seem as though birds were not dependent on the weather to any great degree. Occasionally the return of the swallow or the nightingale may be somewhat delayed, but most sea-fowls may be trusted, it is said, as the almanac itself. Foul weather or fair, heat or cold, the puffins (*Fratercula arctica*) repair to some of their stations punctually on a given day as if their movements were regulated by clockwork. Whether they have come from far or from near we know not, but other birds certainly come from a great distance, and yet make their appearance with scarcely less exactness. Nor is the regularity with which certain species disappear much inferior; every observer knows how abundant the swift (*Cypselus apus*) is up to the time of its leaving its summer-home—in most parts of England, the first days of August—and how rarely it is seen after that time is past.

It must be allowed, however, that, with few exceptions, the mass of statistics above spoken of has never been worked up and digested so as to allow proper inferences to be made from it, and therefore it would be premature to say that little would come of it, but the result of those exceptions is not very encouraging. E. von Middendorff carefully collated the records of the arrival of migratory birds throughout the Russian Empire, but the insight into the question afforded by his published labours is not very great. His chief object has been to trace what he has termed the *isepipteses* (ἴσος = *aequalis*, ἐπίπτησις = *advolatus*) or the lines of simultaneous arrival, and in the case of seven species these are laid down on the maps which accompany his treatise. The lines are found by taking the average date of arrival of each species at each place in the Russian dominions where observations have been regularly made, and connecting those places where the dates are the same for each species by lines on the map. The curves thus drawn indicate the inequality of progress made by the species in different longitudes, and assuming that the advance is directly across the isepiptesial lines, or rather the belts defined by each pair of them, the whole course of the migration is thus most accurately made known. In the case of his seven sample species the maps show their progressive advance at intervals of a few days, and the issue of the whole investigation, according to him, proves that in the middle of Siberia the general direction of the usual migrants is almost due north, in the east of Siberia from south-east to north-west, and in European Russia from south-west to north-east. Thus nearly all the migrants of the Russian empire tend to converge upon the most northern part of the continent, the Taimyr peninsula, but it is almost needless to say that few of them reach anything like so far, since the country in those high latitudes is utterly unfit to support the majority. With the exception of some details this treatise fails to show more. The routes followed by migratory birds have been the subject of a very exhaustive memoir by J. A. Palmén, but it would be beyond our limits to do more than mention his results concisely. He enters very fully into this part of the inquiry and lays down with much apparent probability the chief roads taken by the most migratory birds of the palaearctic region in their return autumnal journey, further asserting that in the spaces between these lines of flight such birds do not usually occur. Broadly speaking, the birds of Europe, Russia and Western Siberia go for the winter to Africa, those of middle Siberia to Mongolia, and those of Siberia east of the Lena go towards Japan.

But lay down the paths of migratory birds, observe their comings and goings, or strive to account for the impulse which urges them forward as we will, there still remains for consideration the most marvellous thing of all—how do the birds find their way so unerringly from such immense distances? This seems to be by far the most inexplicable part of the matter. Year after year the migratory wagtail will build her nest in the accustomed spot, and year after year the migratory cuckoo will deposit her eggs in that nest, and yet in each interval of time the former may have passed some months on the shores of the Mediterranean, and the latter, absent for a still longer period, may have wandered into the heart of Africa. That particular form of bluethroat which yearly repairs to breed upon the mosses of the subalpine and northern parts of Scandinavia (*Cyanecula suecica*) is hardly ever seen in Europe south of the Baltic. Throughout Germany it may be said to be quite unknown, being replaced by a conspicuously different form (*C. leucocyana*), and as it is a bird in which the collectors of that country, a numerous and well-instructed body, have long taken great interest, we are in a position to declare that it is not known to stop in its transit from its winter haunts, which we know to be Egypt and the valley of the Upper Nile, to its breeding-quarters. Other instances, though none so crucial as this, could be cited from among European birds were there room here for them. In New Zealand there are two cuckoos which are annual visitors: one, a species of *Chrysococcyx*, is supposed to come from Australia, the other, *Eudynamis taitensis* is widely spread throughout Polynesia, yet both these birds yearly make two voyages over the enormous waste of waters that surrounds the country to which they resort to breed. But space would utterly fail us were we to attempt to recount all the examples of these wonderful flights. Yet it seems impossible that the sense of sight should be the faculty whereby they are so guided to their destination, any more than in the case of those which travel in the dark. J. A. Palmén asserted (*op. cit.* p. 195) that migrants are led by the older and stronger individuals among them, and, observing that most of those which stray from their right course are yearlings that have never before taken the journey, he ascribed the due performance of the flight to "experience." There are many birds which cannot be said to migrate in company. While swallows, to take a sufficiently evident example, conspicuously congregate in vast flocks and so leave our shores in large companies, the majority of our summer-visitors slip away almost unobserved, each apparently without concert with others. Experience here can only signify the result of knowledge acquired on former occasions and obtained by sight. Now it was stated by C. J. Temminck (*Manuel d'ornithologie*, III. Introd., 1820) many years ago, and so far as would appear the statement has not been invalidated, that among migrants the young and the old always journey apart and most generally by different routes. The former can have no "experience," and yet the greater number of them safely arrive at the haven where they would be. The sense of sight, essential to a knowledge of landmarks, is utterly insufficient to account for the success that attends birds which travel by night, or in a single flight span oceans or continents. Yet without it the idea of "experience" cannot be substantiated. We may admit that inherited but unconscious experience, which is really all that can be meant by instinct, is a factor in the whole matter—certainly, as Wallace seems to have proved, in originating the migratory impulse, but yet every aspect of the question is fraught with difficulty.

Less than nothing is known about the speed at which birds fly during their long stretches of migration. Gaetke, in his otherwise very interesting book, has startled ornithologists by various statements, but his calculations were based upon such crude observations that the results are ridiculous. For instance, he proved to his satisfaction that the grey or hooded crow, *Corvus cornix*, which notoriously is not a fast bird, flies from Heligoland to the coast of Lincolnshire in England at the rate of one hundred and twenty miles an hour. To the little bluethroat he assigned a velocity of two hundred and forty miles an hour, a statement as silly as that made by some fanciful observer in Portugal who convinced himself that "Turtle-doves leaving Kent or Surrey at dawn might easily be the very birds that a few hours later were skimming over the Portuguese pine forests on their way to Central Africa." Fifty miles an hour would be a high average speed for most migratory birds, and there are no reliable data to tell how long such birds can continue their flight without interruption. All we seem to know is that not a few kinds manage, in various parts of the world, to cross enormous distances without the chance of a break. It was Gaetke's notion that migration was for the most part carried on at such a height in the air as to be beyond our ken, and that what comes to our perception consists chiefly of the abortive or unsuccessful attempts, when birds are checked in their course, and being unable to proceed present themselves to our sight and hearing. Now for obvious reasons birds could not well fly at very great heights in very thin air, as experiments with pigeons released from balloons have shown, and the condor soaring far above the tops of the Andes is a myth. The few trustworthy instances in which birds have been observed through a telescope passing across the face of the moon have naturally yielded but vague calculations as to distance and height. W. E. D. Scott (*Bull. Nuttall Orn. Club*, vi. 97–100), computed heights varying from 1 to 2 m. F. M. Chapman's observations (*Auk*, 1888, pp. 37–39) resulted in a height of from 1500 to 15,000 ft.; average, say, 1 m. If the sky is clouded and the birds fly above the clouds the migration proceeds beyond our ken, and if for some reason or other they are below the clouds the phenomenon becomes to us very noticeable. It is well known "that on clear and bright nights birds are rarely heard passing overhead, while on nights that are overcast, misty and dark, especially if slight rain be falling, flocks may often be heard almost continuously." It is in such weather, continues Newton, that birds while migrating are most vociferous, doubtless with the result that thereby the company of fellow-travellers is kept together.

There yet remain a few words to be said on what may be termed Exceptional Migration, that is when from some cause or other the ordinary practice is broken through. The erratic movements of the various species of crossbill (*Loxia*) and some allied forms afford perhaps the best-known examples. In England no one can say in what part of the country or at what season of the year he may not fall in with a company of the common crossbill (*L. curvirostra*), and the like may be said of many other lands. The food of these birds consists mainly of the seeds of conifers, and as its supply in any one locality is intermittent or precarious, we may not unreasonably guess that they shift from place to place in its quest, and may thus find an easy way of accounting for their uncertain appearance. The great band of nutcrackers (*Nucifraga caryocatactes*) which in the autumn of 1844 pervaded western and central Europe (*Bull. Acad. Bruxelles*, xi. 298), may also have been actuated by the same motive, but we can hardly explain the roaming of all other birds so plausibly. The inroads of the waxwing (*Ampelis garrulus*) have been the subject of interest for more than 300 years, and by persons prone to superstitious auguries were regarded as the forerunners of dire calamity. Sometimes years have passed without the bird being seen in central, western or southern Europe, and then perhaps for two or three seasons in succession vast flocks have suddenly appeared. Later observation has shown that this species is as inconstant in the choice of its summer as of its winter-quarters. One of the most extraordinary events known to ornithologists is the irruption into Europe in 1863 of Pallas's sand-grouse (*Syrrhaptes paradoxus*). Of this bird, hitherto known only as an inhabitant of the Tatar steppes, a single specimen was obtained at Sarepta on the Volga in the winter of 1848. In May 1859 a pair is said to have been killed in the government of Vilna, on the western borders of the Russian empire, and a few weeks later five examples were procured, and a few others seen, in western Europe—one in Jutland, one in Holland, two in England and one in Wales. In 1860 another was obtained at Sarepta; but in May and June 1863 a horde computed to consist of at least 700 individuals overran Europe—reaching Sweden, Norway, the Faeroes and Ireland in the northwest, and in the south extending to Sicily and almost to the frontiers of Spain. On the sandhills of Jutland and Holland some of these birds bred, but they were all killed off. A much greater visitation took place in 1888, which met with the same fate. The number of birds was quite incalculable, the wave extending from Norway to southern Spain.

In comparison with the periodic annual migrations of so very many birds, those of other creatures are scarce and insignificant, excepting fishes.

Mammals.—Few trustworthy observations have been recorded. The most regular and least limited migrations seem to be those of the eared seals. The walrus also goes each year to the north in the summer, further south in the winter. *Delphinapterus leucas*, one of the Cetacea, ascends the Amoor regularly on the breaking of the ice, a distance of 400 m. up the stream, Some bats are supposed to migrate. The American bison used to roam north and south, according to the season, in search of pasture; and similar periodic wanderings have often been recorded of various kinds of game on the South African veldt. They are all obviously a mere matter of commissariat and have little to do with the breeding, except in the case of seals.

In one way the lemming's "migrations" are instructive. They are quite sporadic. When, owing to combination of some favourable circumstances they suddenly increase, enormous numbers forsake the highlands for the lowlands of Norway; not in a methodical way, but quite lawlessly; that means to say they radiate from their centres of dispersal. At any given spot, however, they seem to keep to the same direction, and no obstacles seem to divert their course. Those which arrive at the much indented coast are known even to rush into the sea, where of course they get drowned. There is no sense in this. The overcrowded condition of their home impels them to leave, and this impulse continues blindly. They do not attempt to settle anywhere between their home and the sea. A year or two after the irruption not a lemming is there to be found, and where during their stampede they come across suitable districts, they find these already occupied by resident lemmings.

Such and similar irruptions have no doubt taken place often during the world's history; and yet such sporadic stampedes into a foreign country hardly ever lead to its regular settlement, especially when such a country possesses already a kindred fauna of its own.

Fishes.—Many fishes make periodic migrations for breeding purposes, which by their numbers and the distances travelled much resemble those of birds, but very little is known about these fishes. Take the incredible masses of herrings and their kindred; the collecting of the cod and its allies on their breeding-ground. According to D. S. Jordan (*A Guide to the Study of Fishes*, New York, 1905) some kinds are known mainly in the waters they make their breeding-homes, as in Cuba, southern California, Hawaii or Japan, the individuals being scattered at other times through the wide seas. The tunny, which has a world-wide distribution, arrives off the south coast of Portugal in the month of May; enormous numbers pass through the Straits of Gibraltar and support great fishing industries in the Mediterranean. In the month of August they return to the ocean (*A pesca do Atum no Algarve em 1898*, por D. Carlos de Braganza, Lisboa, 1899; with many maps).

Many fresh-water fishes, as trout and suckers (quoting Jordan) forsake the large streams in the spring, ascending the small brooks where their young can be reared in greater safety. Still others, known as *anadromous* fishes, feed and mature in the sea, but ascend the rivers as the impulse of reproduction grows strong. Among such fishes are the salmon, shad, alewife, sturgeon and striped bass in American waters; *Clupea alosa*, the Allis shad, and *C. finta*, the Twait shad, *Alepocephalus rostratus*, the "*maifisch*" of the Rhine, in Europe. "The most remarkable case of the anadromous instinct is found in the king-salmon or quinnat (*Onchorhynchus tschawytscha*), of the Pacific coast. This great fish spawns in November, at the age of four years and an average weight of twenty-two pounds. In the Columbia river it begins running with the spring freshets in March and April. It spends the whole summer, without feeding, in the ascent of the river. By autumn the individuals have reached the mountain streams of Idaho, greatly changed in appearance, discoloured, worn and distorted. On reaching the spawning-beds, which may be 1000 m. from the sea in the Columbia, over 2000 m. in the Yukon, the female deposits her eggs in the gravel of some shallow brook. The male covers them and scrapes the gravel over them. Then both male and female drift, tail foremost, helplessly down the stream; none, so far as certainly is known, ever survive the reproduction act. The same habits are found in the five other species of salmon in the Pacific. The salmon of the Atlantic has a similar habit, but the distance travelled is everywhere much less, and most of the hook-jawed males drop down to the sea and recover, to repeat the act of reproduction."

Few fishes are *katadromous*, i.e. their usual habitat is in rivers and lakes, but they descend into the sea for breeding purposes. The common eel is the classical example.

Insects.—D. Sharp makes the following remarks (*Cambridge Nat. Hist.* vi.): "Odonata are among the few kinds of insects that are known to form swarms and migrate. Swarms of this kind have been frequently observed in Europe and in North America; they usually consist of a species of the genus *Libellula*, but species of various other genera also swarm, and sometimes a swarm may consist of more than one species.

"Locust swarms do not visit the districts that are subject to their invasions every year, but as a rule only after intervals of a considerable number of years. . . . The irregularity seems to depend upon three facts, viz. that the increase of locusts is kept in check by parasitic insects; that the eggs may remain more than one year in the ground and yet hatch out when a favourable season occurs, and that the migratory instinct is only effective when great numbers of superfluous individuals are produced. . . . It is well established that locusts of the migratory species exist in countries without giving rise to swarms or causing any serious injuries. . . . When migration of locusts does occur it is attended by remarkable manifestations of instinct. Although several generations may elapse without a migration, it is believed that the locusts when they migrate do so in the direction taken by predecessors. They are said to take trial flights to ascertain the direction of a favourable wind, and that they alight and wait for a change. The most obscure point is their disappearance from a spot they have invaded. A swarm will alight on a locality, deposit there a number of eggs, and then move on. But after a lapse of a season or two there will be few or none of the species present in the spot invaded. In other cases they again migrate after growth to the land of their ancestors. It has been ascertained by the United States Entomological Commission that such return swarms do occur."

See J. A. Palmén, *Om Foglarnes flyttningsvägar* (Helsingfors, 1874). The same in German: *Über die Zugstrassen der Vögel* (Leipzig, 1896). In this and the work of von Middendorff, already cited, reference is made to almost every important publication on the subject of migration, which renders a notice of its very extensive literature needless here, and a pretty full bibliographical list is given in Giebel's *Thesaurus ornithologiae* (i. 146–155). Yet mention may be made of Schlegel's *Over het trekken der Vogels* (Harlem, 1828); Hodgson's "On the Migration of the *Natatores* and *Grallatores* as observed at Kathmandu" in *Asiatic Researches* (xviii. 122–128), and Marcel de Serres's *Des Causes des migrations des animaux et particulièrement des oiseaux et des poissons* (Harlem, 1842). This last, though one of the largest publications on the subject, is one of the least satisfactory. S. F. Baird's excellent treatise "On the Distribution and Migrations of North American Birds," *Am. Journ. Sc. and Arts* (2nd ser. 1866), pp. 78–90, 187–192, 337–347; reprinted *Ibis* 1867, pp. 257–293. N. A. Severzoff, "Études sur le passage des oiseaux dans l'Asie centrale," *Bull. Soc. Nat.* (Moscow, 1880), pp. 234–287; Menzbier, "Die Zugstrassen der Vögel im europäischen Russland," *op. cit.* (1886), pp. 291–369; Palmén, *Referat über den Stand der Kenntniss des Vogelzuges*, Intern. Ornith. Congr., Budapest, 1891; W. W. Cooke and C. H. Merriam, *Report on Bird Migration in the Mississippi Valley*, U.S. Dep. Agric.-Economic Ornithol., publ. 2 (Washington, 1888); Gaetke, *Die Vogelwarte Helgoland* (Braunschweig, 1891). In English: *Heligoland as an Ornithological Observatory* (Edinburgh, 1895); A. Newton, article "Migration," *Dict. Birds* (1893). (H. F. G.)

MIGUEL, MARIA EVARIST (1802–1866), usually known as Dom Miguel, whose name is chiefly associated with his pretensions to the throne of Portugal, was the third son of King John VI. of Portugal, and of Carlota Joaquina, one of the Spanish Bourbons; he was born at Lisbon on the 26th of October 1802. In 1807 he accompanied his parents in their flight to Brazil, where he grew up an uneducated and fanatical debauchee; in 1821, on his return to Europe, it is said that he had not yet learned to read. In 1822 his father swore fidelity to the new Portuguese constitution which had been proclaimed in his absence; and this led Carlota Joaquina, who was an absolutist of the extremest Bourbon type, and hated her husband, to seek his dethronement in favour of Miguel her favourite son. The insurrections which ensued (see Portugal) resulted in her imprisonment and the exile of Miguel (1824), who spent a short time in Paris and afterwards lived in Vienna, where he came under the teaching of Metternich. On the sudden death of John VI. in May 1826, Pedro of Brazil, his eldest son, renounced the crown in favour of his daughter Maria da Gloria, on the understanding that she should become the wife of Miguel. The last named accordingly swore allegiance to Pedro, to Maria, and to the constitution which Pedro had introduced, and on this footing was appointed regent in July 1827. He arrived in Lisbon in February 1828, and, regardless of his promises, dissolved the new Cortes in March; having called together the old Cortes, with the support of the reactionary party of which his mother was the ruling spirit, he got himself proclaimed sole legitimate king of Portugal in July. His private life was characterized by the wildest excesses, and he used his power to oppose all forms of liberalism.

The public opinion of Europe became more and more actively hostile to his reign, and after the occupation of Oporto by Dom Pedro in 1832, the destruction of Miguel's fleet by Captain (afterwards Sir Charles) Napier off Cape St Vincent in 1833, and the victory of Saldanha at Santarem in 1834, Queen Christina of Spain recognized the legitimate sovereignty of Maria, and in this was followed by France and England. Dom Miguel capitulated at Evora on the 29th of May 1834, renouncing all pretensions to the Portuguese throne. He lived for some time at Rome, where he enjoyed papal recognition, but afterwards retired to Bronnbach, in Baden, where he died on the 14th of November 1866.

MIHRAB, a term in Mahommedan architecture given to the niche which in a mosque indicates the direction of Mecca, towards which the Moslems turn when praying.

MIKADO (Japanese for "exalted gate"), the poetical title associated by foreign countries with the sovereign of Japan; the Japanese title, corresponding to "emperor," is *tenno*, the term *kotei* being used of his function in relation to external affairs. By the constitution of 1889, the emperor of Japan transferred a large part of his former powers as absolute monarch to the representatives of the people, but as head of the empire he appoints the ministers, declares war, makes peace and concludes treaties, acting generally as a constitutional sovereign but with all the personal authority attaching to his august position. The history of the mikados goes back to very early times; but from 1600 to 1868 the real power was in the hands of the shoguns, who nevertheless were in ceremonial theory always successively invested with their authority by the mikado. The revolution of 1867 restored the real power into the mikado's hands. (See Japan: *History*; and Mutsu-Hito.)

MIKIRS, a hill tribe of India, occupying two or three detached tracts in Nowgong and Sibsagar districts of Eastern Bengal and Assam, known as the Mikir hills. In 1901 their total number was returned as 87,056. Mikir is the name given to them by the Assamese; they call themselves Arleeng, which means "man" in general. They have long settled down to agriculture, and are distinguished from the tribes around them by the absence of savagery. Their language, which has been studied by missionaries, seems to connect them with the Kuki-Chin stock on the Burmese frontier.

See Sir C. Lyall, *The Mikirs* (1908).

MIKLOSICH, FRANZ VON (1813–1891), Austrian philologist, was born at Luttenberg, Styria, on the 29th of November 1813. He graduated at the university at Gratz as a doctor of philosophy, and was for a time professor of philosophy there. In 1838 he went to Vienna, where he took the degree of doctor of law. He devoted himself, however, to the study of Slavonic languages, abandoned the law, and obtained a post in the imperial library, where he remained from 1844 to 1862. In the former year he published a noteworthy review of Bopp's *Comparative Grammar*, and this began a long series of works of immense erudition which completely revolutionized the study of Slavonic languages. In 1849 Miklosich was appointed to the newly created chair of Slavonic philology at the university of Vienna, and he occupied it until 1886. He became a member of the Academy of Vienna, which appointed him secretary of its historical and philosophical section, a member of the council of public instruction and of the upper house, and correspondent of the French Academy of Inscription. His numerous writings deal not only with the Slav languages, but with Rumanian, Albanian, Greek, and the language of the gypsies. Miklosich died on the 7th of March 1891.

MILAN (Ital. *Milano*, Ger. *Mailand*, anc. *Mediolanum*, *q.v.*), a city of Lombardy, Italy, capital of the province of Milan, 93 m. by rail E.N.E. of Turin. Pop. (1881), 321,839; (1906), 560,613. It is the seat of an archbishop, the headquarters of the II. army corps, the chief financial centre of Italy and the wealthiest manufacturing and commercial town in the country. It stands on the little river Olona, near the middle of the Lombard plain, 400 ft. above sea-level.

The plain around Milan is extremely fertile, owing at once to the richness of the alluvial soil deposited by the Po, Ticino, Olona and Adda, and to the excellent system of irrigation. Seen from the top of the cathedral, the plain presents the appearance of a vast garden divided into square plots by rows of mulberry or poplar trees. To the east this plain stretches in an unbroken level, as far as the eye can follow it, towards Venice and the Adriatic; on the southern side the line of the Apennines from Bologna to Genoa closes the view; to the west rise the Maritime, Cottian and Graian Alps, with Monte Viso as their central point; while northward are the Pennine, Helvetic and Rhaetian Alps, of which Monte Rosa, the Saasgrat and Monte Leone are the most conspicuous features. In the plain itself lie many small villages; and here and there a larger town like Monza or Saronno, or a great building like the Certosa of Pavia, makes a white point upon the greenery. The climate is changeable and trying; in summer it is intensely hot, in winter very cold. Snow is often seen, and the thermometer is frequently below freezing-point.

In shape Milan is a fairly regular polygon, and its focus is the splendid Piazza del Duomo, from which a number of broad modern streets radiate in all directions. These streets are connected by an inner circle of boulevards, constructed just outside the canal, which marks the site of the town moat. The arches of Porta Nuova are almost the last trace of the inner circuit, constructed after the destruction of the city by Frederick Barbarossa, to which also belonged the Porta dei Fabbri, demolished in 1900. Curious reliefs from the Porta Romana are to be seen in the museum. Within this circle the majority of the streets are narrow and crooked, while those between it and the bastions, though broader on the whole, have but little regularity. An outer circle of boulevards, planted with trees and commanding the view of the suburbs, lies just beyond the present walls of the city, erected by the Spaniards in the 16th century; the entire length of these boulevards is traversed by an electric tramway 7 m. long.

Occupying one end of the Piazza del Duomo is the famous cathedral. It is built of brick cased in marble from the quarries which Gian Galeazzo Visconti gave in perpetuity to the cathedral chapter. It was begun in 1386. The name of the original architect is unknown, but it is certain that many German master-masons were called to Milan to assist the Italian builders. It was then the largest church in existence, and now, after St Peter's at Rome and the cathedral of Seville, the Duomo of Milan is the largest church in Europe; it covers an area of 14,000 sq. yds. and can hold 40,000 people. The interior is 486 ft. long, 189 ft. wide; the nave is 157 ft. high, and the distance from the pavement to the top of the tower is 356 ft. The style is Gothic, very elaborately decorated, but it shows many peculiarities, for the work was continued through several centuries and after many designs by many masters, notably by Amadeo, who carried out the octagonal cupola (the pinnacle of which dates from 1774), and by Tibaldi, who laid down the pavement and designed a baroque façade. This last feature was begun after Tibaldi's design in 1615, but was not finished till 1805, when Napoleon caused the work to be resumed. With its Renaissance windows and portals this façade, though good in itself, was utterly out of keeping with the general style of the church, and in 1900 the removal of the inharmonious features was begun, to be replaced in a style strictly in accordance with the Gothic style of the rest of the building from the designs of Giuseppe Brentano. In shape the church is cruciform, with double aisles to the nave and aisles to the transepts. The roof is supported by fifty-two pillars with canopied niches for statues instead of capitals; the great windows of the choir, reputed to be the largest in the world, are filled with stained glass of 1844. To the right of the entrance is the tomb of Archbishop Heribert, the champion of Milanese liberty, while beside him rests Archbishop Otto Visconti, the founder of that family as a reigning house. The large bronze candelabrum in the left transept is said to be 13th century work. In a crypt under the choir lies the body of the cardinal saint Carlo Borromeo, who consecrated the cathedral in 1577. It is contained in a rock-crystal shrine, encased in silver, and is vested in full pontifical robes blazing with jewels. The roof of the cathedral is built of blocks of marble, and the various levels are reached by staircases carried up the buttresses; it is ornamented with a profusion of turrets, pinnacles and statues, of which last there are said to be no fewer than 4440, of very various styles and periods. In front of the cathedral rises a colossal bronze equestrian statue of Victor Emmanuel II.

There are two noteworthy palaces in the Piazza del Duomo. The first is the Palazzo Reale dating from 1772, but occupying the site of the earliest mansion of the Viscontis and the Sforza; its great hall is a handsome chamber with a gallery supported by caryatides. Built into the palace is the ancient church of San Gottardo, a Romanesque building which was built by Azzone Visconti in 1328–1339, and was the scene of the murder of Giovanni Maria Visconti in 1412. Its campanile is a beautiful example of early Lombard terra-cotta work. The second palace is that of the archbishops, the fine façade of which is the work of Fabio Magnone. It has an older north colonnade, by some attributed to Bramante, but, like many other buildings, without sufficient evidence, and a fine court with double colonnades by Tibaldi, to whom the back façade is due. The Palazzo della Ragione, erected in the Piazza dei Mercanti, just west of the Piazza del Duomo, the central point of the medieval city, in 1223–1238 by the podestà, Oldrado da Tresseno, whose equestrian portrait in high relief adorns it, still exists in fine preservation. It is a brick edifice with a portico on the ground floor and a large hall on the upper. Close by to the south is the beautiful Loggia degli Osii, erected in 1316, with two loggie or open porticos, one above the other, in black and white marble.

Among the most interesting buildings in Milan is the ancient church of S. Ambrogio. Here St Ambrose baptized St Augustine; here he closed the doors against the emperor Theodosius after his cruel massacre at Thessalonica; here the Lombard kings and the early German emperors caused themselves to be crowned with the iron crown of Lombardy, and the pillar at which they took their coronation oaths is preserved under the lime-trees in the piazza. The church was built by St Ambrose early in the 4th-century (on the site of a temple of Bacchus it is said), but as it stands it is a Romanesque basilica of the 12th century, recently well restored (like many other churches in Milan), with a brick exterior, like so many churches of Milan and Lombardy, curious galleries over the façade, and perhaps the most perfectly preserved atrium in existence. The wooden door belongs to the original 4th century church; it has carvings with scenes from the life of David. In a great silver reliquary (modern) in the crypt lie the bones of St Ambrose, above which rises the high altar, which retains its original decorations, the only intact example of its period (835). These consist of reliefs in gold and silver enriched with enamel and gems, and are the work of one Vuolfvinus, a German. The baldacchino, with sculptures of the 12th or early 13th century, is borne by four ancient columns of porphyry, with 9th-century capitals. In the tribune are fine mosaics of the 9th century, which, Burckhardt remarks, completely break with Byzantine tradition. In the side chapel of S. Satiro are even earlier mosaics (5th century); there are also fine frescoes by Borgognone and Bernardino Lanini. The lofty brick campanile (789–824) is among the earliest in Italy, and is decorated with coloured majolica disks. The court of the neighbouring canonica is by Bramante, and so also may be the design of the cloisters of the monastery of S. Ambrogio, now the military hospital. S. Lorenzo, in the south portion of the town, dates from before A.D. 538, thus being practically contemporary with S. Vitale at Ravenna (though Burckhardt considers it to belong to about A.D. 300, and to be a part of the thermae or palace of Maximian), but was burnt down and restored in 1071 (in the restoration Corinthian capitals were used as bases). Thirty-three years later part of it collapsed, and a second fire followed in 1124. It was restored, but collapsed again in 1573, and a great part of it had to be reconstructed, including the dome (1574–1591). (The chapel of S. Aquilino, possibly a part of the original structure, contains mosaics of the 5th or 6th century.) In plan the church is an octagon, supported at the corners by four square towers in brickwork, which belong to the original structure. The interior with its two orders is a very fine one, and its influence on Renaissance architects has been very considerable. S. Eustorgio, one of the largest Gothic churches in Milan, with some Romanesque survivals, dates, as it stands, with its campanile, from the end of the 13th century, and has a modern façade in the old style. It has some interesting medieval works of sculpture, and a fine chapel (Cappella Portinari), with a good dome and a beautiful frieze of angels, built by Michelozzo in 1462–1468, and containing the splendid sculptured tomb (a marble sarcophagus with reliefs, supported by statues) of Peter Martyr (*q.v.*), the masterpiece of Giovanni di Balduccio of Pisa (1339); the walls of the chapel are decorated with important frescoes by Vincenzo Foppa of Brescia. S. Simpliciano, too, though originally Romanesque, is now in the main Gothic, and has been much altered.

S. Vincenzo in Prato (833), now restored to its basilican form, with nave and two aisles divided by columns and three apses, and with small, flat arcading on the exterior, which is in brickwork; S. Satiro, founded in 879; S. Babila, also restored to its original form, &c., are interesting for their Romanesque architecture. The small domed structure on the left of S. Satiro is earlier than the church, while the campanile is part of the original structure, though preceded in date by that of S. Ambrogio, which is one of the earliest genuine campanili in Italy (789–824). The reconstruction of the church of S. Satiro was Bramante's earliest work in Milan (after 1476). The choir is painted in perspective (there was no room to build one), the earliest example of this device, which was so frequently used in baroque architecture. The octagonal sacristy (before 1488), with niches below and a gallery above, with stucco decorations by Bramante himself (the frieze with putti and medallions is ascribed to Caradosso), is a masterly work, and one of his best. The Cistercian abbey-church of Chiaravalle, 5½ m. south of Milan, is a fine brick building in the plan of a Latin cross, with nave and two aisles with round pillars, with a lofty domed tower, in the so-called Romanesque Transition style, having comparatively slender round pillars and cross vaulting, while the exterior is still quite Romanesque. It was founded in 1135 by St Bernard and consecrated in 1221. It is interesting as the model for the plan of many other churches in Lombardy, *e.g.* S. Maria del Carmine and

S. Francesco in Pavia. S. Marco, modernized inside, still retains a beautiful façade of 1254 and a tower—in brick as elsewhere—and contains another tomb by Balduccio. S. Maria Incoronata is unique as a double Gothic church, in the horizontal sense (1451–1487).

Of the secular buildings of the beginning of the 15th century, the most notable is the Palazzo Borromeo, which still preserves its Gothic courtyard. It has a good collection of Lombard pictures. At no great distance from S. Ambrogio, in the Corso Magenta, is the church of Santa Maria delle Grazie, built by the Dominicans about 1460, to which the Gothic façade and nave belong. The choir, crossing, and beautiful sixteen-sided dome, with the elegant external decorations in terra-cotta and marble, are by Bramante (*c.* 1492). Adjoining the church is the convent, long used as barracks. Leading from the fine cloisters, also the work of Bramante, is the former refectory, on the walls of which Leonardo da Vinci painted his celebrated "Last Supper," a work which is unfortunately in a bad state of preservation.

Farther along the Corso, but nearer the Piazza del Duomo, is San Maurizio, the interior of which is covered by exceedingly effective frescoes by Luini and his contemporaries. The interior was erected by Giovanni Dolcebuono, a pupil of Bramante, to whom is also due S. Maria presso S. Celso (the interior and the baroque façade are by Alessi). Thence the Via Bollo leads to the Piazza della Rosa, in which is situated the renowned Biblioteca Ambrosiana, erected in 1603–1609 by Fabio Manzone, to whom the Palazzo del Senato is also due, rich in MSS. In the same building there is also a picture gallery, in which is Raphael's cartoon for his fresco the "School of Athens" in the Vatican. Situated just within the Naviglio, the canal encircling the inner town (adjacent to San Nazaro, which contains Bernardino Lanini's [*fl.* 1546] masterpiece, the "Martyrdom of St Catherine"), is the Ospedale Maggiore. This institution, which can accommodate 2400 patients, was founded in the reign of Francesco Sforza. The principal court (there are nine in all) is surrounded by fine arcades of the 17th century by Ricchini. The entire edifice is covered externally with terra-cotta, and its façade, designed by the Florentine Antonio Averulino (Filarete) and begun in 1457, is superior to any other of the kind in Milan.

The city is rich in works of art, for Milan, with the introduction of the early Renaissance style by Filarete and Michelozzo after 1450, became the home of a Lombard school of sculpture, among the chief masters of which may be mentioned Giovanni Antonio Amadeo, or Omodeo,[1] of Pavia (1447–1522), Cristoforo Solari, and, the last of them, Agostino Busti, known as Bambaia (*c.* 1480–1548), whose work may be seen in the cathedrals of Como and Milan and in the Certosa di Pavia. Subsequently, towards the close of the 15th century, the refined court of Lodovico Sforza attracted such celebrated men as Bramante, the architect, Gauffino Franchino, the founder of one of the earliest musical academies, and Leonardo da Vinci, from whose school came Luini, Boltraffio, Gaudenzio Ferrari, Marco d'Oggiono, &c. Later, Pellegrino Tibaldi and Galeazzo Alessi of Genoa (the former a man of very wide activity) were the chief architects, and Leone Leoni of Arezzo the chief sculptor. In still more recent times Beccaria (1738–1794) as a jurist, Monti (1754–1828) as a poet and Manzoni (1785–1873) as a novelist, have won for the Milanese a high reputation.

The picture gallery of the Brera, one of the finest in Italy, occupies an imposing palace with a good courtyard by Ricchini. It was built as a Jesuit college in 1651, but since 1776 has been the seat of the Accademia di Belle Arti, and contains besides the picture gallery a library of some 300,000 volumes, a collection of coins numbering about 60,000, and an excellent observatory founded in 1766. The Brera Gallery, the nucleus of which was formed in 1806, possesses Raphael's famous "Sposalizio," and many pictures and frescoes by Luini, Guadenzio Ferrari and Bramantino; the collection of the works of Carlo Crivelli (*fl.* 1480) affords an instructive survey of his work, which connects the Paduan school with the Venetian, here particularly well represented by works of Paolo Veronese, Paris Bordone, Gentile Bellini, Cima da Conegliano, Bonifazio, Moroni and Carpaccio. Additions are continually made to it.

The Castel Sforzesco, or Castle of Milan, stands in the Parco Nuovo; it was built in 1450 by Francesco Sforza on the site of one erected by Galeazzo II. Visconti (1355–1378) and demolished in 1447 by the populace after the death of Filippo Maria Visconti. After suffering many vicissitudes and being partially destroyed more than once, it was restored—including especially the splendid entrance tower by Antonio Averulino (Filarete, 1451–1453), destroyed by a powder explosion in 1521—in the 15th-century style in 1893 sqq., and it is now a most imposing pile. Some of the fine windows with their terra-cotta decorations are preserved. The archaeological museum is housed here on the ground floor; besides Roman and pre-Roman objects it contains fragments of the 9th century basilica of Santa Maria in Aurona, one of the first examples of vaulted Lombard architecture; the bas-reliefs of the ancient Porta Romana of Milan, representing the return of the Milanese in 1171 after the defeat of Barbarossa; the remains of the church of Santa Maria in Brera, the work of Balduccio da Pisa; the grandiose sepulchral monument of Bernabò Visconti formerly in the church of San Giovanni in Conca; the tomb of Regina della Scala, the wife of Bernabò; the funeral monument of the Rusca family; the great portal of the palace of Pigello Portinari, seat of the Banco Mediceo at Milan, a work of Michelozzo; a series of Renaissance sculptures, including works by Amadeo Mantegazza, Agostino Busti (surnamed Bambaia), including fragments of the tomb of Gaston de Foix. Several of the rooms occupied by the archaeological museum bear traces of the decorations executed under Galeazzo Maria and Lodovico il Moro, and one of them has a splendid ceiling with trees in full foliage, painted so as to cover the whole vaulting, ascribed to Leonardo da Vinci. In the upper rooms is placed a large collection of Milanese and central Italian ceramics, stuffs, furniture, bronzes, ivories, enamels, glass and historical relics; together with a picture gallery containing works by Vincenzo Foppa, Gianpietrino, Boltraffio, Crivelli, Pordenone, Morone, Cariani, Correggio, Antonello da Messina, Tiepolo, Guardi, Potter, Van Dyck and Ribeira.

The finest of the modern thoroughfares of Milan is the Via Dante, constructed in 1888; it runs from the Piazza de' Mercanti to the spacious Foro Bonaparte, and thence to the Parco Nuovo, the great public garden in which stands the Castello Sforzesco. This park was once a national drilling ground, which was taken over by the municipality with a view to erecting upon it a new residential quarter, rendered necessary by the phenomenal growth of the city during the last twenty-five years of the 19th century. This design was happily abandoned, and around the Parco Nuovo has grown up a new quarter of wide streets, spacious gardens and private villas.

To the north of the castle is the Arena, a kind of circus erected by Napoleon in 1805; while facing the castle on the opposite side of the park is the Arco della Pace, begun by Napoleon in 1806 from the designs of Cagnola to mark the beginning of the Simplon Road, but finished by the Austrians in 1833. Leading east-north-east from the Piazza del Duomo, the centre of Milanese traffic, especially of electric trams, is the Corso Vittorio Emanuele. Connecting the piazza with the neighbouring Piazza della Scala is the famous Galleria Vittorio Emanuele, a great arcade in the form of a Latin cross, with an octagon in the centre, crowned at the height of 160 ft. with a glass cupola; it is roofed with glass throughout, and is 320 yds. long, 16 yds. wide and 94 ft. high. It has splendid façades at each end, and was constructed in 1865–1867 at the cost of £320,000; it is the finest of its kind in Europe.

In the Via Morone near the Piazza della Scala is a collection of art treasures bequeathed to the town in 1879 by a Milanese patrician, the Cavaliere Poldi-Pezzoli. It comprises valuable pictures, textile fabrics, arms, armour and a number of antiquities, and is exhibited in the house once occupied by the founder. In the middle of the neighbouring Piazza della Scala stands Magni's monument of Leonardo da Vinci (1872). Opposite is the celebrated Teatro della Scala, built in 1778 on the site of a church founded by Beatrice della Scala, wife of Bernabò Visconti. After the San Carlo at Naples it is the largest theatre in Europe, and can seat 3600 spectators. Looking on to the piazza is the fine Palazzo Marino, the seat of the municipality since 1861; it was built by Galeazzo Alessi in 1558, to whom the side façade and the court are due, but was not completed until 1890, when the main façade was erected by Luca Beltrami. S. Fedele by Tibaldi (1569) is close by. Milan has a royal scientific and literary academy with a faculty of philosophy, a royal technical institute, a school of veterinary science, a royal school of agriculture, a polytechnic with the Bocconi commercial school (founded 1898) and numerous other learned and educational institutions. Milan has long been famous as one of the great musical centres of Europe, and numerous students resort here for their musical education. There are many philanthropic institutions, the most interesting of which is the Albergo Popolare, an establishment conducted on lines similar to the houses established in England by Lord Rowton in 1894. Sport and athletics are provided by a number of clubs, notably the Touring Club Italiano, founded in 1894.

---

[1] See F. Malaguzzi Valeri, *G. A. Amadeo, scultore e architetto* (Bergamo, 1905).

The modern industrial development of Milan, with its suburbs and neighbouring towns, such as Monza, Gallarate, Saronno, Busto Arsizio and Legnano, has been noteworthy. Machine-making on a large scale is carried on by firms widely celebrated for the construction of locomotives, railway trucks and carriages, steam-boilers and motors, turbines, pumps, metal bridges and roofs. Minor industries are represented by workshops for the production of surgical, musical and geodetic instruments; of telephone and telegraph accessories; dynamos, sewing-machines, bicycles and automobiles. There is also a large carriage industry. In textile industries silk holds the first place. The amount of silk handled and woven in Milan is greater than that dealt with at Lyons. Spinning and twisting are as highly developed as the weaving industry. Milan is also the centre of the Italian cotton industry. Cotton-weaving, dyeing and printing are extensively carried on. Linen, flax, jute and wool are also spun and woven. The Milanese manufactures of articles in caoutchouc and of electric cables have acquired a world-wide reputation. In typography Milan is renowned principally for its musical editions and for its heliotype and zincotype establishments. There is, besides, a huge production of posters for advertisement. The manufacture of furniture of all kinds is still extensively carried on, Milan being the chief Lombard market and centre of exportation. The towns of Cantu, Meda, Lissone and Carugo supply Milanese firms with most of their merchandise, the furniture being made by the workmen at their own homes with materials supplied by the Milanese buyers, who also advance the capital necessary for working expenses. Theatrical costumes and appliances are also made in Milan, which is an important theatrical centre. House industry is still widely diffused in Milan itself, especially as regards working in gold, silver, vulcanite, bronze and leather. The motive power for much of the house industry is supplied by electricity. The electricity is partly furnished by hydraulic works at Paderno, 24 m. from Milan; the horse-power is continually being increased owing to new needs. Gas is also much used. Milan is also a centre of the export trade in cheese; chocolate, biscuits, &c., are also manufactured.

The municipal schools of Milan are as well organized as any in Italy, and the exhibit in connexion with them at the great international exhibition of 1906 was of interest. There were, in 1907, 76 buildings for schools and 47,968 pupils, while in the evening and holiday classes there were 10,724 older pupils; 2,109,920 free rations and 215,135 paid rations were distributed to 16,526 pupils, and douches were supplied. Pizzoli's Tavolo Psicoscopico for examining the mental qualities of the pupils is of interest. The international exhibition of 1906 held in Milan was of considerable importance, all the leading states of the world taking part in it. The retrospective exhibition of means of transport was interesting in view of the recent opening of the Simplon tunnel, the occasion of the exhibition. Among the most noteworthy exhibits were those of machinery, of automobiles and bicycles, of agriculture, of transports by sea, of modern art and architecture, of Italian home industries, of the city of Milan; besides which, all the countries exhibiting had their own separate pavilions.

Until 1898 the octroi circle did not extend beyond the walls; but in that year it was found necessary, owing to the growth of the city and of municipal expenditure, to include the external quarters or Corpi Santi (a name also applied to the extramural portions of Cremona and Pavia), with their large industrial population. Since that time municipal finance has been in a prosperous condition.

The water supply, from wells some 150 ft. deep in the sub-soil, is fairly good; one of the towers of the Castello Sforzesco is used as a distributing centre, while the sewerage system consists of 48 m. of sewers on the single channel principle, with collectors discharging into the Vettabia, a tributary of the Lambro.

In 1860 a large cemetery, the Cimitero Monumentale, was opened, but found to be insufficient, it is reserved for important monuments, that of Musocco, 3 m. from the city, being used for general purposes.

History—(For earlier history see MEDIOLANUM).—After the establishment of the Lombard capital at Pavia in 569 Milan remained the centre of Italian opposition to the foreign conquest. The Lombards were Arians, and the archbishops of Milan from the days of Ambrose had been always orthodox. Though the struggle was unequal, their attitude of resolute opposition to the Lombards gained for them great weight among the people, who felt that their archbishop was a power around whom they might gather for the defence of their liberty and religion. All the innate hatred of the foreigner went to strengthen the hands of the archbishops, who slowly acquired, in addition to their spiritual authority, powers military, executive and judicial. These powers they came to administer through their delegates, called viscounts. When the Lombard kingdom fell before the Franks under Charlemagne in 774, the archbishops of Milan were still further strengthened by the close alliance between Charles and the Church, which gave a sort of confirmation to their temporal authority, and also by Charles's policy of breaking up the great Lombard fiefs and dukedoms, for which he substituted the smaller counties. Under the confused government of Charles's immediate successors the archbishop was the only real power in Milan. But there were two classes of difficulties in the situation, ecclesiastical and political; and their presence had a marked effect on the development of the people and the growth of the commune, which was the next stage in the history of Milan. On the one hand the archbishop was obliged to contend against the heretics or against fanatical reformers who found a following among the people; and on the other, since the archbishop was the real power in the city, the emperor, the nobles and the people each desired that he should be of their party; and to whichever party he did belong he was certain to find himself violently opposed by the other two. From these causes it sometimes happened that there were two archbishops, and therefore no central control, or no archbishop at all, or else an archbishop in exile. The chief result of these difficulties was that a spirit of independence and a capacity of judging and acting for themselves was developed in the people of Milan. The terror of the Hunnish invasion, in 899, further assisted the people in their progress towards freedom, for it compelled them to take arms and to fortify their city, rendering Milan more than ever independent of the feudal lords who lived in their castles in the country. The tyranny of these nobles drove the peasantry and smaller vassals to seek the protection for life and property, the equality of taxation and of justice, which could be found only inside the walled city and under the rule of the archbishop. Thus Milan grew populous, and learned to govern itself. Its inhabitants became for the first time Milanese, attached to the standard of St Ambrose—no longer subjects of a foreign conqueror, but a distinct people, with a municipal life and prospects of their own. For the further growth of the commune, the action of the great archbishop, Heribert (1018–1045), the establishment of the carroccio, the development of Milanese supremacy in Lombardy, the destruction of Lodi, Como, Pavia and other neighbouring cities, the exhibition of free spirit and power in the Lombard league, and the battle of Legnano, see the articles ITALY and LOMBARDS. In 1157 an almost circular moat, still preserved in the inner canal or Naviglio, was constructed round the town; but in 1162 Frederick Barbarossa took and almost entirely destroyed the city, only a few churches surviving. The city with its walls was, however, rebuilt five years later by the allied cities of Bergamo, Brescia, Mantua and Verona.

After the battle of Legnano, in 1174, although the Lombard cities failed to reap the fruit of their united action, and fell to mutual jealousy once more, Milan internally began to grow in material prosperity. After the peace of Constance (1183) the city walls were extended; the arts flourished, each in its own quarter, under a syndic who watched the interests of the trade. The manufacture of armour was the most important industry. During the struggles with Barbarossa, when freedom seemed on the point of being destroyed, many Milanese vowed themselves, their goods and their families to the Virgin should their city come safely out of her troubles. Hence arose the powerful fraternity of the "Umiliati," who established their headquarters at the Brera, and began to develop the wool trade, and subsequently gave the first impetus to the production of silk. From this period also date the irrigation works which render the Lombard plain a fertile garden. The government of the city consisted of (*a*) a parlamento or consiglio grande, including all who possessed bread and wine of their own—a council soon found to be unmanageable owing to its size, and reduced first to 2000, then to 1500 and finally to 800 members; (*b*) a credenza or committee of 12 members, elected in the grand council, for the despatch of urgent or secret business, (*c*) the consuls, the executive, elected for one year, and compelled to report to the great council at the term of their office.

The bitter and well-balanced rivalry between the nobles and the people, and the endless danger to which it exposed the city owing to the fact that the nobles were always ready to claim the protection of their feudal chief, the emperor, brought to the front two noble families as protagonists of the contending factions—the Torriani of Valsassina, and the Visconti, who derived their name from the office of delegates which they had held under the archbishops. After the battle of Cortenova, in 1237, where Frederick II. defeated the Guelph army of the Milanese and captured their carroccio, Pagano della Torre rallied and saved the remnants of the Milanese. This act recommended him to popular favour, and he was called to the government of the city—but only for the distinct purpose of establishing the "catasta," a property tax which should fall with equal incidence on every citizen. This was a democratic measure which marked the party to which the Torriani belonged and rendered them hateful to the nobility. Pagano died in 1241. His nephew Martino followed as podestà in 1256, and in 1259 as signore of Milan—the first time such a title was heard in Italy. The nobles, who had gathered round the Visconti, and who threatened to bring Ezzelino da Romano, the Ghibelline tyrant of Padua, into the city, were defeated by Martino, and 900 of their number were captured. Martino was followed by two other Torriani, Filippo his brother (1263–1265) and Napoleone his cousin (1265–1277), as lords of Milan. Napoleone obtained the title of imperial vicar from Rudolph of Hapsburg. But the nobles under the Visconti had been steadily gathering strength, and Napoleone was defeated at Desio in 1277. He ended his life in a wooden cage at Castel Baradello above Como.

Otto Visconti, archbishop of Milan (1262), the victor of Desio, became lord of Milan, and founded the house of Visconti, who ruled the city—except from 1302 to 1310—till 1447, giving twelve lords to Milan. Otho (1277–1295), Matteo (1310–1322), Galeazzo (1322–1328), Azzo (1328–1339), Lucchino (1339–1349) and Giovanni (1349–1354) followed in succession. Giovanni left the lordship to three nephews—Matteo, Galeazzo and Bernabò. Matteo was killed (1355) by his brothers, who divided the Milanese, Bernabò reigning in Milan (1354–1385) and Galeazzo in Pavia (1354–1378). Galeazzo left a son, Gian Galeazzo, who became sole lord of Milan by seizing and imprisoning his uncle Bernabò. It was under him that the cathedral of Milan and the Certosa di Pavia were begun. He was the first duke of Milan, having obtained that title from the emperor Wenceslaus. His sons Giovanni Maria, who reigned at Milan (1402–1412), and Filippo Maria, who reigned at Pavia (1402–1447), succeeded him. In 1412, on his brother's death, Filippo united the whole duchy under his sole rule, and attempted to carry out his father's policy of aggrandizement, but without success.

Filippo was the last male of the Visconti house. At his death a republic was proclaimed, which lasted only three years. In 1450 the general Francesco Sforza, who had married Filippo's only child Bianca Visconti, became duke of Milan by right of conquest if by any right. Under this duke the castello was rebuilt and the canal of the Martesana, which connects Milan with the Adda, and the Great Hospital were carried out. Francesco was followed by five of the Sforza family. His son Galeazzo Maria (1466–1476) left a son, Gian Galeazzo, a minor, whose guardian and uncle Lodovico (il Moro) usurped the duchy (1479–1500). Lodovico was captured in 1500 by Louis XII. of France, and Milan remained for twelve years under the French crown. In the partial settlement which followed the battle of Ravenna, Massimiliano Sforza, a protégé of the emperor, was restored to the throne of Milan, and held it by the help of the Swiss till 1515, when Francis I. of France reconquered the Milanese by the battle of Marignano, and Massimiliano resigned the sovereignty for a revenue from France. This arrangement did not continue. Charles V. succeeded the emperor Maximilian, and at once disputed the possession of the Milanese with Francis. In 1522 the imperialists entered Milan and proclaimed Francesco Sforza (son of Lodovico). Francesco died in 1535, and with him ended the house of Sforza. From this date till the War of the Spanish Succession (1714) Milan was a dependency of the Spanish crown. At the close of that war it was handed over to Austria; and under Austria it remained till the Napoleonic campaign of 1796. For the results of that campaign, and for the history of Italian progress towards independence, in which Milan played a prominent part by opening the revolution of 1848, with the insurrection of the Cinque Giornate (March 17–22), by which the Austrians were driven out; the reader is referred to the article ITALY. The Lombard campaign of 1859, with the battles of Solferino and Magenta, finally made Milan a part of the kingdom of Italy.

Ady, *A History of Milan under the Sforza* (1907). (H. F. B.; T. As.)

MILANESI, GAETANO (1813–1895), Italian scholar and writer on the history of art, was born at Siena, where he studied law, and in 1838 he obtained an appointment in the public library. In 1856 he was elected member of the Accademia della Crusca, in which capacity he took part in the compilation of its famous but still unfinished dictionary, and two years later was appointed assistant keeper of the Tuscan archives, in Florence; then he took charge of the famous Medici archives, whence he collected a vast body of material on the history of Italian art, not all of which is yet published. In 1889 he became director of the archives, but retired in 1892, and died three years later. His most important publication is his edition of Vasari's works in nine volumes, with copious and valuable notes (Florence, 1878–1885). Of his other writings the following may be mentioned: *Il diario inedito di Alessandro Sozzini* (in the *Archivio storico Italiano*, 1842); *Documenti per la storia dell' arte senese*, 3 vols. (Siena, 1854–1856) and *Discorsi sulla storia civile ed artistica di Siena* (Siena, 1862). He also edited a number of Italian classics.

See E. Ridolfi's article in the *Nuova antologia* (May 15, 1895); and A. Virgili's article in the *Atti della regia Accademia della Crusca* (Florence, 1895).

MILAN OBRENOVICH IV. (1854–1901), king of Servia, was born on the 22nd of August 1854, at Jassy. He was the grand-nephew of the famous Milosh, whose brother Jefrem (d. 1856) had a son, Milosh (1829–1861), who married Maria Katardži, a Moldavian. Milan was their son. While still very young, he lost both his parents, and was adopted by his cousin, Michael Obrenovich, who returned to Servia on the expulsion of the Karageorgeviches in 1858 and became ruling prince on the death of his father, Milosh, in 1860. During the reign of Michael young Milan was educated in Paris, at the Lycée Louis-le-Grand, where he displayed considerable precocity, but he was only fourteen years of age when in 1868 his cousin was assassinated and he succeeded to the throne under a regency. In 1872 he was declared of age, and taking the reins of government into his own hands, soon manifested great intellectual power, coupled with a passionate headstrong character. Eugene Schuyler, who saw him about this time, found him "a very remarkable young man . . . singularly intelligent and well-informed." By a careful balancing of the Austrian and Russian parties in Servia, with a judicious leaning towards the former, Prince Milan was enabled in 1878, at the end of the Turkish War, to induce the Porte to acknowledge his independence, and was proclaimed king in 1882. (The history of his reign is told in detail under SERVIA.) Acting under Austrian influence, King Milan devoted all his energies to the improvement of means of communication and the development of natural resources, but the cost, which was unduly increased by reckless extravagance, led to proportionately heavy taxation. This, coupled with increased military service, rendered King Milan and the Austrian party most unpopular; and his political troubles were further increased by the defeat of the Servians in the war against Bulgaria, 1885–86. In 1885 (Sept.) the union of Rumelia and Bulgaria caused widespread agitation in Servia, and Milan precipitately declared war upon his kinsman Prince Alexander on the 15th of November. After a short but decisive campaign, the Servians were utterly routed at the battles of Slivinska and Pirot, and Milan's throne was only saved by the direct intervention of Austria. Domestic difficulties now arose which rapidly assumed a political significance. In October 1875 King Milan had married Natalie, the sixteen-years-old daughter of Peter Ivanovich Ketchko, a Moldavian Boyar, who was a colonel in the Russian army, and whose wife, Pulcheria, was by birth Princess Sturdza. A son, Alexander, was born in 1876, but the king and queen showed signs of friction. Milan was anything but a faithful husband. Queen Natalie was greatly influenced by Russian sympathies; and the couple, ill-assorted both personally and politically, separated in 1886, when the queen withdrew from the kingdom, taking with her the young prince, Alexander, afterwards king, then ten years of age. While she was residing at Wiesbaden in 1888, King Milan succeeded in recovering the crown prince, whom he undertook to educate; and in reply to the queen's remonstrances, he exerted considerable pressure upon the metropolitan, and procured a divorce, which was afterwards annulled as illegal. King Milan now seemed master of the situation, and on the 3rd of January 1889 promulgated a new constitution much more liberal than the existing one of 1869. Two months later (March 6) he suddenly abdicated in favour of his son, a step for which no satisfactory reason was assigned, and settled as a private individual in Paris. In February 1891 a Radical ministry was formed, Queen Natalie and the ex-metropolitan Michael returned to Belgrade, and Austrian influence began to give way to Russian. Fear of a revolution and of King Milan's return led to a compromise, by which in May 1891 the queen was expelled, and Milan was allowed a million francs from the civil list, on condition of not returning to Servia during his son's minority. Milan in March 1892 renounced all his rights, and even his Servian nationality. The situation altered, however, after the young King Alexander in April 1893 had effected his *coup d'état* and taken the reins of government into his hands. Servian politics began to grow more complicated, and Russian intrigue was rife. In January 1894 Milan suddenly appeared at Belgrade, and his son gladly availed himself of his experience and advice. On the 29th of April a royal decree reinstated Milan and Natalie, who in the meantime had become ostensibly reconciled, in their position as members of the royal family. On the 21st of May the constitution of 1869 was restored, and Milan continued to exercise considerable influence over his son. The queen, who had been residing chiefly at Biarritz, returned to Belgrade in May 1895, after four years' absence, and was greeted by the populace with great enthusiasm. In 1897 Milan was appointed commander-in-chief of the Servian army. In this capacity he did some of the best work of his life, and his success in improving the Servian military system was very marked. His relations with the young king also remained good, and for a time it seemed as though all Russian intrigues were being checked. The good relations between father and son were interrupted, however, by the latter's marriage in July 1900. Milan violently opposed the match, and resigned his post as commander-in-chief; and the young king banished him from Servia and threw himself into the arms of Russia. Milan retired to Vienna, and there he died unexpectedly on the 11th of February 1901. Milan was an able, though headstrong man, but he lived a scandalously irregular life, and was devoid of moral principle. In considering his relations with his young son, it must be remembered that in the dynastic and political condition of Servia natural feeling was inevitably subordinated in Milan to other considerations. (H. Ch.)

MILÁ Y FONTANALS, MANUEL (1818–1884), Spanish scholar, born at Villafranca del Panadés, near Barcelona, on the 4th of May 1818, was educated first at Barcelona, and afterwards at the university of Cervera. In 1845 he became professor of literature at the university of Barcelona, and held this post till his death at Villafranca del Panadés on the 16th of July 1884. The type of the scholarly recluse, Milá y Fontanals was almost unknown outside the walls of the university till 1859, when he was appointed president of the *juegos florales* at Barcelona. On the publication of his treatise, *De Los trovadores en España* (1866), his merits became more generally recognized, and his monograph, *De La poesía heróico-popular castellana* (1873) revealed him to foreign scholars as a master of scientific method.

MILAZZO, a seaport on the north coast of Sicily, in the province of Messina, 22 m. W. of Messina by rail. Pop. (1901), 16,422. It is mainly built on the low isthmus of a peninsula, which stretches some 3 m. farther north and forms a good harbour: but the old town, which contains a castle, mainly the work of Charles V., lies on a hill above. Milazzo is the ancient *Mylae*, an outpost of Zancle, occupied before 648 B.C., perhaps as early as 716 B.C. (E. A. Freeman, *History of Sicily*, I., pp. 395, 587). It was taken by the Athenians in 426 B.C. The people of Rhegium planted here the exiles from Naxos and Catana in 395 B.C. as a counterpoise to Dionysius' foundation of Tyndaris; but Dionysius soon took it. In the bay Duilius won the first Roman naval victory over the Carthaginians (260 B.C.).

MILDENHALL, a market town in the Stowmarket parliamentary division of Suffolk, England, 76½ m. N.N.E. from London by a branch of the Great Eastern railway from Cambridge. Pop. (1901), 3567. It lies on the edge of Mildenhall Fen, the great Fen district stretching northward and westward from here. The church of St Andrew has an Early English chancel with fine east window and chancel arch. The remainder is principally Perpendicular with a magnificent carved oak roof, ornate north porch and lofty tower with fan tracery within. There is a wooden market cross of the 15th century; the manor house is a picturesque gabled building of the 17th century, and there is a modern public hall. Flour milling is an industry. The discovery of Roman remains indicates a small settlement.

MILDEW (O. Eng. *meledēaw* or *mildeaw*, explained as "mealdew," cf. Ger. *Mehlthau*, with more probability, as "honeydew," Goth. *melith*, honey, cf. Lat. *mel*, Gr. μέλι), a popular name given to various minute fungi from their appearance, and from the sudden, dew-like manner of their occurrence. Like many other popular names of plants, it is used to denote different species which possess very small botanical affinity. The term is applied, not only to species belonging to various systematic groups, but also to such as follow different modes of life. The corn-mildew, the hop-mildew and the vine-mildew are, for example, parasitic upon living plants, and the mildews of damp linen and of paper are saprophytes (Gr. σαπρός, rotten), that is, they subsist on matter which is already dead. As regards mildews in general, the conditions of life and growth are mainly suitable nutrition and dampness accompanied by a high temperature. The life history of the same species of mildew frequently covers two or more generations, and these are often passed on hosts of different kinds. In some cases again the same generation confines its attack to the same kind of host, while in others the same generation grows on various hosts (see FUNGI; HOP; and WHEAT).

MILES, NELSON APPLETON (1839–), American soldier, was born in Westminster, Massachusetts, on the 8th of August 1839. He was engaged in mercantile pursuits in Boston when the Civil War began, and he entered the army in September 1861 as a lieutenant in the 22nd Massachusetts volunteer infantry. He served with distinction in the Peninsular campaign, and at Antietam, Fredericksburg and Chancellorsville, where he received a wound which incapacitated him up to the opening of Grant's Virginia campaign of 1864. He had been commissioned in September 1862 colonel of the 61st New York volunteers, commanded a brigade at the Wilderness and Spottsylvania, and in May 1864 was rewarded for his gallant leadership by the grade of brigadier-general of volunteers. He fought in the Cold Harbor and Petersburg operations in 1864–65, was brevetted major-general of volunteers for his conduct at Reams Station, and at the close of the war was in temporary command of an army corps. In July 1866 he was made colonel of a regular infantry regiment, and in 1867 he was brevetted brigadier-general in the regular army for his services at Chancellorsville and major-general for his services at Spottsylvania. He was promoted to be brigadier-general U.S.A. (Dec. 1880), and to be major-general (April 1890), and in 1895 succeeded General John McA. Schofield as commanding general of the United States army. He was conspicuously successful (1869–1886) in dealing with Indian outbreaks, fighting the Cheyenne, Kiowa and Comanche on Llano Estacado (1875) and the Sioux in Montana (1876), capturing the Nez Percés under Chief Joseph (1877), and defeating the Chiricahua Apaches under Geronimo (1886), and he commanded the United States troops sent to Chicago during the railway riots in 1894. He was in nominal direction of military operations during the war with Spain in 1898, though his personal share of the operations was confined to directing the almost unopposed Porto Rico expedition. He was raised to the rank of lieutenant-general in June 1900, and retired from active service in August 1903. In 1905–1906 he was adjutant-general and chief-of-staff under Governor William L. Douglas in Massachusetts. He wrote *Personal Recollections* (1896), *Military Europe* (1898) and *Observations Abroad* (1899).

MILETUS (mod. *Palatia*), an ancient city of Asia Minor, on the southern shore of the Latmic Gulf near the mouth of the Maeander. Before the Ionic migration it was inhabited by Carians (*Iliad* ii. 876; Herod. i. 146), and pottery, found by Th. Wiegand on the spot proves that the site was inhabited, and had relations with the Aegean world, in the latest Minoan age. The Greek settlers from Pylos under Neleus are said to have massacred all the men in the old city, and built for themselves a new one on the coast. Miletus occupied a very favourable situation at the mouth of the rich valley of the Maeander, and was the natural outlet for the trade of southern Phrygia (Hipponax, *Fr.* 45). It had four harbours, one of considerable size, and its power extended inland for some distance up the valley of the Maeander, and along the coast to the south, where it founded the city of Iasus. Its enterprise extended to Egypt, where it had much to do with the settlement of Naucratis (*q.v.*). Very little "Naucratiti" pottery, however, was found on the site by Wiegand, and only in the Athena temple. The Black Sea trade, however, was the greatest source of wealth to the Ionian cities. Miletus, like the rest, turned its attention chiefly to the north, and succeeded in almost monopolizing the traffic. Along the Hellespont, the Propontis and the Black Sea coasts it founded more than sixty cities—among them Abydus, Cyzicus, Sinope, Dioscurias, Panticapaeum and Olbia. All these cities were founded before the middle of the 7th century; and before 500 B.C. Miletus was decidedly the greatest Greek city. During the time when the enterprise of the seafaring population raised Miletus to such power and wealth nothing is known of its internal history, though the analogy of all Greek cities, and some casual statements in later writers, suggest that the usual struggles took place between oligarchy and democracy, and that tyrants sometimes raised themselves to supreme power. Miletus was equally distinguished at this early time as a seat of literature. The Ionian epic and lyric poetry indeed had its home farther north; philosophy and history were more akin to the practical race of Miletus, and Thales, Anaximander, Anaximenes and Hecataeus all belonged to this city. The poet Timotheus and the famous Aspasia were also natives. The three Ionian cities of Caria—Miletus, Myus and Priene—spoke a peculiar dialect of Ionic.

The Mermnad kings of Lydia found in Miletus their strongest adversary. War was carried on for many years, till Alyattes III. concluded a peace with Thrasybulus, tyrant of Miletus; the Milesians afterwards seem to have acknowledged peaceably the rule of Croesus. On the Persian conquest Miletus passed under a new master; it headed the Ionian revolt of 500 B.C., and was taken by storm after the battle of Lade (see Ionia). Darius massacred most of the inhabitants, transported the rest to Ampe at the mouth of the Tigris, and gave up the city to the Carians. This disaster was long remembered in Greece and made the theme of a tragedy by Phrynichus. Henceforth the history of Miletus has no special interest. It revived indeed when the Persians were expelled from the coast in 479 B.C., became a member of the Delian League (*q.v.*), revolted to Sparta in 412, passed into Carian hands, and opposed Alexander on his southward march, succumbing only to a siege in form (334 B.C.). It was a town of commercial importance throughout the Graeco-Roman period, and received special attention from Trajan. Its harbours, once protected by Lade and the other Tragasaean islands, were gradually silted up by the Maeander, and Lade is now a hill some miles from the coast. Ephesus took its place as the great Ionian harbour in Hellenistic and Roman times. Miletus became the seat of a Christian bishopric and was strengthened by a Byzantine castle (*κάστρον τῶν Παλατίων*) built above the theatre; but its decay was inevitable, and its site is now a marsh.

Since 1899 Miletus has been the scene of extensive excavations directed by Dr Th. Wiegand for the Berlin Academy. The ruins lie about the base of a hillock projecting north-east into a bend of the Maeander. On the north is a well-preserved theatre of Roman times on the site of an older Greek building. When complete it had 54 rows of seats. It was as large as any theatre in Asia Minor, and is still imposing, the auditorium, though deprived of its upper ranks and colonnade, rising nearly 100 ft. Cyriac of Ancona described the building as practically complete in his day (1446). The front is over 150 yds. long. East of this was the ancient north harbour, now silted up, and on the hillside above it stood a large heroön of Hellenistic time remarkable for being, like the tomb of Brasidas at Amphipolis, within the walls. South of the harbour head lies the Hellenistic agora with ruins of large magazines of Doric style. South of these again lie a nymphaeum of the age of Titus, and a senate-house of theatral form. On the east opens a great hall surrounded by porticoes and enclosing a high altar of Artemis, once richly adorned with reliefs. The Roman agora lies beyond this again. A straight street leads south-west from the north harbour to the Didyma Gate in the wall, which runs across the neck of the peninsula and was rebuilt by Trajan, when he undertook to raise the level of the outer quarters of the city; and streets cross this at right angles in the geometric Hellenistic manner. A Sacred Way lined with tombs, led to Didymi. Two temples have been discovered by Dr Wiegand, one, on the south-east, being a large sanctuary of Apollo Delphinius with triple colonnade enclosing a court with central tripod. This seems to have been the chief temple of the city and the place where public records, treaties, &c., were engraved. The other temple, an archaic sanctuary of Athena, lies west of the stadium.

Wiegand, "Vorläufige Berichte über die Ausgrabungen in Milet," in *Sitzungsberichte* of the Berlin Academy (1900, foll.); A. von Salis, "Die Ausgrabungen in Milet und Didyma" in *Neue Jahrb. f. d. k. Alt.*, xxv. 2, 1910. (D. G. H.)

MILFORD, a township of New Haven county, Connecticut, U.S.A., on Long Island Sound, separated from the township of Stratford on the W. by the Housatonic river, and about 10 m. S.W. of New Haven. Pop. (1890), 3811; (1900), 3783, including 541 foreign-born and 173 negroes; (1910), 4366. Area, about 16 sq. m. Milford is served by the New York, New Haven & Hartford railroad, and by an electric line connecting with Bridgeport and New Haven. Within its borders are various popular beaches, including Woodmont (incorporated as a borough in 1903), Pond Point, Bay View, Fort Trumbull Beach (where a fortification, named Fort Trumbull, was erected in 1776), Myrtle Beach, Meadow's End, Walnut Beach and Milford Point. The township is traversed by the Wepowaug river, which here empties into the Sound. Milford is a typical old New England town, and many of the permanent inhabitants are descendants from the first settlers. The burying-ground includes the tomb of Robert Treat (1622–1710), commander of the Connecticut troops in King Philip's War, leader of the company that founded Newark, New Jersey, governor of Connecticut (from 1683 to 1698) at the time its charter was demanded by Governor Andros in 1686–1687, and deputy-governor in 1676–1683 and 1698–1708; and also that of Jonathan Law (1674–1751), governor of Connecticut from 1742 to 1751. Spanning the Wepowaug river near a gorge and not far from its mouth is a granite bridge and tower, built, as a memorial to the first settlers, in 1889, in connexion with the celebration of the 250th anniversary of the founding of the town. Milford has a beautiful green of about four acres, containing a soldiers' monument. It has also the Taylor Library (founded in 1894), and along the Sound are many summer residences. Named after Milford, England, it was founded in 1639 by Rev. Peter Prudden and his followers from New Haven and Wethersfield. The land was purchased from the Indians for 6 coats, 10 blankets, 1 kettle, 12 hatchets, 12 hoes, 24 knives and 12 small mirrors. A "church-state" was immediately organized after the model of that of New Haven, but two or three years later the town bestowed suffrage on six of its inhabitants who were not church members. These citizens were an obstacle to the town's admission to the New Haven Jurisdiction, which was formed in 1643, but in the following year a compromise was effected and Milford was admitted on condition that, in the future, suffrage should be granted only to church members and that none of the objectionable six should be elected to any office of the Jurisdiction. In 1664 Milford, with the other members of the Jurisdiction, was absorbed by Connecticut; this caused considerable dissatisfaction and some of the inhabitants under the lead of Robert Treat removed to New Jersey and assisted in the founding of Newark. The regicides Whalley and Goffe were concealed in Milford from 1661 to 1664.

See M. Louise Greene, "Early Milford," in the *Connecticut Magazine*, vol. v. (Hartford, 1899).

MILFORD, a township of Worcester county, Massachusetts, U.S.A., about 16 m. S.E. of Worcester. Pop. (1890), 8780; (1900) 11,376, of whom 3342 were foreign-born; (1910 census) 13,055. Within its area of about 15 sq. m. are a large rural population and the village of Milford, on the Charles river, about 33 m. S.W. of Boston, served by the Boston & Albany, the New York, New Haven & Hartford and the Grafton & Upton railways (the last named having its passenger department operated by electricity and its freight by steam, and connecting Milford with North Grafton), and by inter-urban electric lines. The village has a memorial hall, housing the public library, and in the township there is an excellent hospital, the gift of Eben. S. Draper. The village is a shipping point for an agricultural and manufacturing district. In 1905 the value of the township's factory products was $3,390,504 (32·8% more than in 1900). The most important manufactures are boots and shoes; the industry was established in 1795, and for many years the special product was brogans for Southern negroes. In 1908 there were 12 large granite quarries in the township (north and north-east of the village). Milford granite is the typical stone of an area reaching into Rhode Island south of the southern boundary of Providence county; it is a biotite granite of post-Cambrian age, is generally pinkish-gray in colour (owing to the large proportion of feldspar among its constituents), and is widely used for building purposes. The township was the east precinct of Mendon until 1780, when it was incorporated; in 1835 parts of Holliston and Hopkinton were annexed; in 1886 a part was separated as Hopedale.

See Adin Ballou, *History of Milford* (Boston, 1882); and T. Nelson Dale, *The Chief Commercial Granites of Massachusetts, New Hampshire and Rhode Island* (Washington, 1908), Bulletin 354 of the U.S. Geological Survey.

MILFORD HAVEN, a market town, seaport, urban district and contributory parliamentary borough of Pembrokeshire, Wales, situated on the north shore of the celebrated harbour of the same name. Pop. (1901), 5102, including the adjacent village of Hakin. Milford Haven is the terminus of a branch-line of the South Wales section of the Great Western railway. The town possesses a pier and important dock accommodation, including a graving-dock 600 ft. long, and is the centre of a valuable and increasing fishing industry. The promenade of Hamilton Terrace commands a fine view of the broad expanse of the Haven with its various towns and forts.

The present town of Milford Haven, originally a hamlet in the parish of Steynton, is of modern growth, and was first called into existence by the exertions of the Hon. R. F. Greville, nephew of Sir William Hamilton, who in 1790 laid out a town on this spot, the advantages of which as a convenient port for the Irish traffic he clearly recognized. In the opening years of the 19th century a royal dockyard was established here, but in 1814 dockyard and arsenal were removed to Paterchurch near Pembroke. The growth of the town was further checked twenty years later by the development of Neyland, or New Milford, further east on the Haven, whither the Irish packet service was transferred; but towards the close of the 19th century the town recovered much of its former prosperity. The importance of the place is wholly due to its excellent situation on the splendid land-locked harbour, which is here 2 m. broad.

Milford Haven itself, designated by the Welsh Aberdaugleddau, as the estuary of the united East and West Cleddy rivers, has played an important part on several occasions in the course of history. Throughout Plantagenet times it formed the chief point of embarcation for Ireland. It was from Milford Haven that Henry II. set sail for the conquest of Ireland in 1172, and to this harbour he made his return journey. In 1399 Richard II. landed at Milford Haven from Ireland, shortly before his surrender to Henry of Lancaster, afterwards Henry IV., in whose reign a French fleet with 12,000 men on board sailed to the Haven and disembarked with the object of assisting the rebellion of Owen Glendower. In 1485 Henry, earl of Richmond, disembarked here on his return from France, and was welcomed on landing by Sir Rhys ap Thomas and much of the chivalry of Wales. In 1588 the leading persons of Pembrokeshire, with Bishop Anthony Rudd of St David's at their head, petitioned Queen Elizabeth to fortify the Haven against the projected Spanish invasion, upon which the block-houses of Dale and Nangle at either side of the mouth of the harbour were accordingly erected. During the 19th century numerous forts have been constructed for the protection of the Haven and of the royal dockyard at Pembroke Dock.

MILICZ, or MILITSCH (d. 1374), Bohemian divine, was the most influential among those preachers and writers in Moravia and Bohemia who, during the 14th century, in a certain sense paved the way for the reforming activity of Huss. The date of his birth is not known, but he was in holy orders in 1350, in 1360 was attached to the court of the emperor Charles IV., whom he accompanied into Germany in that year, and about the same time also held a canonry in the cathedral of Prague along with the dignity of archdeacon. About 1363 he resigned all his appointments that he might become a preacher pure and simple; he addressed scholars in Latin, and (an innovation) the laity in their native Czech, or in German, which he learnt for the purpose. He was conspicuous for his apostolic poverty and soon roused the enmity of the mendicant friars. The success of his labours made itself apparent in the way in which he transformed the notorious "Benatki" street of Prague into a benevolent institution, "Jerusalem." As he viewed the evils inside and outside the church in the light of Scripture, the conviction grew in his mind that the "abomination of desolation" was now seen in the temple of God, and that antichrist had come, and in 1367 he went to Rome (where Urban V. was expected from Avignon) to expound these views. He affixed to the gate of St Peter's a placard announcing his sermon, but before he could deliver it was thrown into prison by the Inquisition. Urban, however, on his arrival, ordered his release, whereupon he returned to Prague, and from 1369 to 1372 preached daily in the Teyn Church there. In the latter year the clergy of the diocese complained of him in twelve articles to the papal court at Avignon, whither he was summoned in Lent 1374, and where he died in the same year, not long after being declared innocent and authorized to preach before the assembly of cardinals. He was the author of a *Libellus de Antichristo*, written in prison at Rome, a series of *Postillae* and *Lectiones quadragesimales* in Latin, and a similar series of *Postils* (devotional tracts) in Czech.

See Count Lützow, *Life and Times of Master John Hus* (1909), pp. 27-38.

MILITARY FRONTIER (Ger. *Militärgrenze*, Slav. *Granitza*), a narrow strip of Austrian-Hungarian territory stretching along the borders of Turkey, which had for centuries a peculiar military organization, and from 1849 to 1873 constituted a crown-land. As a separate division of the monarchy it owed its existence to the necessity of maintaining during the 16th and 17th centuries a strong line of defence against the invasions of the Turks, and may be said to have had its origin with the establishment of the captaincy of Zengg (a coast town about 35 m. south-east of Fiume) by Matthias Corvinus and the introduction of Uskoks (*q.v.*) into Croatia. By the close of the 17th century there were three frontier "generalates"—Carlstadt, Warasdin and Petrinia or Petrinja (the last also called the Banal). After the defeat of the Turkish power by Prince Eugene it was proposed to abolish the military constitution of the frontier, but the change was successfully resisted by the inhabitants of the district; in fact a new Slavonian frontier district was established in 1702, and Maria Theresa extended the organization to the march-lands of Transylvania (the Szekler frontier in 1764, the Wallachian in 1766).[1]

As a reward for the service it rendered the government in the suppression of the Hungarian insurrection in 1848, the Military Frontier was erected in 1849 into a crown-land, with a total area of 15,182 sq. m. and a population of 1,220,503. In 1851 the Transylvanian portion (1177 sq. m.) was incorporated with the rest of Transylvania; and in 1871 effect was given to the imperial decree of 1869 by which the districts of the Warasdin regiments (St George and the Cross) and the towns of Zengg, Belovar, Ivanič, &c., were "provincialized" or incorporated with the Croatian-Slavonian crown-land. In 1872 the Banat regiments followed suit; and in 1873 the old military organization was abolished in the rest of the frontier. Not till 1881, however, were the Croatian-Slavonian march-lands completely merged in the kingdoms to which they naturally belonged.

The social aspect of the military frontier régime is interesting. The *zadruga* system of land tenure was artificially kept in existence (see SERVIA). Watch-towers with wooden clappers and the beacons which flashed the alarm along the whole frontier in a few hours are still features in the landscape.

MILITARY LAW, "the law which governs the soldier in peace and in war, at home and abroad. At all times and in all places the conduct of officers and soldiers as such is regulated by military law." The above is the definition as given in the opening chapter of the *Manual of Military Law*, which is issued under the authority of the English War Office, and which is the text-book used by all English courts martial. The definition is, however, somewhat too wide, as the British system does not exclude in time of peace the action of the civil courts. In time of peace all persons who belong to the military class in most European continental countries are judged by military law and by military courts. There is also in most continental countries an intermediate stage between war and peace, known as in *état de siège*, which may be declared for a fixed period for a district, or even a city, by reason of domestic insurrection or the presence of an enemy. It requires legislative enactment. Thirdly comes a state of war, when the military authorities are supreme; and whilst they can call upon the civil power to act in concert with them, the military authority is final. This is a brief summary of the system of military law that prevails in most countries of the continent. The cardinal point of difference between the British and the continental systems lies in the fact that in the United Kingdom the soldier is not only a soldier, but a citizen also; and although he may be tried for civil offences by a military tribunal, the power is not exercised in all cases. Thus treason, treason-felony, murder, manslaughter, rape, are brought before a civil court in times of peace, if the offence is committed in the United Kingdom, or if it is committed anywhere else in the king's dominions, except Gibraltar, within a hundred miles from a place where the offender can be tried by a civil court. Minor civil offences, when not committed within military lines, or when the person affected by the offence is a civilian, or when it is a case for a jury, or where intricate questions of law may arise, may also be brought before a civil tribunal. But an offence, of whatever nature, committed on active service would be brought before a military tribunal.

English Law.

The military law of England in early times existed, like the forces to which it applied, in a period of war only. Troops were raised for a particular service, and were disbanded upon the cessation of hostilities. The crown, of its mere prerogative, made laws known as Articles of War, for the government and discipline of the troops while thus embodied and serving. Except for the punishment of desertion, which offence was made a felony by statute in the reign of Henry VI., these ordinances or Articles of War remained almost the sole authority for the enforcement of discipline until 1689, when the first Mutiny Act was passed and the military forces of the crown were brought under the direct control of parliament. Even the Parliamentary forces in the time of Charles I. and Cromwell were governed, not by an act of the legislature, but by articles of war similar to those issued by the king and authorized by an ordinance of the Lords and Commons, exercising in that respect the sovereign prerogative. This power of law-making by prerogative was, however, held to be applicable during a state of actual war only, and attempts to exercise it in time of peace were ineffectual. Subject to this limitation it existed for considerably more than a century after the passing of the first Mutiny Act. From 1689 to 1803, although in peace time the Mutiny Act was occasionally suffered to expire, a statutory power was given to the crown to make Articles of War to operate in the colonies and elsewhere beyond the seas in the same manner as those made by prerogative operated in time of war. In 1715, in consequence of the rebellion, this power was created in respect of the forces in the kingdom. But these enactments were apart from and in no respect affected the principle acknowledged all this time—that the crown of its mere prerogative could make laws for the government of the army in foreign countries in time of war. The Mutiny Act of 1803 effected a great constitutional change in this respect: the power of the crown to make any Articles of War became altogether statutory, and the prerogative merged in the act of parliament. So matters remained till the year 1879, when the last Mutiny Act was passed and the last Articles of War were promulgated. The Mutiny Act legislated for offences in respect of which death or penal servitude could be awarded, and the Articles of War, while repeating those provisions of the act, constituted the direct authority for dealing with offences for which imprisonment was the maximum punishment as well as with many matters relating to trial and procedure. The act and the articles were found not to harmonize in all respects. Their general arrangement was faulty, and their language sometimes obscure. In 1869 a royal commission recommended that both should be recast in a simple and intelligible shape. In 1878 a committee of the House of Commons endorsed this view and made certain recommendations as to the way in which the task should be performed. In 1879 the government submitted to parliament and passed into law a measure consolidating in one act both the Mutiny Act and the Articles of War, and amending their provisions in certain important respects. This measure was called the "Army Discipline and Regulation Act 1879." After one or two years' experience of its working it also was found capable of improvement, and was in its turn superseded by the Army Act 1881, which now forms the foundation and the main portion of the military law of England. It contains a proviso saving the right of the crown to make Articles of War, but in such a manner as to render the power in effect a nullity; for it enacts that no crime made punishable by the act shall be otherwise punishable by such articles. As the punishment of every conceivable offence is provided for by the act, any articles made thereunder can be no more than an empty formality having no practical effect. Thus the history of English military law up to 1879 may be divided into three periods, each having a distinct constitutional aspect: (1) that prior to 1689, when the army, being regarded as so many personal retainers of the sovereign rather than servants of the state, was mainly governed by the will of the sovereign; (2) that between 1689 and 1803, when the army, being recognized as a permanent force, was governed within the realm by statute and without it by the prerogative of the crown; and (3) that from 1803 to 1879, when it was governed either directly by statute or by the sovereign under an authority derived from and defined and limited by statute. Although in 1879 the power of making Articles of War became in effect altogether inoperative, the sovereign was empowered to make rules of procedure, having the force of law, which regulate the administration of the act in many matters formerly dealt with by the Articles of War. These rules, however, must not be inconsistent with the provisions of the Army Act itself, and must be laid before parliament immediately after they are made. Thus in 1879 the government and discipline of the army became for the first time completely subject either to the direct action or the close supervision of parliament.

---

[1] By 1848 the following had come to be the division of the Military Frontier: (1) *The Carlstadt* (*Carlowatz*), *Warasdin and Banal Generalate*; corresponding to the original three generalates. (2) *The Slavonian Generalate*; (district of Mitrovica). (3) *The Banat Generalate*; south and east of Temesvar, and (4) *The Transylvanian Generalate.* Twelve towns, known as "military communities," had communal constitutions not unlike those of the free towns of Hungary-Carlopago, Zengg, Petrinia, Kostajnica, Belovar, Ivanič, Brod, Peterwardein, Carlowitz, Semlin, Pancsova and Weisskirchen.

A further notable change took place at the same time. The Mutiny Act had been brought into force on each occasion for one year only, in compliance with the constitutional theory that the maintenance of a standing army in time of peace, unless with the consent of parliament, is against law. Each session therefore the text of the act had to be passed through both Houses clause by clause and line by line. The Army Act, on the other hand, is a fixed permanent code. But constitutional traditions are fully respected by the insertion in it of a section providing that it shall come into force only by virtue of an annual act of parliament. This annual act recites the illegality of a standing army in time of peace unless with the consent of parliament, and the necessity nevertheless of maintaining a certain number of land forces (exclusive of those serving in India) and a body of royal marine forces on shore, and of keeping them in exact discipline, and it brings into force the Army Act for one year.

Military law is thus chiefly to be found in the Army Act and the rules of procedure made thereunder, the Militia Acts, the Reserve Forces Acts and the Volunteer Acts, together with certain acts relating to the yeomanry, the Territorial and Reserve Forces Act 1907, and various royal warrants and regulations. In the Army (Annual) Act 1906 important amendments were made to the Army Act for the purpose of preventing soldiers convicted of offences against discipline under the act, and not discharged with ignominy, being subjected to the stigma attaching to imprisonment. This was effected by creating a new punishment, termed detention, the places in which soldiers undergo detention being termed detention barracks. The change, while principally one of nomenclature, removed an undoubted grievance. The Army Act itself is, however, the chief authority. Although the complaint has been sometimes made, and not without a certain amount of reason, that it does not accomplish much that it might in point of brevity, simplicity and clearness of expression, it is a very comprehensive piece of legislation, and shows some distinct improvements upon the old Mutiny Acts and Articles of War.

When a person subject to military law commits an offence he is taken into military custody, which means either arrest in his own quarters or confinement. He must without unnecessary delay be brought before his commanding officer, who upon investigating the case may dismiss the charge, if in his discretion he thinks it ought not to be proceeded with, or may take steps to bring the offender before a court martial. Where the offender is not an officer he may dispose of the case summarily, the limit of his power in this respect being seven days' imprisonment with hard labour, a fine not exceeding 10s. for drunkenness, certain deductions from pay, confinement to barracks for twenty-eight days, this involving severe extra drills, deprivations and other minor punishments. Where the offence is absence without leave for a period exceeding seven days, the commanding officer may award a day's imprisonment in respect of each day of such absence up to twenty-one. It is only in the case of the imprisonment exceeding seven days that the evidence before the commanding officer is taken on oath, and then only in the event of the accused so desiring it. The commanding officer is enjoined by regulation not to punish summarily the more serious kind of offences, but his legal jurisdiction in this respect is without limit as regards any soldier brought before him, and when he has dealt summarily with a case the accused is free from any other liability in respect of the offence thus disposed of. In any instance where the commanding officer has summarily awarded imprisonment, fine or deduction from pay, the accused may claim a district court martial instead of submitting to the award.

Ordinary courts martial are of three kinds, viz. (1) a regimental court martial, usually convened and confirmed by the commanding officer of the regiment or detachment, presided over by an officer not under the rank of captain, composed of at least three officers of the regiment or detachment with not less than one year's service, and having a maximum power of punishment of forty-two days' detention; (2) a district court martial, usually convened by a general officer having authority to do so, consisting of not less than three officers, each with not less than two years' service, and having a maximum power of punishment of two years' imprisonment; (3) a general court martial, the only tribunal having authority to try a commissioned officer, and with a power of punishment extending to death or penal servitude, for offences for which these penalties are authorized by statute; it consists of not less than nine officers in the United Kingdom, India, Malta and Gibraltar and of five elsewhere, each of whom must have had over three years' service, five being not under the rank of captain. There is another kind of tribunal, viz. a field general court martial. It is convened (1) by any officer in command of a detachment or portion of troops beyond the seas when not on active service, or by any officer in immediate command of a body of forces on active service where it appears to him on complaint or otherwise that a person subject to military law has committed an offence. The officer must be satisfied that it is not practicable, with due regard to the public service, to try the person by an ordinary court martial. The quorum of the court is three, if consistent with military exigencies, and each member must have held a commission for not less than a year. The quorum may be reduced when the public service requires it. The procedure of ordinary courts martial is observed as far as possible, and the proceedings always should be in writing when possible. But in the circumstances in which these courts are assembled, it is not always possible to adhere to the technical rules which obtain in the ordinary tribunals, although the broad principles are not violated. The evidence on a field general court martial is taken on oath. The prisoner may cross-examine the witnesses for the prosecution, and may call any available witnesses for his defence. The prisoner is allowed to address the court in his own defence.

The Army Act prescribes the maximum punishment which may be inflicted in respect of each offence. That of death is incurred by various acts of treachery or cowardice before the enemy, or by, when on active service, interfering with or impeding authority, leaving without orders a guard or post, or when sentry sleeping or being drunk on a post, plundering or committing an offence against the person or property of an inhabitant, intentionally causing false alarms, or deserting. Whether upon active service or not, a soldier also becomes liable to the punishment of death who mutinies or incites to or joins in or connives at a mutiny, who uses or offers violence to or defiantly disobeys the lawful command of his superior officer when in the execution of his office. Penal servitude is the maximum punishment for various acts and irregularities upon active service not distinctly of a treacherous or wilfully injurious character, for using or offering violence or insubordinate language to a superior, or disobeying a lawful command when upon active service. The same punishment is applicable when not upon active service to a second offence of desertion or fraudulent enlistment (*i.e.* enlistment by one who already belongs to the service), certain embezzlements of public property, wilfully releasing without authority a prisoner or wilfully permitting a prisoner to escape, enlisting when previously discharged from the service with disgrace without disclosing the circumstances of such discharge, or any other offence which by the ordinary criminal law of England is punishable with penal servitude. Imprisonment for two years is the maximum punishment for minor forms and degrees of those offences which if committed upon active service would involve death or penal servitude, such as using or offering violence or insubordinate language to a superior or disobeying a lawful command, and for the following offences: resisting an escort, breaking out of barracks, neglect of orders, a first offence of desertion or attempted desertion or aiding or conniving at desertion, or of fraudulent enlistment, absence without leave, failure to appear at parade, going beyond prescribed bounds, absence from school, malingering or producing disease or infirmity, maiming with intent to render a soldier unfit for service, an act of a fraudulent nature, disgraceful conduct of a cruel, indecent or unnatural kind, drunkenness, releasing a prisoner without proper authority or allowing him to escape, being concerned in the unreasonable detention of a person awaiting trial, escaping or attempting to escape from lawful custody, conniving at exorbitant exactions, making away with, losing by neglect, or wilfully injuring military clothing or equipments, ill-treating a horse used in the service, making false or fraudulent representations in public documents, making a wilfully false accusation against an officer or soldier, making a false confession of desertion or fraudulent enlistment, or a false statement in respect of the prolongation of furlough, misconduct as a witness before a court martial or contempt of such court, giving false evidence on oath, any offence specified in relation to billeting or the impressment of carriages, making a false answer to a question put upon attestation, being concerned in unlawful enlistment, using traitorous or disloyal words regarding the sovereign, disclosing any circumstance relating to the numbers, position, movements or other circumstances of any part of His Majesty's forces so as to produce effects injurious to His Majesty's service, fighting or being concerned in or conniving at a duel, attempting suicide, obstructing the civil authorities in the apprehension of any officer or soldier accused of an offence, any conduct, disorder or neglect to the prejudice of good order and military discipline, any offence which if committed in England would be punishable by the law of England. There is another offence which can be committed by officers only, namely "scandalous conduct unbecoming the character of an officer and a gentleman." It necessitates cashiering, a punishment which in the case of an officer may be awarded as an alternative to imprisonment in several other instances. There is also an offence peculiar to officers and non-commissioned officers, that of striking or ill-treating a soldier or unlawfully detaining his pay. A sentence of cashiering as distinguished from that of dismissal in the case of an officer involves an incapacity to serve the crown again. An officer may be also sentenced to forfeiture of seniority of rank and to reprimand or severe reprimand. A non-commissioned officer may be sentenced to be reduced to a lower grade or to the ranks, and where sentenced to penal servitude or imprisonment the tribunal also has power to deprive him of his seniority. The Army Council in England, or the commander-in-chief in India or in either of the presidencies, may also cause a non-commissioned officer to be reduced to a lower grade or to the ranks. An acting non-commissioned officer may be ordered by his commanding officer for an offence or for inefficiency or otherwise to revert to his permanent grade—in other words, to forfeit his acting rank.

It will have been observed that persons subject to military law are liable to be tried by court martial for offences which if committed in England would be punishable by the ordinary law, and to suffer either the punishment prescribed by the ordinary criminal law or that authorized for soldiers who commit offences to the prejudice of good order and military discipline. The effect of the latter alternative is that for many minor offences for which a civilian is liable to a short term of imprisonment, or perhaps only to a fine, a soldier may be awarded two years' imprisonment or detention. A court martial, however, cannot take cognizance of the crimes of treason, murder, manslaughter, treason-felony or rape if committed in the United Kingdom. If one of these offences be committed in any place within His Majesty's dominions other than the United Kingdom or Gibraltar, a court martial can deal with it only if it be committed on active service or in a place more than 100 miles from a civil court having jurisdiction to try the offence. With regard to all civil offences the military law, it is to be understood, is subordinate to the ordinary law, and a civilian aggrieved by a soldier in respect of a criminal offence against his property or person does not forfeit his right to prosecute the soldier as if he were a civilian.

The crimes for which soldiers are most usually tried are desertion, absence without leave, loss of necessaries, violence or insubordination to superiors, drunkenness, and various forms of conduct to the prejudice of discipline. The punishments are, generally speaking, gauged as much with regard to the character and antecedents of the prisoner as to the particular offence. For a first offence of an ordinary kind a district court martial would give as a rule fifty-six days' imprisonment with hard labour, for a second or graver crime eighty-four days. There are not many instances in which the period of imprisonment exceeds six months. Corporal punishment, which had been practically limited to offences committed upon active service, and in 1879 to crimes punishable with death, was finally abolished in 1881, and a summary punishment substituted. The practice of marking a soldier with the letters "D" (deserter) or "BC" (bad character), in order to prevent his re-enlistment, was abolished in 1879 in deference to public opinion, which erroneously adopted the idea that the "marking" was effected by red-hot irons or in some other manner involving torture. Many military men regretted its abolition, and maintained that if the practice were still in force the army would not be tainted by the presence of many bad characters who find means of eluding the vigilance of the authorities and enlisting after previous discharge.

The course of procedure in military trials is as follows. When a soldier is remanded by his commanding officer for trial by a district or general court martial, a copy of the charge, together with the statements of the witnesses for the prosecution (called the summary of evidence), is furnished to him, and he is given proper opportunity of preparing his defence, of communicating with his witnesses or legal adviser, and of procuring the attendance of his witnesses. Further, if he desires it, a list of the officers appointed to form the court shall be given him. Any officer is disqualified to sit as a member who has convened the court, who is the prosecutor or a witness for the prosecution, who has made the preliminary inquiry into the facts, who is the prisoner's commanding officer, or who has a personal interest in the case. The prisoner may also object to any officer on the ground of bias or prejudice, similarly as a civilian might challenge a juror. Except as regards the delay caused by the writing out of the evidence, the procedure at a court martial is very much the same as that at an ordinary criminal trial—the examination and cross-examination of the witnesses, addresses of the prosecutor and prisoner, and the rules governing the admission or rejection of evidence being nearly identical. At a general court martial, and sometimes at a district court, a judge advocate representing the judge advocate general officiates, his functions being very much those of a legal assessor to the court. He advises upon all points of law, and sums up the evidence just as a judge charges a jury. When the prisoner pleads guilty the court finds a verdict accordingly, reads the summary of evidence, hears any statement in mitigation of punishment, and takes evidence as to character before proceeding to pass sentence. The sentence is that of the majority of the court, except where death is awarded, when two-thirds of the members in the case of a general court martial and the whole in that of a field general court martial must concur. When an acquittal upon all the charges takes place the verdict is announced in open court, and the prisoner is released without any further proceeding. When the finding is "guilty," evidence as to character is taken, and the court deliberates in private upon the sentence, but the result is not made known until the proceedings are confirmed and promulgated. No conviction or sentence has any effect until it is thus confirmed by the proper authority. The confirming authority in the case of a regimental court is the commanding officer, in that of a district court martial an officer authorized to convene general courts martial or some officers deriving authority to confirm the findings and sentences of district courts martial, and in that of a general court, if held in the United Kingdom, His Majesty, and if abroad in most cases the general officer commanding. The confirming authority may order the reassembling of the court in order that any question or irregularity may be revised and corrected, but not for the purpose of increasing a sentence. He may, however, of his own discretion and without further reference to the court, refuse confirmation to the whole or any portion of the finding or sentence, and he may mitigate, commute or entirely remit the punishment. In the case of a general court martial the proceedings are sent to the judge advocate general, who submits to the sovereign his opinion as to the legality of the trial and sentence. If they are legal in all respects he sends the proceedings to the Army Council, upon whom rests the duty of advising the sovereign regarding the exercise of clemency. In addition to confirmation, however, every general or district court martial held out of India has another ordeal to go through. It is reviewed and examined in the office of the judge advocate general, and any illegality that may be disclosed is corrected and the prisoner is relieved of the consequences. To a certain extent a protection against illegality also exists in the case of regimental courts martial. A monthly return of those held in each regiment is laid before the general commanding, by whom any question that might appear to him doubtful would be referred to the adjutant general or the judge advocate general for decision. It is to be noted, however, that the judge advocate general, although fulfilling duties which are in their nature judicial, is only an adviser. He is not actually a judge in an executive sense, and has no authority directly to interfere with or correct an illegal conviction. In many cases the law thus provides no remedy for an officer or soldier who may have been wronged by the finding or sentence of a court martial—for instance, through a verdict not justified by the evidence or through a non-observance of the rules and practice prescribed for these tribunals. A person who has suffered injustice may appeal to the king's bench division of the high court of justice. But, speaking generally, that tribunal would not interfere with a court martial exercising its jurisdiction within the law as regards the prisoner, the crime and the sentence. In most cases, therefore, the virtual protector of an accused person against illegality is the judge advocate general, who personally advises the sovereign and the military authorities that the law shall be complied with (see JUDGE ADVOCATE GENERAL).

The Army Act applies to European officers and soldiers serving in India in the same manner as to the rest of the army, but natives of India are governed by their own Articles of War, and in the case of civil offences they are dealt with according to the provisions of the Indian penal code. There are judge advocates general for each of the presidencies, and a deputy judge advocate at each of the more important military centres.

Important changes were made in the system of courts of inquiry by an Army Order of the 10th of February 1902. A court of inquiry is and has been an assembly of officers directed by a commanding officer to collect evidence and report with respect to a transaction into which he cannot conveniently

Courts of Inquiry.

himself make inquiry. But now, whenever any inquiry affects the character or military reputation of an officer or soldier, full opportunity must be given him of being present at the inquiry and of giving any evidence or making any statement, or cross-examining adverse witnesses, or producing witnesses, on his own behalf. Evidence may now be ordered to be taken on oath if the assembling officer thinks the case requires it. No proceedings of a court of inquiry, no confession, statement or answer, is admissible in a court martial. But an officer or soldier tried by court martial in respect of matter which has been the subject of a court of inquiry is entitled to a copy of the proceedings on payment of the cost of the copy. The finding and sentence are only valid after confirmation by the proper military authority. A sentence of death or penal servitude can only be confirmed by the general or field officer in command of the forces with which the prisoner is present. The rule which allows the prisoner and his wife to tender their evidence on oath under the Criminal Evidence Act 1898 as regards evidence is applicable to field general courts martial. It is useful to note that the Army Act, sec. 70, enables His Majesty to make new provisions under the hand of a secretary of state for, amongst other things, the assembly and the procedure of courts of inquiry. The power to make changes by Army Order or rule is only limited by the principle that the rules must not be contrary to or inconsistent with the act.

Continental Military Law.

In an authoritative report published by the Norwegian government, and compiled by a trained Norwegian lawyer who visited the various countries, the systems of twenty-two states are reviewed. The earliest military law still in force is found in Norway and Denmark, and dates from 1683, while England and Sweden date from 1881. Sweden has a military penal code, and England is ruled by the Army Act. There are two kinds of military courts of first instance: (1) those belonging to separate military bodies, such as divisions, brigades, regiments; (2) those having jurisdiction in a certain territory, and their seat determined. In times of war the courts must follow the military bodies. In Bavaria and Switzerland a military jury is attached to a court martial. In several states "auditors," *i.e.* judicial guides, are attached to courts martial. In some a military jurisconsult (lawyer) is attached as judge, always a fixed post. This obtains in Sweden, Finland, Austria-Hungary, Switzerland and Portugal. In Norway, Denmark, Sweden, Finland, Belgium, Great Britain, Germany, Austria, United States, Spain, Württemberg and Switzerland the presiding officer is chosen for the single trial. In other states the military judges are appointed for a certain term, usually six months. The quorum of judges required on military courts on the continent differs. Seven judges sit in Belgium, Holland, France, Spain, Portugal, Greece, Turkey and Württemberg; three only, in cases of ordinary offences committed by non-commissioned officers and soldiers in Switzerland, Russia, the United Kingdom, United States and Bavaria. In grave cases in the United Kingdom five to nine sit, nine in Russia, five to thirteen in the United States. In Norway and Denmark the court is of thirteen up to twenty-five, unless replaced by a commission and a military lawyer.

Summary Courts Martial.

In Norway, Denmark, Sweden, Finland, and Bavaria and other places in Germany, special summary courts martial are held when necessary. Certain forms and legal guarantees are then dispensed with. Such are held in Belgium and Holland "in a town or place in state of siege." *La Prévôté* is a special court of a judge assisted by a registrar, for vagabonds, servants, sutlers, and with a very limited competence over soldiers who have committed a petty offence, held in time of war in France, Rumania and Greece.

The United Kingdom has a summary court martial when the regular court martial cannot be held without injuring the military service. In the United States there are the "field officers' court martial" and "military commission," consisting of three officers. The second is for judging spies and some other matters that escape the jurisdiction of the regular courts martial. A special military tribunal in Germany judges the officials attached to the army. *Courts of honour* exist in Russia, Germany, Bavaria, Württemberg, Austria-Hungary and Spain. Great Britain and the United States have the system of a "court of inquiry." This was only a commission of inquiry, but it is now public, the accused is present, and the witnesses are sworn.

Competence of Military Courts.

Soldiers not on active service, says the Swedish report, should be answerable for infractions of common law under the jurisdiction of the civil courts. All infractions of military order or discipline committed by soldiers, whether on active service or no, should be judged by military courts. In time of war, it is equally admitted, military courts must judge all offences, even offences at common law, committed by soldiers forming part of an army on campaign. The difference lies in regard to offences committed in time of peace. Sweden, Great Britain, France, Italy and the United States, as a general rule, place offences against the common law (*infractions de droit commun*) *in time of peace* under the jurisdiction of the civil courts. In the United States offences against good order, in Great Britain personal offences (such as drunkenness), are judged by courts martial. In most other states the general rule is that soldiers, even in time of peace, if on actual service are judged by courts martial. In the case of complicity between a soldier and a civilian, sometimes one is judged by a military and the other by a civil court (in Germany, Switzerland and Spain), sometimes both by a military court (Belgium, Italy, Servia, Rumania and Greece); sometimes it depends on the nature of the crime—in the United Kingdom, United States, Sweden, Finland, Holland and Portugal. In Norway a mixed tribunal judges them.

Procedure.

The procedure in military courts differs according to the countries. In some systems (*a*) the examination and preparation of evidence are confided to a *juge d'instruction*; (*b*) in other systems they are confided to a special commission of inquiry; (*c*) again, in other places they are left to the court martial itself that will judge the case. The United Kingdom and the United States follow the last plan. There is no preparatory examination in these two countries. A commission of inquiry for the preparation of evidence is held in Norway, Denmark, Germany, Württemberg, Austria-Hungary, Servia, Belgium and Holland. An auditor directs these courts of inquiry. In Russia an officer acts as *juge d'instruction*; in grave cases he must be a military jurisconsult. In Italy, Spain, Rumania, Greece and Turkey an officer acts as *juge d'instruction.*

Publicity.

The proceedings before a court martial are usually public, except in the case of matters that offend morality, compromise public order, or where publicity is considered injurious to the interests of the service (cases of discipline, disclosing plans, &c.). This does not apply (except in Great Britain and the United States) to the proceedings before the courts charged with preliminary investigation. In several states, *i.e.* Norway, Denmark, Holland, Austria, Servia, Germany and Württemberg, the public prosecutor is also the counsel of the accused. The auditor who directs the court of inquiry fills these offices (except in cases of small importance in Germany and Württemberg). In other states there is a special office of public prosecutor. In Spain, Portugal, Rumania, Greece and Turkey he is an officer. In Russia, Belgium, Bavaria, Switzerland and Italy he is a military lawyer. In these countries the accused has the right to choose a counsel, or one is assigned him. In the United Kingdom and the United States, when the matter is grave, the direction of the case is put in the hands of a judge advocate. In the United States the judge advocate is the public prosecutor.

Appeal, when allowed and to whom.

There is no superior tribunal to which to appeal in Denmark, Great Britain and the United States. In Denmark the cases are sent to the auditor-general, who can annul if there is error in form, and send back the case to be tried anew. In Great Britain and the United States judgment in ordinary cases must be confirmed by the commanding officer by whose order the court was called. He can lighten the sentence. In certain cases of great gravity it must go to the head of the state, after passing the revision of the judge advocate general, who in Great Britain is the constitutional adviser of the crown as regards courts martial from the view of legality. There is also in these two countries a special revision of judgments in the judge advocate general's office. This revisional power is the safeguard of military justice, as all decisions are reviewed, and if any illegality is pointed out the proceedings are consequently quashed. The effect of this disapproval is not merely to annul the proceedings, but it also prevents the accruing of any disability or forfeiture. The British judge advocate's office has been much strengthened. It now consists of: (1) The judge advocate general (one of H.M. judges); (2) a deputy judge advocate general, who is a trained lawyer; (3) a deputy judge advocate, also a trained lawyer; (4) a military officer of the rank of colonel who has been called to the bar; (5) in South Africa (since 1899, and on a five-years' appointment from 1902) a colonel who has been called to the bar.

In Germany there is no appeal, except for officials attached to the army. In Austria-Hungary the sentence can be lightened by the commanding officer. It can also be returned for trial by a superior court if it appears to him too light. In Spain all judgments have to be confirmed, and if confirmation is refused, it is carried before the supreme court of the navy and army. The condemned has no power of appeal himself, but all cases of death or life sentences go before the supreme court of the navy and army. Russia only requires the confirmation of the commanding officer. In Rumania and Greece all condemned prisoners in time of peace can demand a court of revision, composed of a general and four superior officers. In time of war the court may be composed of three.

Disciplinary Punishments.

Certain forms of punishment, in all countries but the United States, can be given by the superior officer, without judicial intervention, for small purely military offences, where a summary procedure is required. The offender, if he prefers, may be carried before court-martial. The punishment is immediately carried into force, but the person punished can complain to higher military authority. In that case, if the complaint is not admitted, the punishment is enhanced. The commonest of these disciplinary punishments are deprivation of liberty, confined to barracks, arrests and prison. Certain special punishments obtain in certain countries—for instance, imprisonment in Turkey may be accompanied by a bread-and-water diet; and officers in Finland and Russia may be deprived of advancement.

In 1908 France took steps to abolish courts-martial in time of peace, all common law offences to be judged by the ordinary courts, and breaches of military discipline such as rebellion, insubordination, desertion and the like by mixed courts composed of civil and military magistrates.

See Clode, *Military Forces of the Crown*; T. Gram, *Fonctionnement de la justice militaire dans les différents États de l'Europe.* (JNO. S.)

MILITIA (Fr. *milice*, Ger. *Miliz*, from Lat. *miles*, soldier, *militia*, military service), a term used generally for organized military forces which are not professional in character and not permanently embodied. All ancient armies, with the exception of the personal guards of their leaders, were militias or national levies, remaining under arms for the war or the campaign and returning to their ordinary occupations at the close of each military episode. Militias such as those of the Greek city-states and that of Rome were of course highly trained to the use of arms; so were the barbarian "nations in arms"; which overcame the professionalized Roman armies of the Empire; and although in the Eastern Empire these new fighting elements were absorbed into a fully organized regular arm, in the West the tribal militia system gradually developed into feudalism. The noble and the knight indeed spent the greater part of their lives in the field and devoted themselves from their youth to the cult of arms, but the feudal tenantry, who were bound to give forty days' war service and no more, and the burghers who, somewhat later in the history of civilization, formed the efficient garrisons of the walled towns were true militias. The English Yeomanry indeed almost ruled the battlefield.

In the 15th century the introduction of firearms began to weigh down the balance in favour of the professional soldier. Artillery was always the arm of the specialist. The development of infantry, "fire-power," with the early arquebus and musket, called for the highest skill and steadiness in the individual soldier, and cavalry too adopted the new weapon in the form of long and expensive wheel-lock pistols. In the new military organization there was no place for the unprofessional soldier. The rôle of the unprofessional combatant, generally speaking, was that of an insurgent—harassing small detachments of the enemy, cutting off stragglers, and plundering convoys. Towards the end of the first civil war in England (1645) the country-folk banded themselves together to impose a peace on the two warring armies, but their menace was without effect, and they were easily disarmed by Fairfax and Cromwell, who did not even trouble to hold them as prisoners. The calling out of the *arrière ban* of Franche-Comté in 1675 displayed its ludicrous inefficiency, and thereafter in France, which set the fashion to Europe in all military matters, the "provincial militia," which Louvois and Barbezieux raised in place of the discredited *arrière ban*, was employed partly to find drafts for and partly to augment the regular army.

When a first line army was large enough to absorb the fighting strength of the country there was neither room nor need for a true militia force. This was the case with France under Napoleon's régime, but things were different elsewhere. In Great Britain the county militia (whose special history is briefly sketched below) was permanently embodied during the greater part of the Napoleonic Wars. Destitute as it was of technical and administrative services, of higher staffs and organization, and even of cavalry, this militia was a regular army in all but name. Combining continuous service with territorial recruiting as it did, it consisted of men of a better stamp than the casually recruited regular forces. In those days, the militia was a county force commanded by the lords-lieutenant and officered by men of influence; it was not administered by the War Office.

In other countries, Napoleon's invading armies had only to deal with regular or professional troops. Once these were crushed, nothing remained for the beaten side but to make peace with the conqueror on such terms as could be obtained. Militias existed in name as organizations, for the production of more or less unwilling drafts for the line, but the fundamental militia obligation of defending the *fatherland* as distinct from defending the *state*, produced only local and occasional outbursts of guerrilla warfare. In the Crimean War, the 1859 war in Italy, the 1866 war in Germany, and other wars (the Hungarian War of 1848–49 excepted) the forces, other than the regular troops, engaged in first line were guerrilleros, insurgents, Garibaldians, &c., and behind the forces in first line there were draft-supplying agencies, but no true militia. Only the British militia and the Prussian landwehr represented the self-contained army of second line, and of these the former was never put to the test, while the latter, responding feebly to a political call to arms in 1850, was in consequence so entirely reorganized that it formed a mere rear rank to the line troops. This latter system, consecrated by the German successes of 1870, became the universal model for the continent of Europe, and organized and self-contained militias to-day are only to be found in states maintaining first line armies of "general service" professionals, or in states which maintain no first line troops whatever. In the first class are the auxiliary forces of the British Empire and the United States, in the second the Swiss, Norwegian, Dutch and Swedish forces.

MILITIA OF THE UNITED KINGDOM

The title of "militia" disappeared from the list of the British forces in 1908, on the conversion of the existing self-contained militia into an army "special reserve" which is restricted to the rôle of providing drafts for the first line.[1] The "self-contained" second line army of the present day is the Territorial Force (see UNITED KINGDOM: *Army*).

The county organization of England, with which throughout the militia was closely associated, began with the advent of the Saxons. The prototype of the militia was the Fyrd. In this force as reorganized by Alfred liability of service was general on the part of every able-bodied male between the ages of 16 and 60. Although the title of "The Fyrd" survived until long after the Norman Conquest, the force established by King Alfred was known as the general levy, which was bound to appear armed when ordered to aid in suppressing domestic riots as well as in defending the realm against invasion by foreign foes. Service was restricted to the counties, except in case of invasion, when it was extended to the whole kingdom. For centuries these remained with little alteration as the principles governing the national forces of the kingdom, and form in effect with certain developments the basis of the modern militia system. The Norman Conquest was immediately followed by the introduction of the feudal levy in addition to the general levy, the distinction between these forces being that while obligation to serve in the latter rested upon every male within certain limits of age, service in the feudal levy depended upon tenure of land under the king as feudal lord. The general levy was not in any case liable for service overseas, but the king for a long time employed his feudal tenants in continental wars until they too, successfully resisted the demand. Personal service formed the basis of both levies, but service by deputy, or payment in lieu of personal service, and the calling out of a quota only, were allowed from very early times. The feudal levy was discontinued during the Commonwealth and abolished at the Restoration; but liability to serve in the general levy has never been extinguished, but remains in the statutory and practical form of liability to serve both in the general and local militia. Even at the abolition of these forces the statutory liability to service in them was not done away with. Inspections of arms and the assembly and training of the men raised under this national system were secured from time to time by means of "assizes of arms," "views of armour," "commissions of array," and "commissions of musters," dating from early in the 12th century down to the 16th century. The machinery employed to carry out the law formed the basis of the existing procedure for the enforcement of the ballot for the militia, which thus bears a strong resemblance to the means adopted from ancient times. These constitutional powers were frequently abused by "electing" or impressing men to serve out of the kingdom, but this was checked in the year 1327 by an Act of Parliament, which strictly regulated the scope and limits of military service within the kingdom at the charge of the parishes or counties, but provided for service abroad at the charge of the Crown. "Commissions of musters" were a development of preceding measures for raising men and material for military service, under which the commissioners registered and mustered persons liable to serve, sorted them into bands and trained and exercised them at the charge of the county. These bands became known as *train* or *trained bands*, and were mustered annually. With them were associated lieutenants of counties, first appointed in 1549 by Edward VI., subsequently in Queen Mary's reign called lords lieutenant, and after the Restoration appointed as statutory officers for the militia, their commissions at the present day being issued under the Militia Act. There does not appear to have been any clearly defined regimental organization in existence until these bands or companies were called into active service, but the Acts of the Commonwealth supplied this defect, and initiated a permanent regimental system. One of the earliest attempts to reform the force since the time of King Alfred was made by Charles I. in 1629, when Orders in Council were issued instructing lords lieutenant to put the militia on a better footing and to fill up vacancies among the officers. Cromwell subsequently issued similar orders couched in strong terms, though under the Commonwealth the duties of lords lieutenant were not recognized, the militia being raised by commissioners. The great services rendered by the militia in the "crowning mercy" of Worcester are a historic exception to the general decadence of second line troops in the 17th and 18th centuries (see GREAT REBELLION). At the Restoration an act was passed declaring that the control of the militia was the prerogative of the king. By the same statute the militia of each county was placed under the lieutenant, who was vested with the appointment of officers, but with a reservation to the Crown in the way of commissioning and dismissal. The cost of the annual training—for fourteen days—fell upon the local authority. Offences against discipline were dealt with by the civil magistrates, but with a power to the officers of fining and of imprisoning in default. Upon this footing the militia of England remained for nearly a century with the general approval of the community. It was recognized as an instrument for defence and for the preservation of internal order, while it was especially popular from the circumstance that from its constitution and organization the Crown could not use it as a means of violating the constitution or abridging the liberty of the subject. It was controlled and regulated in the county; it was officered by the landowners and their relatives, its ranks were filled by men not depending for their subsistence or advancement upon the favour of the Crown; its numbers and maintenance were beyond the royal control; its government was by statute. While the supreme command was distinctly vested in the Crown, every practical security was thus taken against its use by the Crown for any object not constitutional or legitimate. It was regarded as, and was, in fact, the army of the state as distinguished from the standing army, which was very much the army of the king personally. The latter consisted of hired soldiers, and was more than once recruited by a conscription, confined, however, to persons of the vagrant class not having a lawful employment, while the former was mainly composed of those having a fixed abode and status. The militia thus enjoyed for many years as compared with the regular forces a social as well as a constitutional superiority. To this, however, along with the general breakdown of militia systems under the new "professional" conditions of warfare, explained above, and perhaps the practice of trying military offences by civil courts, may be attributed the disrepute into which the militia fell and the inefficiency it displayed, with the exception of the trained bands of London, until it was reorganized in 1757. Under the act of 1662 all train bands were discontinued in the counties, but those of London, with their auxiliaries, remained until 1794, when they were reorganized as the City of London Militia. In 1688 an act was passed raising the militia for one year, and for some time it was an annually sanctioned force as the regular army is to-day. In 1690, on the occasion of the threatened French invasion, the militia was embodied; and again in 1715 and 1745 during the troubles caused by the Old and Young Pretenders. In a pamphlet of 1712 the English militia was estimated at 7450 horse and 84,391 foot soldiers. From 1715 until 1734, and again from that year until 1757, with the exception of 1745, no votes were taken in parliament for the militia.

---

[1] Various dominions and colonies of the British Empire have militias, for which see UNITED KINGDOM: *Army*. For the Swiss Militia System, which is in many respects the archetype of modern militias, see SWITZERLAND; and for the organized militia of the United States see UNITED STATES.

The foregoing remarks apply only to the English militia and its predecessors. Ireland and Scotland did not furnish any regular militia until 1715 and 1797 respectively, although in Scotland militia existed long before 1797, *e.g.* in Perthshire in 1684; and in addition corps of fencibles were raised and embodied. The Irish militia when first raised in 1715 was restricted to Protestants between the ages of 16 and 60, who were bound to appear or provide substitutes. The force was not made subject to military law, but various military offences were punishable by fine or imprisonment. Several amendments and other acts followed until 1793, when a new act was passed providing for raising a force of militia by ballot among men between the ages of 18 and 45, to serve for four years. Each county was liable to a fine of £5 for each man deficient, and enlistment in the army was prohibited. Other amendments followed from time to time, and notably one in 1797 abolishing religious restrictions for the supplementary militia, and another in 1802 removing the same restrictions in the case of the general militia. Finally, all the acts were consolidated in 1809 by an act which fixed establishments, provided for raising the men by ballot, but gave power to the lord-lieutenant to authorize voluntary enlistment by means of bounties, and also to suspend the raising of any regiment. The Scottish militia was at first raised by ballot among men between the ages of 19 and 30. In 1802 former acts were replaced by an Act providing for the organization of the militia on a basis similar to that on which the militia of England was organized by the Consolidation Act passed in that year.

To return to England, the immediate cause of the organic reform carried out in 1757 was the disclosure of the inefficiency of the militia during the Rebellion of 1745. The act of 1662 followed the old law by requiring owners of property to furnish men, horses and arms in proportion to the value of their property, and the liability of persons of small property was to be discharged out of a rate levied in the parish. This was entirely altered in 1757, a liability on the part of the county or parish being substituted for a liability on the part of individuals. Each county was required to furnish a quota apportioned among the various parishes; men were to be chosen by lot to serve for three years (this being the first provision of a fixed term of service) or to provide, or pay £10 for the provision of, a substitute, and vacancies were to be filled from time to time by a like process of ballot. The ages of liability were from 18 to 45. The system thus legalized is practically the existing though suspended ballot system. The force was to be annually trained and exercised for a limited period, and in case of invasion or danger thereof, or in case of rebellion, the Crown could order it or any portion of it to be embodied; but only on condition of informing parliament (which was if not sitting to be summoned for the purpose). During the embodiment or annual training it was subject to the Mutiny Act, except that no punishment during training was to extend to "life or limb"; to prevent an unconstitutional use of the militia by the Crown, the estimate for its training was framed each year, not by an executive minister of the sovereign, but by the House of Commons itself. Upon the initiative of a committee of the house, an act was passed providing for the pay and clothing of the militia for the year. The king directly appointed the permanent staff and was given a veto on the appointment and promotion of the officers, who were to have a property qualification.

Under this act 30,000 militiamen were raised by ballot and embodied from 1759 to 1763. This force was exclusively "Protestant," and remained so until 1802. The service of the militia as thus arranged remained nearly in the same state until 1870. Pitt's reform, however, was followed by numerous amendments, new enactments, and other changes, of which the following is a summary in chronological order:—

1758. Men volunteering to serve recognized as counting towards the quota.

1761. Raising of quota made compulsory on counties under penalty of fines.

Mutiny Act applied to militia when out for training as well as when embodied.

1775. (American War.) Act passed empowering embodiment of militia in case of colonial as well as domestic rebellion.

1786. Charge on parishes for storage of arms, &c., transferred to counties.

1795. Enlistment into regulars encouraged.

1796. Supplementary militia formed, consisting of 63,878 men.

1798. (Irish Rebellion.) English militia volunteered for service in Ireland.

1799. Irish militia volunteered to serve in Great Britain.

15,000 militiamen volunteered to regular army.

1803. 45,492 men raised for militia by ballot, but of these 40,998 were substitutes.

1805. Militia affiliated to line for purposes of recruiting for regulars.

1806. Training Act to raise by ballot 200,000 men to be trained for one whole year, and then to discharge them from training for two years.

1808. Difficulties having arisen under above Act, local militia (which is in effect the old general levy) established in addition to general militia then embodied.

27,000 militiamen volunteered to regular army during preceding twelve months.

1811. English militia, hitherto not liable to serve out of the kingdom, now made liable to serve in any part of the United Kingdom under certain restrictions, which were subsequently (in 1859) removed.

Method of obtaining men from militia for regulars further systematized.

1812. In this year there were 250 regiments of local militia, with an establishment of 240,388 men and 214,418 actually enrolled.

1813. During ten years, from 1803 to 1813, nearly 100,000 militiamen joined the regular army.

Act passed to enable militia to serve abroad as militia with their own officers. Three strong battalions joined the British army in France.

1815. Militiamen recruited in great numbers the army which fought at Waterloo.

Local militia ceased to be raised.

1816. Local militia and Ballot Act suspended.

General militia disembodied.

1820–21–25. Militia called out for training.

1829. Act passed suspending ballot for the general militia.

1831. Militiamen raised by ballot in accordance with Order in Council, 27th of December 1830. This was the last occasion on which the ballot was put in force.

In the latter stages of the great French war the tendency of the government was to use the general militia rather as a reservoir producing drafts (in the end whole units) for service abroad, and the local militia as the real defensive force. During the height of the war (in 1812) the relative position of the various branches of the army was as follows: First line, the standing army; second line, the general or regular militia, which as the war went on were more and more used abroad; third line, the local militia, with the survivors of the volunteers, who at that time numbered about 68,000 men. After the peace of 1815 the militia was allowed practically to fall into abeyance, and although the permanent staff was maintained, it had no duties to perform. In 1848 the Prime Minister intimated in parliament his intention to re-establish the militia, but it was not until 1852, after an unsuccessful attempt to resuscitate the local militia, that the general militia of England was reorganized under a system of voluntary enlistment with the ballot in reserve, Scotland and Ireland being included in 1854. The property qualification of officers which had hitherto existed (with exception in favour of ex-officers of the army and navy) was reduced, and after a further reduction in 1854, abolished in 1869. Larger powers respecting the militia were conferred upon the Crown, and during the Crimean War the queen was authorized to embody the militia whenever a state of war existed with any foreign power. In that war the militia was embodied and did garrison duty not only in the United Kingdom but in the Mediterranean garrisons, thus enabling the authorities to send most of the available regular troops to the scene of hostilities. It further contributed many officers and some 30,000 men to the line. During the Indian Mutiny it filled scarcely less useful functions when again called out. The acceptance of voluntary offers of service in the Channel Islands and Isle of Man was definitely authorized in 1859, and extended to service in Malta and Gibraltar in 1875.

In 1871 an important constitutional change was made. It was part of the new army system inaugurated in that year that the control of the militia should be removed from the lord-lieutenant of the county and vested wholly in the Crown. It now virtually ceased to exist as a distinct body, and in 1881 it became a part of the regular forces with a limitation as to the time and area and other conditions of service. Militia battalions were united with the line battalions to form territorial regiments, the artillery and engineers being also closely associated with the regular services. Various amendments and new enactments followed, all in the direction of increasing the usefulness of the militia, rendering it more efficient and readier for service, though at the same time making it more and more a means for supplying recruits, both officers and men, to the regular army. The officers, who were commissioned by the Crown, were in 1877 made subject at all times to military law. Non-commissioned officers and men were only so subject when embodied or out for training, with extension in the case of men convicted of offences committed during training until the expiration of the punishment.[1] Enlistment was voluntary, compulsory service by ballot remained legal, but suspended. The period of engagement was for six years, re-engagements for periods of four years up to the age of 45 being permitted. Bounties were paid to militiamen at various rates upon enlistment, conclusion of training, re-engagement, enlistment into reserve or special service section, and other special circumstances. Recruit training, maximum six months, as a rule did not exceed three months. Recruits were either drilled immediately upon enlistment at any time of the year, which is now the most usual system, or else at preliminary drills (first instituted in 1860), immediately preceding the annual training of the corps. The annual training varied with the different branches of the service. The usual term for infantry was 27 days, but when on manœuvres this was generally extended to 34 days, 56 days being the legal maximum. Artillery and fortress engineers trained for 41 days and submarine mining engineers for 55 days. Trainings took place for the most part in camp or barracks, and large numbers of militia battalions were latterly called on to take part in field manœuvres. The militia dépôts occupied as a rule the same barracks, and officers and men wore (with slight distinctions) the same uniform as the regulars. The militia occupied an important position in the mobilization scheme for national defence. The permanent staff (adjutant, quartermaster, and an establishment of non-commissioned officers and buglers or drummers, all regulars) was engaged during the non-training period of the year in recruiting, care of arms, clothing &c., and in drilling recruits. The general lines of the system, as regards training are still followed with the Special Reserve, though the constitution of the new force is very different.

The militia ordinarily was liable only for service in the United Kingdom, but by legislation in 1899 may voluntarily serve in any part of the world, including India. During 1899–1900, 22,000 militiamen were thus accepted for service abroad, the bulk of them proceeding to the seat of war in South Africa.

The militia reserve consisted of men selected from the ranks of the militia for special enlistment for service in the regular army when called upon in emergencies, in the following proportions to the establishments of the various corps: Artillery, one-third; engineers and infantry, one-fourth; medical staff corps, one-half. The militia reserve was first formed in 1867, and in 1900 numbered 30,000 men. During an emergency in 1878, 20,000 militia reservists joined the regular army. The term "militia" reserve was therefore a complete misnomer, and the force so called was purely an army reserve. The special service section of the militia was formed by royal warrant in 1898, and consisted of (1) militia units and (2) individual militiamen. A militia unit was considered as available for special service if not less than 75 % of the officers and men present at training made a voluntary offer to engage for special service in any part of the world, and if in the infantry at least 500 and in the artillery at least 250 men were accepted as qualified. Individual militiamen engage to serve either with their militia unit if it were registered for service, or else for special service with the regular forces. Liability for service was limited to twelve months. Men of the special service section could also belong to the militia reserve, and receive a bounty in addition to that given for the reserve. The result of this special section was not up to 1900 satisfactory. Very few units could qualify for registration, and the response of individual men was comparatively insignificant.

During and after the South African War, while militia recruiting for the regulars showed a constant increase compared with preceding years, the strength of the militia itself decreased year after year. Its militia character had been diminishing ever since the creation of the "militia reserve" and the close affiliation of the force to the regular army. For good or evil, then, it had become in the first place a draft-producing agency, and on the reorganization of the forces of the Crown into two lines by Mr Haldane the old "constitutional force" was frankly reorganized as a reserve for the line, enlistment and training conditions remaining somewhat similar to those in vogue in the militia, but the liability for service abroad becoming the first and most important condition in the "special reservist's" enlistment.

MILK (O. Eng. *meoluc*; from a common Indo-European root, cf. Lat. *mulgere*, Gr. ἀμέλγειν), the fluid secreted by the mammary glands of the division of vertebrate animals called *Mammalia* (see MAMMARY GLAND), and primarily devised for the nourishment of their own young.

The milk of various domesticated animals is more or less used by man for food. The milk of the cow, which may be taken as typical of all others, and is indeed by far the most important and valuable of all (see DAIRY AND DAIRY FARMING), is, when newly drawn, an opaque white fluid, with a yellowish tinge, soft, bland and sweetish to the taste, and possessed of a faintly animal odour. This odour, according to Schreiner, is due to the presence of sulphuretted hydrogen, and disappears after a short exposure. The specific gravity of milk ordinarily ranges from 1·029 to 1·033, very seldom reaching 1·035 or falling so low as 1·027. In chemical constitution it consists of an emulsion of fatty globules (cream) in a watery alkaline solution of casein, and a variety of sugar, peculiar to milk, called lactose. The fat (which when separated we know as butter) and the lactose constitute the carbonaceous portion of the milk regarded as food. The casein, which forms the principal constituent of cheese, and a certain proportion of albumen which is present, form the nitrogenous, while the complex saline substances and water are the mineral constituents. These various substances are present in the proportions which render milk a perfect and typical food suitable to the wants of the young of the various animals for whom it is provided by nature. The milk of animals, so far as is known, contains them, although they are present in somewhat different proportions. It is probable that the milk of ruminants possesses certain physical and physiological distinctions from that of non-ruminant animals, which will account for the virtues attributed to the milk of the ass and mare. The following table exhibits the chemical constitution of the kinds of milk most frequently used by man:—

---

[1] This, though here mentioned as part of a process of "regularizing" the militia, was in fact a reform that was advisable under any conditions. The new Territorial Force when created out of the Volunteer Force (which had no such liabilities except when training or serving with regulars) was made subject to military law, officers at all times, men whenever under instruction.

	Cow.		Goat.	Ewe.[1]	Mare.	Ass.	Human.
	Winter Blyth.	Cameron.	Voelcker.	Voelcker.	Cameron.	Chevallier and Henry.	Gerber.
Water . .	86·87	87·00	84·48	83·70	90·310	91·65	88·02
Fat . . .	3·50	4·00	6·11	4·45	1·055	0·11	2·90
Casein and albumin .	4·75	4·10	3·94	5·16	1·953	1·82	1·60
Sugar . . .	4·00	4·28	4·68	5·73	6·285	6·08	7·03
Ash . . .	0·70	0·62	0·79	0·96	0·369	0·34	0·31

In addition to these constituents milk contains small proportions of the gases carbonic acid, sulphuretted hydrogen, nitrogen and oxygen, and minute quantities of other principles, the constant presence and essential conditions of which have not been determined. These consist of galactin and lactochrome, substances peculiar to milk, discovered by Winter Blyth, with certain animal principles such as leucin, pepton, kreatin, tyrosin, &c. The salts in milk consist, according to the average of numerous analyses by Fleischmann, of the following constituents:—

Phosphoric acid . .	28·31	Potash	17·34
Chlorine	16·34	Magnesia	4·07
Lime	27·00	Ferric oxide . . .	0·62
Soda	10·00		

Milk thus is not to be regarded as a definite chemical compound nor even as a mixture of bodies in fixed and invariable proportions. Not only does the milk of different races and breeds of cows vary within comparatively wide limits; the milk of the same animal is subject to extensive fluctuation. The principal causes of variation in the individual are age, period of lactation, nature and amount of food, state of health, and treatment, such as frequency of milking, &c. The following table indicates the range of normal variations:—

Water	90·00 to 83·65
Fat	2·80 ,, 4·50
Casein and albumin	3·30 ,, 5·55
Sugar	3·00 ,, 5·50
Ash	0·70 ,, 0·80

The average quantity of milk yielded by cows is also highly variable, both in individuals and breeds.

Milk and Disease.—Although the milk of a perfectly healthy cow may be absolutely sterile, it is difficult to obtain it in that condition. In the report of the joint committee appointed for the purpose by the county boroughs of Bradford, Hull, Leeds, Rotherham and Sheffield in 1908, the following conclusions were drawn: (1) Cows' milk freshly drawn from the udder by ordinary methods contains bacteria. They are more numerous in the first flow of the milk. (2) There is a great increase in contamination in the milk at each stage before it reaches the customer. This is due to (*a*) the dirty condition of the cows' udders, (*b*) the imperfect cleansing of the cans and of the hands of the milkers. The committee recommend: "(1) The washing of the udder and flanks with soap and water, and similar attention to the hands of the milker. (2) Efficient sterilization of all vessels by steam if possible, or by abundance of boiling water. (3) Rejection of the first draw of the milk from each teat. (4) Avoidance of any work raising dust immediately before or during milking. (5) Removal of the milk of each cow immediately from the shed. (6) Ventilation and cleanliness of the cowsheds." This provides for the reduction as far as possible of contamination during the milking process itself. As any bacteria present in the milk tend to multiply rapidly on the way to the consumer, it is mainly a question of the time which elapses before consumption. It is, therefore, further recommended (*a*) that the milk be rapidly cooled or chilled, as the lower the temperature the less do the bacteria multiply, (*b*) that contamination during railway transit be avoided by dust-proof locked milk cans.

By treating milk at a temperature of 60° C. for one hour, 70° C. for ten minutes, and 95° C. for one minute, tubercle bacilli, if present, will certainly be killed. Cholera and typhoid organisms are less resistant, and are killed more quickly than tubercle bacilli at the above temperatures. Only a single pathogenic species can withstand the short boiling to which milk is ordinarily treated in domestic management, and this is the anthrax bacillus containing spores. The danger from this source is remote, as the microbe does not form spores within the animal body. Even in the worst cases, therefore, only vegetable forms, easily destroyed by boiling, can find their way into the milk from the body of the cow.

The lactic acid bacillus, always present in unboiled milk (to which the souring of milk is due), is easily destroyed by heat; but the *bacillus mesentericus*, often found in it, forms spores, which are not destroyed by ordinary boiling, and germinate when the milk is kept at a moderately warm temperature, producing a brisk fermentation whereby a large volume of gas is liberated. The fundamental idea of Soxhlet's method for sterilizing milk is to boil it for forty minutes in small bottles holding just enough for one meal, and closing the same with an impervious stopper, which is only removed just before use. Milk so treated will keep at the ordinary room temperature, as the spores of the *B. mesentericus* do not develop below 15° C.; but if it be introduced into the alimentary canal of a child the spores will rapidly multiply, and in such cases large quantities of gas, giving rise to flatulency, will be formed, and possibly also poisonous decomposition products of albuminoid matter. To render milk sterile in the strict sense of the word it is necessary to raise it to a temperature of about 120° C. for twenty minutes. Under these conditions the lactose decomposes into dark-brown fission products, the fat loses its emulsified condition and separates out as cream which cannot be made to diffuse again even by shaking, and the albuminoids are converted into a form very difficult of digestion.

In short, there is the greatest difficulty in freeing milk on a large scale from germs without at the same time seriously prejudicing its flavour and nutritive value. Since, then, the destruction of the hardy germs is so difficult, the greater care should be taken, by washing the udder, hands and milk vessels, to secure extreme cleanliness in the preparation of milk intended for infant consumption. Sterilization then becomes an easier task, the milk drawn under these conditions being very poor in spore-forming bacteria. It is imperative that cream destined for butter-making should be free from pathogenic organisms. The organisms of cholera, typhoid fever and tuberculosis present in butter retain their vitality for a long time. As butter is consumed in the raw state, a trustworthy preliminary treatment of the cream is in the highest degree desirable. Schuppan has shown that it is possible to produce good butter from Pasteurized or even sterilized cream, and Weigmann introduced the plan of artificially souring cream by means of pure cultures of *B. acidi lactici*.

Since Metchnikoff's introduction (see LONGEVITY) of the use of soured milk for dietetic purposes—the lactic acid bacillus destroying pathogenic bacteria in the intestine—a great impetus has been given to the multiplication of laboratory preparations containing cultures of the bacillus; and in recent years much benefit to health has, in certain cases, been derived from the discovery.

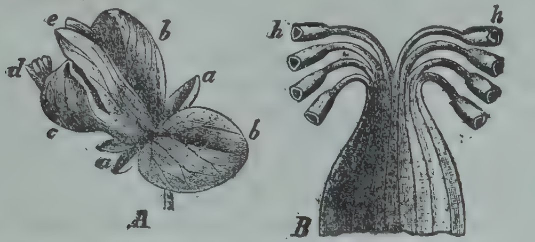
MILKWORT, in botany, the common name for plants of the genus *Polygala* (natural order Polygalaceae), a large genus widely dispersed in temperate and tropical regions and represented by a few species in Britain. The common species, *P. vulgaris*, is a small wiry perennial found on heaths and in meadows throughout the British Isles. The stems are 2 to 10 in. long and bear narrow rather tough leaves and small, ⅙ to ⅓ in. long, white, pink, blue, lilac or purple flowers. The flowers (see fig.) are peculiar in form and arrangement of parts; they have five free sepals the two inner of which (*b*) are large petaloid and winglike, forming the most conspicuous part of the flower; the petals are united below with the sheath of the eight stamens forming a tube split at the base behind; their form recalls that of the pea family. The name *Polygala* is from the Greek πολὺς, much, and γάλα, milk, the plant being supposed to increase the yield of milk in cows. Some species with showy flowers are known in cultivation as greenhouse, or hardy annual or perennial, herbs or shrubs. The root of *P. Senega*, snake-root, a North American species is officinal. Sea milkwort is the common name for *Glaux maritima*, a small succulent herb found on seashores and in estuaries in the British Isles; it belongs to the primrose order (Primulaceae).

---

[1] Ewe's milk is exceedingly variable, especially in its percentage of fat. The above analysis is one of nine by Dr Arthur Voelcker, in which the fat was found to range from about 2 to 12¾%.



After Berg & Schmidt, from Strasburger's *Lehrbuch der Botanik*, by permission of Gustav Fischer.

Polygala Senega.

A, Flower; *a*, small sepals; *b*, large sepals; *c*, keel, representing the anterior petal; *d*, its fimbriated edge; *e*, lateral petals.

B, The 8 stamens united into a sheath below; *h*, anthers (magnified).

MILL, JAMES (1773–1836), historian and philosopher, was born on the 6th of April 1773, at Northwater Bridge, in the parish of Logie-Pert, Forfarshire, the son of James Mill, a shoemaker. His mother, Isabel Fenton, of a good family which had suffered from connexion with the Stuart rising of 1745, resolved that he should receive a first-rate education, and sent him first to the parish school and then to the Montrose Academy, where he remained till the unusual age of seventeen and a half. He then entered the university of Edinburgh, where he distinguished himself as a Greek scholar. In October 1798 he was licensed as a preacher, but met with little success. From 1790 to 1802, in addition to holding various tutorships, he occupied himself with historical and philosophical studies. Finding little prospect of a career in Scotland, in 1802 he went to London in company with Sir John Stuart, then member of parliament for Kincardineshire, and devoted himself to literary work. From 1803 to 1806 he was editor of an ambitious periodical called the *Literary Journal*, which professed to give a summary view of all the leading departments of human knowledge. During this time he also edited the *St James's Chronicle*, belonging to the same proprietor. In 1804 he wrote a pamphlet on the corn trade, arguing against a bounty on the exportation of grain. In 1805 he published a translation (with notes and quotations) of C. F. Villers's work on the Reformation, an unsparing exposure of the alleged vices of the papal system. In 1805 he married Harriet Burrow, whose mother, a widow, kept an establishment for lunatics in Hoxton. He then took a house in Pentonville, where his eldest son, John Stuart Mill (*q.v.*), was born in 1806. About the end of this year he began his *History of India*, which he took twelve years to complete, instead of three or four, as he had expected.

In 1808 he became acquainted with Jeremy Bentham, and was for many years his chief companion and ally. He adopted Bentham's principles in their entirety, and determined to devote all his energies to bringing them before the world. Between 1806 and 1818 he wrote for the *Anti-Jacobin Review*, the *British Review* and the *Electric Review*; but there is no means of tracing his contributions. In 1808 he began to write for the *Edinburgh Review*, to which he contributed steadily till 1813, his first known article being "Money and Exchange." He also wrote on Spanish America, China, General Miranda, the East India Company, and the Liberty of the Press. In the *Annual Review* for 1808 two articles of his are traced—a "Review of Fox's History," and an article on "Bentham's Law Reforms," probably his first published notice of Bentham. In 1811 he co-operated with William Allen (1770–1843), quaker and chemist, in a periodical called the *Philanthropist*. He contributed largely to every number—his principal topics being Education, Freedom of the Press, and Prison Discipline (under which he expounded Bentham's "Panopticon"). He made powerful onslaughts on the Church in connexion with the Bell and Lancaster controversy, and took a prominent part in the discussions which led to the foundation of London University in 1825. In 1814 he wrote a number of articles, containing an exposition of utilitarianism, for the supplement to the fifth edition of the *Encyclopaedia Britannica*, the most important being those on "Jurisprudence," "Prisons" and "Government."

In 1818 the *History of India* was published, and obtained a great and immediate success. It brought about a change in the author's position. The year following he was appointed an official in the India House, in the important department of the examiner of Indian correspondence. He gradually rose in rank till he was appointed, in 1830, head of the office, with a salary of £1900, raised in 1836 to £2000. His great work, the *Elements of Political Economy*, appeared in 1821 (3rd and revised ed. 1826).

From 1824 to 1826 Mill contributed to the *Westminster Review*, started as the organ of his party, a number of articles in which he attacked the *Edinburgh* and *Quarterly Reviews* and ecclesiastical establishments. In 1829 appeared the *Analysis of the Human Mind*. From 1831 to 1833 Mill was largely occupied in the defence of the East India Company, during the controversy attending the renewal of its charter, he being in virtue of his office the spokesman of the court of directors. For the *London Review*, founded by Sir William Molesworth in 1834, he wrote a notable article entitled "The Church and its Reform," which was much too sceptical for the time, and injured the *Review*. His last published book was the *Fragment on Mackintosh* (1835). He died on the 23rd of June 1836.

Mill had a thorough acquaintance with Greek and Latin literature, general history, political, mental and moral philosophy. His intellect was logical in the highest degree; he was clear and precise, an enemy of loose reasoning, and quick to refute prevailing fallacies. All his work is marked by original constructive thought, except in a few subjects, in which he confessedly expounded Bentham's views. At a time when social subjects were as a rule treated empirically, he brought first principles to bear at every point. His greatest literary monument is the *History of India*. The materials for narrating the acquisition by England of its Indian Empire were put into shape for the first time; a vast body of political theory was brought to bear on the delineation of the Hindu civilization; and the conduct of the actors in the successive stages of the conquest and administration of India was subjected to a severe criticism. The work itself, and the author's official connexion with India for the last seventeen years of his life, effected a complete change in the whole system of governing that country.

Mill played a great part also in English politics, and was, more than any other man, the founder of what was called "philosophic radicalism." His writings on government and his personal influence among the Liberal politicians of his time determined the change of view from the French Revolution theories of the rights of man and the absolute equality of men to the claiming of securities for good government through a wide extension of the franchise. Under this banner it was that the Reform Bill was fought and won. His *Elements of Political Economy*, which was intended only as a textbook of the subject, shows all the author's precision and lucidity. As Dr J. K. Ingram said, it has the "character of a work of art." It followed up the views of Ricardo, with whom Mill was always on terms of intimacy. Its interest is mainly historical, as an accurate summary of views which are now largely discarded. Among the more important of its theses are: (1) that the chief problem of practical reformers is to limit the increase of population, on the assumption that capital does not naturally increase at the same rate as population (ii. § 2, art. 3); (2) that the value of a thing depends entirely on the quantity of labour put into it; and (3) that what is now known as the "unearned increment" of land is a proper object for taxation. The work as a whole is a striking example of the weakness of treating economic problems from a purely a priori standpoint by the deductive method.

By his *Analysis of the Mind* and his *Fragment on Mackintosh* Mill acquired a position in the history of psychology and ethics. He took up the problems of mind very much after the fashion of the Scottish school, as then represented by Reid, Stewart and Brown, but made a new start, due in part to Hartley, and still more to his own independent thinking. He carried out the principle of association into the analysis of the complex emotional states, as the affections, the aesthetic emotions and the moral sentiment, all which he endeavoured to resolve into pleasurable and painful sensations. But the salient merit of the *Analysis* is the constant endeavour after precise definition of terms and clear statement of doctrines. The *Fragment on Mackintosh* is a severe exposure of the flimsiness and misrepresentations of Sir James Mackintosh's famous *Dissertation on the Progress of Ethical Philosophy* (1830), and discusses the foundations of ethics from the author's utilitarian point of view.

MILL, JOHN (*c.* 1645–1707), English theologian, was born about 1645 at Shap in Westmorland, entered Queen's College, Oxford, as a servitor in 1661, and took his master's degree in 1669 in which year he spoke the "Oratio Panegyrica" at the opening of the Sheldonian Theatre. Soon afterwards he was chosen fellow and tutor of his college; in 1676 he became chaplain to the bishop of Oxford, and in 1681 he obtained the rectory of Bletchington, Oxfordshire, and was made chaplain to Charles II. From 1685 till his death he was principal of St Edmund's Hall; and in 1704 he was nominated by Queen Anne to a prebendal stall in Canterbury. He died on the 23rd of June 1707, just a fortnight after the publication of his Greek Testament.

Mill's *Novum testamentum græcum, cum lectionibus variantibus MSS. exemplarium, versionum, editionum SS. patrum et scriptorum ecclesiasticorum, et in easdem notis* (Oxford, fol. 1707), was undertaken by the advice and encouragement of John Fell (*q.v.*), his predecessor in the field of New Testament criticism; it represents the labour of thirty years, and is admitted to mark a great advance on all that had previously been achieved. The text indeed is that of R. Stephanus (1550), but the notes, besides embodying all previously existing collections of various readings, add a vast number derived from his own examination of many new MSS, and Oriental versions (the latter unfortunately he used only in the Latin translations). Though the amount of information given by Mill is small compared with that in modern editions, it is probable that no one person, except perhaps Tischendorf, has added so much material for the work of textual criticism. He was the first to notice, though only incidentally, the value of the concurrence of the Latin evidence with the Codex Alexandrinus, the only representative of an ancient non-Western Greek text then sufficiently known; this hint was not lost on Bentley (see Westcott and Hort, *Introduction to New Testament*). Mill's various readings, numbering about thirty thousand, were attacked by Daniel Whitby (1638–1726) in his *Examen* as destroying the validity of the text; Antony Collins also argued in the same sense though with a different object. The latter called forth a reply from Bentley (*Phileleutherus lipsiensis*). In 1710 Kuster reprinted Mill's Testament at Amsterdam with the readings of twelve additional MSS.

MILL, JOHN STUART (1806–1873), English philosopher and economist, son of James Mill, was born on the 20th of May 1806 in his father's house in Pentonville, London. He was educated exclusively by his father, who was a strict disciplinarian, and at the age of three was taught the Greek alphabet and long lists of Greek words with their English equivalents. By his eighth year he had read Aesop's *Fables*, Xenophon's *Anabasis*, and the whole of Herodotus, and was acquainted with Lucian, Diogenes Laërtius, Isocrates and six dialogues of Plato (see his *Autobiography*). He had also read a great deal of history in English—Robertson's histories, Hume, Gibbon, Robert Watson's *Philip II.* and *Philip III.*, Hooke's *Roman History*, part of a translation of Rollin's *Ancient History*, Langhorne's *Plutarch*, Burnet's *History of My Own Times*, thirty volumes of the *Annual Register*, Millar's *Historical View of the English Government*, Mosheim's *Ecclesiastical History*, M'Crie's *Knox*, and two histories of the Quakers. A contemporary record of Mill's studies from eight to thirteen is published in Bain's sketch of his life. It shows that the *Autobiography* rather understates the amount of work done. At the age of eight he began Latin, Euclid, and algebra, and was appointed schoolmaster to the younger children of the family. His main reading was still history, but he went through all the Latin and Greek authors commonly read in the schools and universities, besides several that are not commonly read by undergraduates. He was not taught to compose either in Latin or in Greek, and he was never an exact scholar; it was for the subject matter that he was required to read, and by the age of ten he could read Plato and Demosthenes with ease. His father's *History of India* was published in 1818; immediately thereafter, about the age of twelve, John began a thorough study of the scholastic logic, at the same time reading Aristotle's logical treatises in the original. In the following year he was introduced to political economy and studied Adam Smith and Ricardo with his father.

Not unnaturally the training which the younger Mill received has aroused amazement and criticism; and it is reasonable to doubt whether the material knowledge which he retained in the result was as valuable to him as his father imagined. It is important, however, to note that the really important part of the training was the close association which it involved with the strenuous character and vigorous intellect of his father. From his earliest days he spent much time in his father's study and habitually accompanied him on his walks in North London. Much therefore of what he acquired was assimilated without difficulty, and the accuracy of his impressions was tested by his subsequently drafting a *résumé* of their conversations. He thus learned early to grapple with difficulties and to accustom himself to the necessity of precision in argument and expression. It was an inevitable result of such an education that Mill acquired many of his father's speculative opinions, and his father's way of defending them. But he did not receive the impress passively and mechanically. "One of the grand objects of education," according to the elder Mill, "should be to generate a constant and anxious concern about evidence." The duty of collecting and weighing evidence for himself was at every turn impressed upon the boy; he was taught to accept no opinion on authority. He was deliberately educated as an apostle, but it was as an apostle of reasoned truth in human affairs, not as an apostle of any system of dogmatic tenets. It was to prevent any falling off from this high moral standard till it should become part of his being that his father kept the boy so closely with himself. Mill expressly says that his childhood was not unhappy. It seems unhappy only when we compare it with the normal life of a boy and decline to imagine its peculiar enjoyments and aspirations. Mill complains that his father often required more than could be expected of him, but his tasks were not so severe as to prevent him from growing up a healthy and high-spirited boy, though he was not constitutionally robust, and his pursuits were so different from those of other boys of the same age.

From May 1820 till July 1821 Mill was in France in the family of Sir Samuel Bentham, brother of Jeremy Bentham. Away from his father he maintained his laborious habits. Copious extracts from a diary kept by him at this time are given by Bain; they show how methodically he read and wrote, studied chemistry and botany, tackled advanced mathematical problems, made notes on the scenery and the people and customs of the country. He also gained a thorough acquaintance with the French language. On his return in 1821 he added to his work the study of psychology, and that of Roman law, which he read with John Austin, his father having half decided on the bar as the best profession open to him. In 1822, however, when he had just completed his seventeenth year, this intention was abandoned, and he entered as a clerk in the examiner's office of the India House, "with the understanding that he should be employed from the beginning in preparing drafts of despatches, and be thus trained up as a successor to those who then filled the highest departments of the office."

Mill's work at the India House, which was henceforth his livelihood, did not come before the public; hence some have scouted his political writings as the work of an abstract philosopher, entirely unacquainted with affairs. From the first he was more than a clerk, and after a short apprenticeship he was promoted, in 1828, to the responsible position of assistant-examiner with a salary of £600 a year. The duty of the so-called examiners was to examine the letters of the agents of the Company in India, and to draft instructions in reply. The character of the Company's government was almost entirely dependent upon their abilities as statesmen. For twenty years, from 1836 (when his father died) to 1856, Mill had charge of the Company's relations with the native states, and in 1856 he became chief of the office with a salary of £2000. In the hundreds of despatches that he wrote in this capacity, much, no doubt, was done in accordance with established routine, but few statesmen of his generation had a wider experience of the responsible application of the principles of government. About this work he said little in the *Autobiography*, probably because his main concern there was to expound the influences that effected his moral and mental development.

About the time of his entering the India House Mill read Dumont's exposition of Bentham's doctrines in the *Traité de Législation*, which made a lasting impression upon him. When he laid down the last volume, he says, he had become a different being. It gave unity to the detached and fragmentary parts of his knowledge and beliefs. The impression was confirmed by the study of the English psychologists, as well as Condillac and Helvetius, and in 1822–1823 he established among a few friends the "Utilitarian" Society, taking the word, as he tells us, from Galt's *Annals of the Parish*. Two newspapers were open to him—the *Traveller*, edited by a friend of Bentham's, and the *Morning Chronicle*, edited by his father's friend Black. One of his first efforts was a solid argument for freedom of discussion, in a series of letters to the *Chronicle* apropos of the prosecution of Richard Carlile. But he watched all public incidents with a vigilant eye, and seized every passing opportunity of exposing departures from sound principle in parliament and courts of justice. Another outlet was opened up for him (April 1824) by the starting of the *Westminster Review*, and still another in the following year in the *Parliamentary History and Review*. This year also he found a congenial occupation in editing Bentham's *Rationale of Judicial Evidence*. All the time, his mind full of public questions, he discussed eagerly with the many men of distinction who came to his father's house. He engaged in set discussions at a reading society formed at Grote's house in 1825, and in set debates at a Speculative Society formed in the same year.

From the *Autobiography* we learn that in 1826 Mill's enthusiasm was checked by a misgiving as to the value of the ends which he had set before him. This expression was the result, no doubt, of his strenuous training and the comparative lack of congenial friendships. His father was reserved, undemonstrative even to the pitch of chilling sternness, and among young Mill's comrades contempt of feeling was almost a watchword. Himself absorbed in abstract questions and projects of general philanthropy, he had been careless of personal attachment. On the other hand without experience he could not have been prepared for the actual slowness of the reformer's work. In 1826 he looked back to four years of eager toil. What were the results? He had become convinced that his comrades in the Utilitarian Society, never more than ten, had not the stuff in them for a world-shaking propaganda; the society itself was dissolved; the *Parliamentary Review* was a failure; the *Westminster* did not pay its expenses; Bentham's *Judicial Evidence* produced little effect on the reviewers. His own reception at the Speculative Debating Society, where he first measured his strength in public conflict, was calculated to produce self-distrust. He found himself looked upon with curiosity as a precocious phenomenon, a "made man," an intellectual machine set to grind certain tunes. The outcome of this period of depression was a broadening of his outlook on the problems which he had set himself to solve. He now saw that regard for the public good was too vague an object for the satisfaction of a man's affections. It is a proof of the dominating force of his father's character that it cost the younger Mill such an effort to shake off his stern creed about poetry and personal emotion. Like Plato, the elder Mill would have put poets under ban as enemies of truth, and he subordinated private to public affections. Landor's maxims of "few acquaintances, fewer friends, no familiarities" had his cordial approval. These doctrines the younger Mill now felt himself forced in reason to abandon. Too much in awe of his father to make him a confidant, he wrestled in the gloomy solitude of his own mind. He gained from the struggle a more catholic view of human happiness, at delight in the poetry of nature and the affections as well as the poetry of heroic unselfishness, a disposition to study more sympathetically the point of view of opponents, a more courteous style of polemic, a hatred of sectarianism, an ambition, no less noble and disinterested, but moderated to practical possibilities.

In the course of the next few years he wrote comparatively little, but he continued his reading, and also derived much benefit from discussions held twice a week at Grote's house in Threadneedle Street. Gradually also he had the satisfaction of seeing the debates in the Speculative Society becoming famous enough to attract men with whom it was profitable for him to interchange opinions, among others Mauriçe and John Sterling. He ceased to attend the society in 1829, but he carried away from it the strengthening memory of failure overcome by persevering effort, and the important doctrinal conviction that a true system of political philosophy was "something much more complex and many-sided than he had previously had any idea of, and that its office was to supply, not a set of model institutions but principles from which the institutions suitable to any given circumstances might be deduced."

The first sketch of Mill's political philosophy appeared in a series of contributions to the *Examiner* in the autumn of 1830 entitled "Prospects in France." He was in Paris soon after the July Revolution, and made the acquaintance of the leading spirits among the younger men; in his discussion of their proposals we find the germs of many thoughts afterwards more fully developed in his *Representative Government*. It is from this time that Mill's letters supply a connected account of his life (see Hugh Elliott, *Letters of John Stuart Mill*, 1910).

The letters in the *Examiner* may be taken as marking the close of his period of meditative search, and his return to hopeful aspiring activity. It was characteristic of his nature that he should be stirred to such delight by the Revolution in France, and should labour so earnestly to make his countrymen understand with what gravity and sobriety it had been effected. Their own Reform Bill came soon after and it is again characteristic of Mill—at once of his enthusiasm and of his steady determination to do work that nobody else seemed able or willing to do—that we find him in the heat of the struggle in 1831 writing to the *Examiner* a series of letters on "The Spirit of the Age" which drew from Carlyle the singular exclamation "Here is a new mystic!" How little this criticism was justified may be seen from the fact that Mill's inductive logic was the direct result of his aspirations after political stability as determined by the dominion of the wisest (*Examiner* letters). "Why is it," he asked, "that the multitude accept implicitly the decisions of the wisest, of the specially skilled, in physical science?" Because in physical science there is all but complete agreement in opinion. "And why this agreement?" Because all accept the same methods of investigation, the same tests of truth. Is it possible then to obtain unanimity as to the methods of arriving at conclusions in social and political matters, so as to secure similar agreement of opinion among the specially skilled, and similar general respect for their authority? The same thought appears in a review of Herschel's *Natural Philosophy*, written about the same time. Mill remarks that the uncertainty hanging over the very elements of moral and social philosophy proves that the means of arriving at the truth in those sciences are not yet properly understood. "And whither," he adds, "can mankind so advantageously turn, in order to learn the proper means, and to form their minds to the proper habits, as to that branch of knowledge in which by universal acknowledgment the greatest number of truths have been ascertained, and the greatest possible degree of certainty arrived at?"

By 1831 the period of depression had passed; Mill's enthusiasm for humanity had been thoroughly reawakened, and had taken the definite shape of an aspiration to supply an unimpeachable method of search for conclusions in moral and social science. No mystic ever worked with warmer zeal than Mill. But his zeal encountered a check which baffled him for several years, and which left its mark in various inconsistencies and incoherences in his completed system. He had been bred by his father in a great veneration for the syllogistic logic as an antidote against confused thinking. He attributed to his early discipline in this logic an impatience of vague language which in all likelihood was really fostered in him by his study of the Platonic dialogues and of Bentham, for he always had in himself more of Plato's fertile ingenuity in canvassing the meaning of vague terms than the schoolman's rigid consistency in the use of them. Be this as it may, enthusiastic as he was for a new logic that might give certainty to moral and social conclusions, Mill was no less resolute that the new logic should stand in no antagonism to the old. In his *Westminster* review of Whately's *Logic* in 1828 (invaluable to all students of the genesis of Mill's logic) he appears, curiously enough, as an ardent and brilliant champion of the syllogistic logic against highfliers such as the Scottish philosophers who talk of "superseding" it by "a supposed system of inductive logic." His inductive logic must "supplement and not supersede." But for several years he searched in vain for the means of concatenation.

Meantime, while recurring again and again, as was his custom, to this cardinal difficulty, Mill worked indefatigably in other directions where he saw his way clear. The working of the new order in France, and the personalities of the leading men, had a profound interest for him; he wrote on the subject in the *Examiner*. He had ceased to write for the *Westminster* in 1828; but during the years 1832 and 1833 he contributed many essays to *Tait's Magazine*, the *Jurist*, and the *Monthly Repository*. In 1835 Sir William Molesworth founded the *London Review* with Mill as editor; it was amalgamated with the *Wesminster* (as the *London and Westminster Review*) in 1836, and Mill continued editor (latterly proprietor also) till 1840. Much of what he wrote then was subsequently incorporated in his systematic works: some of his essays were reprinted in his first two volumes of *Dissertations and Discussions* (1859). The essays on Bentham and Coleridge constituted the first manifesto of the new spirit which Mill sought to breathe into English Radicalism. But the reprinted papers give no just idea of the immense range of Mill's energy at this time. His position in the India Office, where alone he did work enough for most men, cut him off from entering parliament; but he laboured hard though ineffectually to influence the legislature from without by combating the disposition to rest and be thankful. In his *Autobiography* he admits that the attempt to form a Radical party in parliament at that time was chimerical.

It was in 1837, on reading Whewell's *Inductive Sciences* and re-reading Herschel, that Mill at last saw his way clear both to formulating the methods of scientific investigation and joining on the new logic as a supplement to the old. The *Logic* was published in 1843. In 1844 appeared his *Essays on Some Unsettled Questions in Political Economy*. These essays were worked out and written many years before, and show Mill in his first stage as a political economist. Four out of the five essays are elaborate and powerful solutions of perplexing technical problems—the distribution of the gains of international commerce, the influence of consumption on production, the definition of productive and unproductive labour, the precise relations between profits and wages. Though Mill appears here purely as the disciple of Ricardo, striving after more precise statement, and reaching forward to further consequences, we can well understand in reading these essays how about the time when he first sketched them he began to be conscious of power as an original and independent thinker.

That originality and independence became more conspicuous when he reached his second stage as a political economist, struggling forward towards the standpoint from which his systematic work was written. It would seem that in his fits of despondency one of the thoughts that marred his dreams of human improvement was the apparently inexorable character of economic laws, condemning thousands of labourers to a cramped and miserable existence, and thousands more to semi-starvation. From this oppressive feeling he found relief in the thought set forth in the opening of the second book of his *Political Economy*—that, while the conditions of production have the necessity of physical laws, the distribution of what is produced among the various classes of producers is a matter of human arrangement, dependent upon alterable customs and institutions. There can be little doubt that this thought, whether or not in the clear shape that it afterwards assumed, was the germ of all that is most distinctive in his system of political economy. This system, which for many years subsequently was regarded as authoritative, has been subjected to vigorous criticism by later economists, and it is perhaps not too much to say that it now possesses mainly an historical interest. Its chief importance is perhaps the stress which it laid on the vital connexion which must subsist between true economic theory and the wider facts of social and national development.

While his great systematic works were in progress, Mill wrote very little on events or books of the day. He turned aside for a few months from his *Political Economy* during the winter of the Irish famine (1846–1847) to advocate the creation of peasant-proprietorships as a remedy for distress and disorder in Ireland. He found time also to write elaborate articles on French history and Greek history in the *Edinburgh Review* apropos of Michelet, Guizot and Grote, besides some less elaborate essays.

The *Political Economy* was published in 1848. Mill could now feel that his main work was accomplished; he remained, however, on the alert for opportunities of useful influence, and pressed on with hardly diminished enthusiasm in his search for useful truth. Among other things, he made a more thorough study of socialist writers, with the result that, though he was not converted to any of their schemes as being immediately practicable, he began to look upon some more equal distribution of the produce of labour as a practicability of the remote future, and to dwell upon the prospect of such changes in human character as might render a stable society possible without the institution of private property. This he has called his third stage as a political economist, and he says that he was helped towards it by the lady, Mrs Taylor,[1] who became his wife in 1851. It is generally supposed that he writes with a lover's extravagance about this lady's powers when he compares her with Shelley and Carlyle. But a little reflection will show that he wrote with his usual accuracy and sobriety when he described her influence on him. He expressly says that he owed none of his technical doctrine to her, that she influenced only his ideals of life for the individual and for society; the only work perhaps which was directly inspired by her is the essay on the enfranchisement of women (*Dissertations*, vol. ii.). It is obvious from what he says that his inner life became very different after he threw off his father's authority. This new inner life was strengthened and enlarged by Mrs Taylor.

During the seven years of his married life Mill published less than in any other period of his career, but four of his most closely reasoned and characteristic works, the *Liberty*, the *Utilitarianism*, the *Thoughts on Parliamentary Reform*, and the *Subjection of Women*, besides his posthumously published essays on *Nature* and on the *Utility of Religion*, were thought out and partly written in collaboration with his wife. In 1856 he became head of the examiner's office in the India House, and for two years, till the dissolution of the Company in 1858, his official work, never a light task, kept him fully occupied. It fell to him as head of the office to write the defence of the Company's government of India when the transfer of its powers was proposed. Mill was earnestly opposed to the transfer, and the documents in which he substantiated the proud boast for the Company that "few governments, even under far more favourable circumstances, have attempted so much for the good of their subjects or carried so many of their attempts to a beneficial issue," and exposed the defects of the proposed new government, are models of trenchant and dignified pleading.

---

[1] Mrs Taylor (Harriet Hardy) was the wife of John Taylor, a wholesale druggist in the city of London. She was a confirmed invalid, and lived in the country, where Mill visited her regularly for twenty years, with the full consent of her husband, a man of limited mental powers, but of high character and unselfishness. Mill's friendship with Mrs Taylor and their marriage in 1851 involved a break with his family (apparently due to his resentment at a fancied slight, not to any bitterness on their part), and his practical disappearance from society. (On these points see Mary Taylor, Mrs Mill's grand-daughter, in Elliott's edition of the *Letters*.)

On the dissolution of the Company Mill was offered a seat in the new council, but declined, and retired with a pension of £1500. His retirement from official work was followed almost immediately by his wife's death at Avignon, whither they had come in the course of a tour. So great was the shock that for the rest of his life he spent most of his time at a villa at St Véran, near Avignon, returning to his Blackheath residence only for a short period in each year. He sought relief in active literary occupation, in politics, sociology and psychology. He published, with a touching dedication to his wife, the treatise on *Liberty*, which they had wrought out together. He then turned to politics, and published, in view of the impending Reform Bill, a pamphlet on parliamentary reform. The chief feature in this was an idea concerning which he and Mrs Mill often deliberated —the necessity of providing checks against uneducated democracy. His suggestion of a plurality of votes, proportioned to the elector's degree of education, was avowedly put forward only as an ideal; he admitted that no authentic test of education could for the present be found. An anonymous Conservative caught at the scheme in another pamphlet, proposing income as a test. Soon after Mill supported in *Fraser's*, still with the same object, Hare's scheme for the representation of minorities. In the autumn of the same year he turned to psychology, reviewing Bain's works in the *Edinburgh Review*. In his *Representative Government* (1860) he systematized opinions already put forward in many casual articles and essays. His *Utilitarianism* (published in *Fraser's* in 1861) was a closely-reasoned systematic attempt to answer objections to his ethical theory and remove misconceptions of it. He was especially anxious to make it clear that he included in "utility" the pleasures of the imagination and the gratification of the higher emotions, and to show how powerfully the good of mankind as a motive appealed to the imagination. His next treatise, *The Subjection of Women*, was not published till 1869.[1] His *Examination of Hamilton's Philosophy*, published in 1865, had engaged a large share of his time for three years before.

While mainly occupied in those years with philosophical studies, Mill did not remit his interest in current politics. He supported the North in the American crisis of 1862, using all his strength to explain what has since been universally recognized as the issue really at stake in the struggle, the abolition of slavery. It was characteristic of the closeness with which he watched current events, and of his zeal in the cause of "lucidity," that when the *Reader*, an organ of science and unpartisan opinion, fell into difficulties in 1865 Mill joined with some distinguished men of science and letters in an effort to keep it afloat. He supplied part of the money for carrying it on, contributed several articles, and assisted the editor, Fraser Rae, with his advice. The effort was vain, though such men as Herbert Spencer, Huxley, Tyndall, Cairnes, Mark Pattison, F. Harrison, Sir Frederick Pollock and Lockyer were among the contributors.

In 1865 he agreed to stand as parliamentary candidate for Westminster, on conditions strictly in accordance with his principles. He would not canvass, nor pay agents to canvass for him, nor would he engage to attend to the local business of the constituency. He was with difficulty persuaded even to address a meeting of the electors. The story of this remarkable election has been told by James Beal, one of the most active supporters of Mill's candidature. In parliament he adhered to his life-long principle of doing only work that needed to be done, and that nobody else seemed equally able or willing to do. It may have been a consciousness of this fact which prompted a remark, made by the Speaker, that Mill's presence in parliament elevated the tone of debate. The impression made by him in parliament is in some danger of being forgotten, because he was not instrumental in carrying any great measure that might serve as an abiding memorial. But, although his first speech on the bill for the prevention of cattle diseases excited the opposition of country members, and a subsequent speech against the suspension of the Habeas Corpus Act in Ireland was very unfavourably received, Mill thoroughly succeeded in gaining the ear of the House. The only speech made by him during his three years in parliament that was listened to with impatience was, curiously enough, his speech in favour of counteracting democracy by providing for the representation of minorities. His attack on the conduct of Governor Eyre in Jamaica (*q.v.*) was listened to, but with repugnance by the majority, although his action in this matter in and out of parliament was far from being ineffectual. He took an active part in the debates on Disraeli's Reform Bill (moving an amendment to omit the word "man" and insert "person"), and helped to extort from the government several useful modifications of the Bill for the Prevention of Corrupt Practices. The reform of land tenure in Ireland, the representation of women, the reduction of the national debt, the reform of London government, the abrogation of the Declaration of Paris, were among the topics on which he spoke with marked effect. He took occasion more than once to enforce what he had often advocated in writing, England's duty to intervene in foreign politics in support of the cause of freedom. As a speaker Mill was somewhat hesitating, pausing occasionally as if to recover the thread of his argument, but he showed great readiness in extemporaneous debate. Viewed as a candidate for ministerial office, he might be regarded as a failure in parliament, but there can be no doubt that his career there greatly extended his influence.

Mill's subscription to the election expenses of Bradlaugh, and his attitude towards Governor Eyre, are generally regarded as the main causes of his defeat in the general election of 1868. But, as he suggests himself, his studied advocacy of unfamiliar projects of reform had made him unpopular with "moderate Liberals." He retired with a sense of relief to his cottage and his literary life at Avignon. His parliamentary duties and the quantity of correspondence brought upon him by increased publicity had absorbed nearly the whole of his time. The scanty leisure of his first recess had been devoted to writing his St Andrews rectorial address on higher education and to answering attacks on his criticism of Hamilton; of the second, to annotating in conjunction with Bain and Findlater, his father's *Analysis of the Mind*. Now he looked forward to a literary life, and his letters show how much he enjoyed the change. His little cottage was filled with books and newspapers; the beautiful country round it furnished him with a variety of walks; he read, wrote, discussed, walked, botanized. He was extremely fond of music, and was himself a fair pianist. His step-daughter, Miss Taylor (d. January 1907), was his constant companion after his wife's death. "Helen," he wrote to W. T. Thornton, an old colleague in the India House, "has carried out her long-cherished scheme (about which she tells me she consulted you) of a 'vibratory' for me, and has made a pleasant covered walk, some 30 ft. long, where I can vibrate in cold or rainy weather. The terrace, you must know, as it goes round two sides of the house, has got itself dubbed the 'semi-circumgyratory.' In addition to this, Helen has built me a herbarium, a little room fitted up with closets for my plants, shelves for my botanical books, and a great table whereon to manipulate them all. Thus, you see, with my herbarium, my vibratory, and my semi-circumgyratory, I am in clover; and you may imagine with what scorn I think of the House of Commons, which, comfortable club as it is said to be, could offer me none of these comforts, or, more perfectly speaking, these necessaries of life." Mill was an enthusiastic botanist all his life long, and a frequent contributor of notes and short papers to the *Phytologist*. One of the things that he looked forward to during his last journey to Avignon was seeing the spring flowers and completing a flora of the locality. His delight in scenery frequently appears in letters written to his friends during his summer and autumn tours.

---

[1] He was one of the founders, with Mrs P. A. Taylor, Miss Emily Davies and others, of the first women's suffrage society, which developed into the National Union of Women's Suffrage Societies, and his writings are still the most important theoretical statement of the case for women's suffrage. He presented to Parliament the first petition on the subject (see further Blackburn, *Women's Suffrage Record*).

Yet he did not relax his laborious habits nor his ardent outlook on human affairs. The essays in the fourth volume of his *Dissertations*—on endowments, on land, on labour, on metaphysical and psychological questions—were written for the *Fortnightly Review* at intervals after his short parliamentary career. One of his first tasks was to send his treatise on the *Subjection of Women* (written 1861, published 1869, many editions) through the press. The essay on *Theism* was written soon after. The last public work in which he engaged was the starting of the Land Tenure Reform Association. The interception by the state of the unearned increment, and the promotion of co-operative agriculture, were the most striking features in his programme. He wrote in the *Examiner* and made a public speech in favour of the association a few months before his death. The secret of the ardour with which he took up this question probably was his conviction that a great struggle was impending in Europe between labour and capital. He regarded his project as a timely compromise.

Mill died at Avignon on the 8th of May 1873. He was a man of extreme simplicity in his method of life. Though occasionally irritable in speech, in his written polemics he was remarkable for courtesy to opponents and a capacity to understand their point of view. His references to his friends were always generous, and he was always ready to assist those whose work needed help. For example, he desired to guarantee the cost of the first books of Bain and Herbert Spencer. A statue in bronze was placed on the Thames Embankment, and there is a good portrait by Watts (a copy of which, by Watts himself, was hung in the National Gallery).

The influence which Mill's works exercised upon contemporary English thought can scarcely be overestimated. His own writings and those of his successors (*e.g.* J. E. Cairnes and Alexander Bain) practically held the field during the third quarter of the 19th century and even later. In philosophy his chief work was to systematize and expound the utilitarianism of his father and Bentham (see Utilitarianism). He may, in fact, be regarded as the final exponent of that empirical school of philosophy which owed its impulse to John Locke, and is generally spoken of as being typically English. Its fundamental characteristic is the emphasis laid upon human reason, *i.e.* upon the duty incumbent upon all thinkers to investigate for themselves rather than to accept the authority of others. Knowledge must be based upon experience. In reasserting and amplifying the empirical conclusions of his predecessors, especially in the sphere of ethics, Mill's chief function was the introduction of the humanist element. This was due, no doubt, to his revulsion from the sternness of his upbringing and the period of stress through which he passed in early manhood, but also to the sympathetic and emotional qualities which manifested themselves in his early manhood. We have seen, for example, that he was led to investigate the subject of logic because he found in attempting to advance his humanitarian schemes in politics an absence of that fundamental agreement which he recognized as the basis of scientific advance. Both his logical and his metaphysical studies were thus undertaken as the pre-requisites of a practical theory of human development. Though he believed that the lower classes were not yet ripe for socialism, with the principles of which he (unlike James Mill and Bentham) was in general agreement, his whole life was devoted to the amelioration of the conditions of the working classes. This fact, no doubt, should be taken into account in any detailed criticism of the philosophic work; it was taken up not as an end but as ancillary to a social and ethical system. Reference to the articles on Logic, Metaphysics, &c., will show that subsequent criticism, however much it has owed by way of stimulus to Mill's strenuous rationalism, has been able to point to much that is inconsistent, inadequate and even superficial in his writings. Two main intellectual movements from widely different standpoints have combined to diminish his influence. On the one hand there has arisen a school of thinkers of the type of Thomas Hill Green, who have brought to bear on his metaphysical views the idealism of modern German thinkers. On the other hand are the evolutionists, who have substituted for the utilitarian ideal of the "greatest happiness" those of "race-preservation" and the "survival of the fittest" (see Ethics, *ad. fin.*; Spencer). In the sphere of psychology, likewise—*e.g.* in connexion with Mill's doctrine of Association of Ideas (*q.v.*) and the phrase "Mental Chemistry," by which he sought to meet the problems which Associationism left unsolved—modern criticism and the experimental methods of the psycho-physiological school have set up wholly new criteria, with a new terminology and different fields of investigation (see Psychology).

A similar fate has befallen Mill's economic theories. The title of his work, *Principles of Political Economy, with some of their Applications to Social Philosophy*, though open to criticism, indicated a less narrow and formal conception of the field of the science than had been common amongst his predecessors. He aimed in fact at producing a work which might replace in ordinary use the *Wealth of Nations*, which in his opinion was "in many parts obsolete and in all imperfect." Adam Smith had invariably associated the general principles of the subject with their applications, and in treating those applications had perpetually appealed to other and often far larger considerations than pure political economy affords. And in the same spirit Mill desired, whilst incorporating all the results arrived at in the special science by Smith's successors, to exhibit purely economic phenomena in relation to the most advanced conceptions of his own time in the general philosophy of society, as Smith had done in reference to the philosophy of his century. This design he certainly failed to realize. His book is very far indeed from being a "modern Adam Smith." It is an admirably lucid, and even elegant, exposition of the Ricardian economics, the Malthusian theory being of course incorporated with these; but, notwithstanding the introduction of many minor novelties, it is in its scientific substance little or nothing more.

With respect to economic method he shifted his position, yet to the end occupied uncertain ground. In the fifth of his early essays he asserted that the method a priori is the only mode of investigation in the social sciences, and that the method a posteriori "is altogether inefficacious in those sciences as a means of arriving at any considerable body of valuable truth." When he wrote his *Logic* he had learned from Comte that the a posteriori method—in the form which he chose to call "inverse deduction"—was the only mode of arriving at truth in general sociology; and his admission of this at once renders the essay obsolete. But, unwilling to relinquish the a priori method of his youth, he tries to establish a distinction of two sorts of economic inquiry, one of which, though not the other, can be handled by that method. Sometimes he speaks of political economy as a department "carved out of the general body of the science of society;" whilst on the other hand the title of his systematic work implies a doubt whether political economy is a part of "social philosophy" at all, and not rather a study preparatory and auxiliary to it. Thus, on the logical as well as the dogmatic side, he halts between two opinions. Notwithstanding his misgivings and even disclaimers, he yet remained as to method a member of the old school, and never passed into the new "historical" school.

Bibliography.—*Works: System of Logic* (2 vols., 1843; 9th ed., 1875; "People's" ed., 1884); *Essays on some Unsettled Questions of Political Economy* (1844, ed. 1874); *Principles of Political Economy* (2 vols., 1848; many ed., especially ed. by W. J. Ashley, 1909); *On Liberty* (1859; ed. Courtney, 1892; W. B. Columbine, 1903; with introd. Pringle-Pattison, 1910); *Thoughts on Parliamentary Reform* (1859); *Dissertations and Discussions* (i., ii., 1859; iii., 1867; iv., 1876); *Considerations on Representative Government* (1861; 3rd ed. 1865); *Utilitarianism* (1863); *Examination of Sir W. Hamilton's Philosophy* (1865); *Aug. Comte and Positivism* (1865, ed. 1908); *Inaugural Address at the University of St Andrews* (1867); *England and Ireland* (1868); *Subjection of Women* (1869; ed. with introd. by Stanton Coit, 1906); *Chapters and Speeches on the Irish Land Question* (1870). The *Autobiography* appeared in 1873 (ed. 1908), and *Three Essays on Religion* (1874). Many of these have been translated into German, and there is a German edition by Th. Gomperz (12 vols., 1873–1880). A convenient edition in the New Universal Library appeared between 1905 and 1910.

Biographical and Critical.—Many of Mill's letters are published in Mrs Grote's life of her husband, in Duncan's *Life of Herbert Spencer*, in the *Memories* of Caroline Fox, and in Kingsley's letters. There are also editions of the correspondence with Gustave d'Eichtal and Comte (specially that of Lévy-Bruhl, 1899). By far the most illuminating collection is that of Hugh Elliott, *Letters of John Stuart Mill* (2 vols., 1910), which contains letters to John Sterling, Carlyle, E. Lytton Bulwer (Lord Lytton), John Austin, Alex. Bain, and many leading French and German writers and politicians. These letters are essential to an understanding of Mill's life and thought. Besides the *Autobiography* and many references in the writings of Mill's friends (*e.g.* Alex. Bain's *Autobiography*, 1904), see further

A. Bain, *John Stuart Mill, a Personal Criticism* (1882); Fox Bourne, *Life of J. S. Mill* (1873); John (Viscount) Morley, *Miscellanies* (1877), ii. 239–327; J. E. Cairnes, *J. S. Mill* (1873), on economic theories; W. L. Courtney, *Mataphysics of J. S. Mill* (1879) and *Life* (1889); Douglas, *John Stuart Mill, a Study of his Philosophy* (1895), and *Ethics of J. S. Mill* (1897); Albee, *Hist. of Eng. Utilitarianism* (1902); Sir Leslie Stephen, *The English Utilitarians* (1900); J. MacCunn, *Six Radical Thinkers* (1907); Fred. Harrison, *Tennyson, Ruskin, Mill* (1899); John Watson, *Comte, Mill and Spencer* (1895); T. Whittaker, *Comte and Mill* (1905); Charles Douglas, *J. S. Mill, a Study of his Philosophy* (1895); J. Rickaby, *Free Will and Four English Philosophers* (1906); J. M. Robertson, *Modern Humanists* (1891); D. G. Ritchie, *Principles of State Interference* (1891); W. Graham, *English Political Philosophy from Hobbes to Maine* (1899). There are also a number of valuable French and German criticisms, *e.g.* Taine, *Positivisme anglais, étude sur Stuart Mill* (Paris, 1864); F. A. Lange, *Mills Ansichten über die soziale Frage* (Duisburg, 1866); Littré, *A. Çomte et Stuart Mill* (3rd ed., Paris, 1877); Cauret, *Philosophie de Stuart Mill* (Paris, 1885); Gomperz, *John S. Mill, ein Nachruf* (Vienna, 1889); S. Sanger, *J. S. Mill, sein Leben und Lebenswerk* (Stuttgart, 1901); S. Becher, *Erkenntnistheoretische Untersuchungen zu Stuart Mills Theorie der Kausalität* (1906); E. M. Kantzer, *La Religion de J. S. Mill* (1906). See also histories of modern philosophy.

See further LOGIC (Historical Sketch); PSYCHOLOGY; ASSOCIATION OF IDEAS. (W. M.; J. M. M.)

MILL (O. Eng. *mylen*, later *myln*, or *miln*, adapted from the late Lat. *molina*, cf. Fr. *moulin*, from Lat. *mola*, a mill, *molere*, to grind; from the same root, *mol*, is derived " meal;" the word appears in other Teutonic languages, cf. Du. *molen*, Ger. *mühle*), the term given to the apparatus or machinery used in the grinding of corn into flour, and hence applied to similar mechanical devices for grinding, crushing to powder, or pulping other substances, *e.g.* coffee-mill, powder-mill. " Mill " was first used of the building containing the apparatus, frequently with a word attached descriptive of the motive power, *e.g.* wind-mill, water-mill, &c. It was not the early word used of the actual grinding mechanism. The old hand-mill was known as a " quern," a word which appears in this sense in many Indo-European languages; the ultimate root is *gar-*, to grind. " Quern " (see FLOUR) is only remotely connected with " churn " (*q.v.*). The word is also applied to many mechanical devices by which raw material is transformed into a condition ready for use or into a stage preparatory to other processes, *e.g.* saw-mill, rolling-mill, &c., or still more widely to buildings containing machinery used in manufactures, *e.g.* cotton-mill. In mining it is applied to various machines used in breaking and crushing the ore (see ORE-DRESSING).

In the engineering industries milling machines constitute a very important class of machine tools, the characteristic of which is that rotary cutters are employed for shaping the metal (see TOOLS). In coins the " milling is the serrated edge, called " crenneling " by John Evelyn (*Discourse on Medals*, 1697, p. 225), which is formed on them to prevent clipping and filing. Coins made by the old process of hammering were apt to have irregular edges which invited mutilation; but the introduction of the screw press, which came to be known as a mill (cf. W. Lowndes, *Amendm. Silver Coinage*, 1695, p. 93), permitted the production of a regular edge with serrations, which in consequence were termed milling. This machine also enabled legends to be impressed round the edges of coins, such as the *Decus et tutamen* suggested by Evelyn (see W. J. Hocking, *Catalogue of the Coins, &c., in the Museum of the Royal Mint*, 1906). It was invented about the middle of the 16th century, and has generally been attributed to Guyot Brucher (d. 1556), who was succeeded at the Paris mint by his brother Antoine. Introduced into England by one Eloye Mestrel in 1561, it was used for twelve years, and was then abandoned owing to the opposition of the mint officials to Mestrel, who was executed for counterfeiting and striking money outside the precincts of the Tower of London; but it was again introduced by one Peter Blondeau in 1662, when it permanently superseded hammering. In the United States of America the term " milling " or " milled " is applied to the raised edge on the face of the coin; this is known in the British mint as " marking " (see MINT).

MILLAIS, SIR JOHN EVERETT (1829–1896), English painter, was born at Southampton on the 8th of June 1829, the son of John William Millais, who belonged to an old Norman family settled in Jersey for many generations, and Emily Mary, *née* Evamy, the widow of a Mr Hodgkinson. After his birth the family returned to Jersey, where the boy soon began to sketch. At the age of eight he drew his maternal grandfather. He went to school for a short time, but showed no inclination for study, and was afterwards educated entirely by his mother. In 1835 the family removed to Dinan in Brittany, where he sketched the French officers, to their great amusement, and in 1837, on the family's return to Jersey, he was taught drawing by a Mr Bissel. In 1838 he came to London, and on the strong recommendation of Sir Martin Archer Shee, P.R.A., his future was decided. He was sent at once to Sass's school, and entered the Academy schools in 1840. He won a silver medal from the Society of Arts in 1839, and carried off all the prizes at the Royal Academy. He was popular amongst the students, and was called " the child," because he wore his boyish costume till long after the usual age. In 1840 and the immediately succeeding years he made the acquaintance of Wordsworth and other interesting and useful people. He was at this time painting small pictures, &c., for a dealer named Thomas, and defraying a great part of the household expenses in Gower Street, where his family lived. In 1846 he exhibited " Pizarro seizing the Inca of Peru " at the Royal Academy, and in 1847 " Elgiva seized by the Soldiers of Odo." In the latter year he competed unsuccessfully at the exhibition of designs for the decoration of the Houses of Parliament, sending a very large picture of " The Widow's Mite," which was afterwards cut up. In the beginning of 1848 he and W. Holman Hunt, dissatisfied with the theory and practice of British art, which had sunk to its lowest and most conventional level, initiated what is known as the Pre-Raphaelite movement, and were joined by Dante Gabriel Rossetti, and afterwards by five others, altogether forming the Pre-Raphaelite Brotherhood. Rossetti was then engaged, under the technical guidance of Hunt, upon his picture of " The Girlhood of Mary Virgin," which, with Hunt's " Light of the World " and Millais's " Christ in the House of His Parents," forms what has been called the trilogy of Pre-Raphaelite art. According to Millais, the Pre-Raphaelites had but one idea—" to present on canvas what they saw in Nature." Millais's first picture on his new principles was a banquet scene from Keats's " Isabella " (1849), and contains all the characteristics of Pre-Raphaelite work, including minute imitation of nature down to the smallest detail, and the study of all persons and objects directly from the originals. The tale was told with dramatic force, and the expression of the heads was excellent. His next important picture, " Christ in the House of His Parents," or " The Carpenter's Shop " (1850), represented a supposed incident in the childhood of our Lord treated in a simply realistic manner, and drew down upon him a storm of abuse from nearly all quarters, religious and artistic. The rest of his more strictly Pre-Raphaelite pictures—" The Return of the Dove to the Ark," " The Woodman's Daughter " and the " Mariana " of 1851, " The Huguenot " and " Ophelia " of 1852, " The Proscribed Royalist " and " The Order of Release " of 1853—met with less opposition, and established his reputation with the public. Indeed, this may be said to have been accomplished by the " Huguenot " and " Ophelia," the refined sentiment and exquisite execution of which appealed to nearly all who were unprejudiced. The public were also greatly influenced by the splendid championship of Ruskin, who, in letters to *The Times*, and in a pamphlet called " Pre-Raphaelitism," enthusiastically espoused the cause of the Brotherhood. In 1851 Millais, who had refused to read *Modern Painters*, where the supposed principles of the Brotherhood were first recommended, became acquainted with Ruskin, and in 1853 went to Scotland with him and Mrs Ruskin, the latter of whom sat for the woman in " The Order of Release." He made several designs for Ruskin, and painted his portrait. In 1855 Millais exhibited " The Rescue," a scene from a fire, which drew great attention, from the frantic expression of the mother and the brilliant painting of the glare. In the Paris Exhibition of this year he was represented by " The Order of Release," " Ophelia " and " The Return of the Dove." This was also the year of his marriage with Mrs Ruskin (Euphemia Chalmers, daughter of Mr George Gray of Bowerswell, Perth), who had obtained a decree of the nullity of her previous marriage. The newly-wedded couple went to live at Annat Lodge, near Bowerswell, where "Autumn Leaves," described by Ruskin as "the first instance of a perfect twilight," was painted. This and "Peace Concluded" were singled out for special praise by Ruskin in his notes on the Academy Exhibition of 1856, which contained, with other works by Millais, the picture of "A Blind Girl," with a beautiful background of Icklesham and its common. The principal pictures of 1857 were "Sir Isumbras at the Ford," and "The Escape of a Heretic," both of which were violently attacked by Ruskin, who was kinder to the "Apple-blossoms" and "Vale of Rest" of 1859, extolling the power of their painting, but still insisting on the degeneracy of the artist. The "Black Brunswicker" of 1860 was in motive very like the "Huguenot," but it was less refined in expression, and a great deal broader in execution, and may be said to mark the end of the period of transition from his minute Pre-Raphaelite manner to the masterly freedom of his mature style. From 1860 to 1869 the invention of Millais was much employed in illustration, especially of Trollope's novels, beginning with *Framley Parsonage* in the *Cornhill Magazine*. He made altogether eighty-seven drawings for Trollope, and was the cleverest and one of the most prolific of the book illustrators of the 'sixties. He contributed to Moxon's illustrated edition of *Tennyson's Poems*, and made occasional drawings for *Once a Week*, the *Illustrated London News*, *Good Words*, and other periodicals and books. In 1863 he was elected a Royal Academician. The most important pictures of this and the next few years were "The Eve of St Agnes," remarkable for the painting of moonlight, "Romans leaving Britain" (1865), "Jephthah" (1867), "Rosalind and Celia" (1868), "A Flood," and "The Boyhood of Raleigh" (1870). All these were executed in a very broad and masterly manner. In many of his pictures of this period, such as "The Boyhood of Raleigh," his children were his models, and formed the subject of many more, like "My First Sermon," "My Second Sermon," "Sleeping," "Awake," "Sisters," "The First Minuet," and "The Wolf's Den." He now painted many single figures with more or less sentiment, like "Stella," "Vanessa," and "The Gambler's Wife," with occasionally a more important composition, like "Pilgrims to St Paul's," and "Victory, O Lord" (exhibited 1871), representing Aaron and Hur holding up Moses' hands (Exod. xvii. 12). With it was exhibited the first and most popular of his pure landscapes, called "Chill October," which was followed at intervals by several others remarkable for literal truth to nature and fine execution. They were all from Perthshire, where he generally spent the autumn, and included "Scotch Firs" and "Winter Fuel" (painted in 1874), "Over the Hills and Far away," and "The Fringe of the Moor" (1875) and "The Sound of Many Waters" (1876). A later series was painted in the neighbourhood of Murthly, a village in the parish of Little Dunkeld, Perthshire, where he rented a house and shooting from 1881 to 1891. It was to painting nature and the world around him that he principally devoted himself for the last twenty-five years of his life, abandoning imaginative or didactic themes. To this period belong a number of pictures of children, with fancy titles, like "Cherry Ripe," "Little Miss Muffet," "Bubbles," and others well known by reproductions in black and white and in colour for the illustrated papers; and also some charming studies of girlhood, like "Sweetest eyes were ever seen," and "Cinderella." Amongst his more serious pictures were "The Princes in the Tower" (1878), "The Princess Elizabeth" (1879), two pictures from Scott—"Effie Deans" and "The Master of Ravenswood"—painted for Messrs Agnew in 1877 and 1878, and "The North-West Passage," sometimes regarded as his masterpiece, representing an old mariner (painted from Edward John Trelawney, the friend of Byron) listening to some tale of Arctic exploration in a room overlooking the sea and strewn with charts. "A Yeoman of the Guard" (1877) was perhaps his most splendid piece of colour, and was greatly admired at the Paris Exhibition of 1878, where it was sent with "Chill October" and three others of his pictures. But perhaps the works of his later years by which he will be most remembered are his portraits—especially his three portraits of Gladstone (1879, 1885 and 1890), and those of John Bright, of Lord Tennyson, and of Lord Beaconsfield, which was left unfinished at his death. He also painted the marquess of Salisbury, Lord Rosebery, the dukes of Devonshire and Argyll, Cardinal Newman, Thomas Carlyle, Sir James Paget, Sir Henry Irving, George Grote, Lord Chief Justice Russell, J. C. Hook, R.A., and himself (Uffizi Gallery, Florence). He drew Charles Dickens after his death. Amongst his finer portraits of women were those of Mrs Bischoffsheim, the duchess of Westminster, Lady Campbell and Mrs Jopling.

No very serious interruption of his usual life as a prosperous English gentleman occurred in these years, except the death of his second son, George, in 1878. In 1875 he went to Holland, one of his few visits to the Continent. In 1879 he left Cromwell Place for a house at Palace Gate, Kensington, which he built, and where he died. In 1885 he was created a baronet, on the suggestion of Mr Gladstone. In 1892 his health began to break down. After a bad attack of influenza he was troubled with a swelling in his throat, which proved to be due to cancer. He suffered much from depression, but worked when he could, and derived much pleasure in painting several pictures, including "St Stephen," "A Disciple," "Speak! Speak!" (which was bought out of the Chantrey Bequest), and "The Forerunner"—his last exhibited subject-picture. His finely-characterized portraits of Mr John Hare, the actor, and Sir Richard Quain belong also to his last years. In 1895, in consequence of the illness of Lord (then Sir Frederick) Leighton, he was called upon to preside at the annual banquet of the Royal Academy, and on the death of Lord Leighton he was elected to the presidential chair. He died on the 13th of August 1896, and was buried in St Paul's Cathedral. The Winter Exhibition of the Royal Academy in 1898 was devoted to his works. The list of his honours at home and abroad is a long one. Millais was one of the greatest painters of his time, and did more than any other to infuse a new and healthy life into British art. He had not the imagination of an idealist, but he could paint what he saw with a force which has seldom been excelled. As a man he was manly, frank and genial, devoted to his art and his family, and very fond of sport, especially hunting, fishing and shooting. He was greatly loved by a very large circle of friends. He was singularly handsome, and had a fine presence. The National Gallery of British Art possesses many of his finest works. He is also represented in the National Gallery, in the National Portrait Gallery, the Victoria and Albert Museum, and in the public galleries at Manchester, Liverpool and Birmingham.

MILLAR, ANDREW (1707–1768), British publisher, was born in 1707. About 1729 he started business as a bookseller and publisher in the Strand, London. His own judgment in literary matters was small, but he collected an excellent staff of literary advisers, and did not hesitate to pay what at the time were considered large prices for good material. "I respect Millar, sir," said Dr Johnson in 1755, "he has raised the price of literature." He paid Thomson £105 for *The Seasons*, and Fielding a total sum of £700 for *Tom Jones* and £1000 for *Amelia*. He was one of the syndicate of booksellers who financed Johnson's *Dictionary*, and on him the work of seeing that book through the press mainly fell. He also published the histories of Robertson and Hume. He died at his villa at Kew Green, near London, on the 8th of June 1768.

MILLAU, a town of southern France, capital of an arrondissement in the department of Aveyron, on the right bank of the Tarn at its confluence with the Dourbie, 74 m. N. of Béziers on the Southern railway. Pop. (1906), 16,853. Millau lies in a rich valley 1200 ft. above the sea surrounded by the spurs of the Levezou, Causse Noir and Larzac ranges. The streets are narrow and some of the houses of great antiquity, but the town is surrounded by spacious boulevards. One of its squares is bordered on two sides by wooden galleries supported on stone columns. The only buildings of special interest are the Romanesque church of Notre Dame, restored in the 16th century, and the fine Gothic belfry of the old hôtel de ville. Millau is seat of a sub-prefect, and possesses tribunals of first instance and of commerce, a board of trade-arbitrators, a chamber of commerce and a communal college. The principal industry is the manufacture of gloves, and various branches of the leather industry are carried on. The chief articles of trade are skins, wool, wine and Roquefort cheese.

In the middle ages Millau was the seat of a viscounty held by the counts of Barcelona and afterwards by the counts of Armagnac. In the 16th century it became one of the leading strongholds of Calvinism in southern France. In 1620 it revolted against Louis XIII., and after its submission Richelieu caused its fortifications to be dismantled. The edict of Nantes hastened the decline of the town, which did not recover its prosperity till after the Revolution.

MILLBURY, a township of Worcester county, Massachusetts, on the Blackstone river, 5 m. S.S.E. of Worcester. Pop. (1890), 4428; (1900) 4460 (1176 foreign-born); (1905, state census) 4631; (1910) 4740. Area, 15·79 sq. m. Millbury is served by the New York, New Haven & Hartford, and the Boston & Albany railways, and by electric interurban railways. It lies for the most part in the valley of the Blackstone river, from which water-power is derived for its mills; among its manufactures are cotton, linen, felt and woollen goods, hemp thread, and foundry and machine-shop products. The municipality owns and operates the waterworks and electric-lighting plant. Millbury was formed in 1813 from the North Parish of Sutton; in 1851 a part of Auburn was annexed to the township.

MILLEDGEVILLE, a city and the county-seat of Baldwin county, in the central part of Georgia, U.S.A., on the Oconee river, at the head of navigation, 32 m. E.N.E. of Macon. Pop. (1890), 3322; (1900), 4219 (2663 negroes); (1910), 4385. It is served by the Georgia and the Central of Georgia railways. Milledgeville is situated in the Cotton Belt, and its principal industry is the preparation of cotton for the markets. The importance of the place, however, is mainly educational and historical. It is the seat of the Middle Georgia Military and Agricultural College, which occupies the old capitol building, and of the Georgia Normal and Industrial College for girls (1889; enrolment 1908–1909, 653), which is a part of the University of Georgia, and occupies the site of the old state penitentiary. About 2 m. north-west of Milledgeville is the state juvenile reformatory; 2 m. south of the city are the state asylums for white and negro insane; and 3 m. north-west is the state prison farm. Milledgeville was founded in 1803, and was named in honour of John Milledge (1757–1818), a representative in Congress in 1792–1793 and 1795–1802, governor of Georgia in 1802–1806, a United States senator in 1806–1809, and a benefactor of the state university. In 1804 it was made the seat of the state government in place of Louisville (capital in 1795–1804; pop. in 1900, 1009), a dignity it held until 1868. The city was first chartered in 1836. Although admirably situated for trade and manufacturing, Milledgeville was surpassed in both by Macon, which became the commercial emporium of middle Georgia; but it was a favourite place of residence for the wealthy and cultivated class of Georgians before the Civil War. It was seized by General William T. Sherman on the 23rd of November 1864. In order to remove the state documents beyond reach of the enemy, Governor Joseph E. Brown called upon the convicts in the penitentiary for aid, granting them pardons in return for their services.

MILLENNIUM (a pseudo-Latin word formed on the analogy of *biennium*, *triennium*, from Lat. *mille*, a thousand, and *annus*, year), literally a period of a thousand years. The term is specially used of the period of 1000 years during which Christ, as has been believed, would return to govern the earth in person. Hence it is used to describe a vague time in the future when all flaws in human existence will have vanished, and perfect goodness and happiness will prevail. The attribution of a mystic significance to the millennium-period, though perhaps not prominent in that theory of Christian eschatology to which the names Millenarianism and Chiliasm (from Gr. χιλιάς, a thousand) are given, is quite common in non-Christian religions and cosmological systems.

Faith in the nearness of Christ's second advent and the establishing of his reign of glory on the earth was undoubtedly a strong point in the primitive Christian Church. In the anticipations of the future prevalent amongst the early Christians (*c.* 50–150) it is necessary to distinguish a fixed and a fluctuating element. The former includes (1) the notion that a last terrible battle with the enemies of God was impending; (2) the faith in the speedy return of Christ; (3) the conviction that Christ will judge all men, and (4) will set up a kingdom of glory on earth. To the latter belong views of the Antichrist, of the heathen world-power, of the place, extent, and duration of the earthly kingdom of Christ, &c. These remained in a state of solution; they were modified from day to day, partly because of the changing circumstances of the present by which forecasts of the future were regulated, partly because the indications—real or supposed—of the ancient prophets always admitted of new combinations and constructions. But even here certain positions were agreed on in large sections of Christendom. Amongst these was the expectation that the future kingdom of Christ on earth should have a fixed duration—according to the most prevalent opinion, a duration of one thousand years. From this fact the whole ancient Christian eschatology was known in later times as "chiliasm"—a name which is not strictly accurate, since the doctrine of the millennium was only one feature in its scheme of the future.

1. This idea that the Messianic kingdom of the future on earth should have a definite duration has—like the whole eschatology of the primitive Church—its roots in the Jewish apocalyptic literature, where it appears at a comparatively late period. At first it was assumed that the Messianic kingdom in Palestine would last for ever (so the prophets; cf. Jer. xxiv. 6; Ezek. xxxvii. 25; Joel iv. 20; Dan. vi. 27; Sibyll. iii. 49 seq., 766; Psalt. Salom. xvii. 4; Enoch lxii. 14), and this seems always to have been the most widely accepted view (John xii. 34). But from a comparison of prophetic passages of the Old Testament learned apocalyptic writers came to the conclusion that a distinction must be drawn between the earthly appearance of the Messiah and the appearance of God Himself amongst His people and in the Gentile world for the final judgment. As a necessary consequence, a limited period had to be assigned to the Messianic kingdom. According to the Apocalypse of Baruch (xl. 3) this kingdom will last "donec finiatur mundus corruptionis." In the Book of Enoch (xci. 12) "a week" is specified, in the Apocalypse of Ezra (vii. 28 seq.) four hundred years. This figure, corresponding to the four hundred years of Egyptian bondage, occurs also in the Talmud (Sanhedrin 99*a*). But this is the only passage; the Talmud has no fixed doctrine on the point. The view most frequently expressed there (see Von Otto in *Hilgenfeld's Zeitschrift*, 1877, p. 527 seq.) is that the Messianic kingdom will last for one thousand (some said two thousand) years. "In six days God created the world, on the seventh He rested. But a day of God is equal to a thousand years (Ps. xc. 4). Hence the world will last for six thousand years of toil and labour; then will come one thousand years of Sabbath rest for the people of God in the kingdom of the Messiah." This idea must have already been very common in the first century before Christ. The combination of Gen. i., Dan. ix. and Ps. xc. 4 was peculiarly fascinating.

Nowhere in the discourses of Jesus is there a hint of a limited duration of the Messianic kingdom. The apostolic epistles are equally free from any trace of chiliasm (neither 1 Cor. xv. 23 seq. nor 1 Thess. iv. 16 seq. points in this direction). In Revelation however, it occurs in the following shape (ch. xx.). After

Christ has appeared from heaven in the guise of a warrior, and vanquished the antichristian world-power, the wisdom of the world and the devil, those who have remained steadfast in the time of the last catastrophe, and have given up their lives for their faith, shall be raised up, and shall reign with Christ on this earth as a royal priesthood for one thousand years. At the end of this time Satan is to be let loose again for a short season; he will prepare a new onslaught, but God will miraculously destroy him and his hosts. Then will follow the general resurrection of the dead, the last judgment, and the creation of new heavens and a new earth. That *all* believers will have a share in the first resurrection and in the Messianic kingdom is an idea of which the author of Revelation knows nothing. The earthly kingdom of Christ is reserved for those who have endured the most terrible tribulation, who have withstood the supreme effort of the world-power—that is, for those who are actually members of the church of the last days. The Jewish expectation is thus considerably curtailed, as it is also shorn of its sensual attractions. "Blessed and holy is he that hath part in the first resurrection; on such the second death hath no power; but they shall be priests of God and of Christ, and shall reign with Him a thousand years." Other ancient Christian authors were not so cautious. Accepting the Jewish apocalypses as sacred books of venerable antiquity, they read them eagerly, and transferred their contents bodily to Christianity. Nay more, the Gentile Christians took possession of them, and just in proportion as they were neglected by the Jews—who, after the war of Bar-Cochba, became indifferent to the Messianic hope and hardened themselves once more in devotion to the law—they were naturalized in the Christian communities. The result was that these books became "Christian" documents; it is entirely to Christian, not to Jewish, tradition that we owe their preservation. The Jewish expectations are adopted for example, by Papias, by the writer of the epistle of Barnabas, and by Justin. Papias actually confounds expressions of Jesus with verses from the Apocalypse of Baruch, referring to the amazing fertility of the days of the Messianic kingdom (Papias in Iren. v. 33). Barnabas (*Ep.* 15) gives us the Jewish theory (from Gen. i. and Ps. xc. 4) that the present condition of the world is to last six thousand years from the creation, that at the beginning of the Sabbath (the seventh millennium) the Son of God appears, to put an end to the time of "the unjust one," to judge the ungodly and renew the earth. But he does not indulge, like Papias, in sensuous descriptions of this seventh millennium; to Barnabas it is a time of rest, of sinlessness, and of a holy peace. It is not the end, however; it is followed by an eighth day of eternal duration—"the beginning of another world." So that in the view of Barnabas the Messianic reign still belongs to *οὗτος ὁ αἰών*. Justin (*Dial.* 80) speaks of chiliasm as a necessary part of complete orthodoxy, although he knows Christians who do not accept it. He believes, with the Jews, in a restoration and extension of the city of Jerusalem; he assumes that this city will be the seat of the Messianic kingdom, and he takes it as a matter of course that there all believers (here he is at one with Barnabas) along with patriarchs and prophets will enjoy perfect felicity for one thousand years. That a philosopher like Justin, with a bias towards an Hellenic construction of the Christian religion, should nevertheless have accepted its chiliastic elements is the strongest proof that these enthusiastic expectations were inseparably bound up with the Christian faith down to the middle of the 2nd century. And another proof is found in the fact that even a speculative Jewish Christian like Cerinthus not only did not renounce the chiliastic hope, but pictured the future kingdom of Christ as a kingdom of sensual pleasures, of eating and drinking and marriage festivities (Euseb. *H. E.* iii. 28, vii. 25).

After the middle of the 2nd century these expectations were gradually thrust into the background. They would never have died out, however, had not circumstances altered, and a new mental attitude been taken up. The spirit of philosophical and theological speculation and of ethical reflection, which began to spread through the churches, did not know what to make of the old hopes of the future. To a new generation they seemed paltry, earthly and fantastic, and far-seeing men had good reason to regard them as a source of political danger. But more than this, these wild dreams about the glorious kingdom of Christ began to disturb the organization which the churches had seen fit to introduce. In the interests of self-preservation against the world, the state and the heretics, the Christian communities had formed themselves into compact societies with a definite creed and constitution, and they felt that their existence was threatened by the white heat of religious subjectivity. So early as the year 170, a church party in Asia Minor—the so-called Alogi—rejected the whole body of apocalyptic writings and denounced the book of Revelation as a book of fables. All the more powerful was the reaction. In the so-called Montanistic controversy (*c.* 160–220) one of the principal issues involved was the continuance of the chiliastic expectations in the churches. The Montanists of Asia Minor defended them in their integrity, with one slight modification: they announced that Pepuza, the city of Montanus, would be the site of the New Jerusalem and the millennial kingdom. After the Montanistic controversy chiliastic views were more and more discredited in the Greek Church; they were, in fact, stigmatized as "Jewish" and consequently "heretical." It was the Alexandrian theology that superseded them; that is to say, Neo-Platonic mysticism triumphed over the early Christian hope of the future, first among the "cultured," and then, when the theology of the "cultured" had taken the faith of the "uncultured" under its protection, amongst the latter also. About the year 260 an Egyptian bishop, Nepos, in a treatise called *ἔλεγχος ἀλληγοριστῶν*, endeavoured to overthrow the Origenistic theology and vindicate chiliasm by exegetical methods. Several congregations took his part; but ultimately Dionysius, bishop of Alexandria, succeeded in healing the schism and asserting the allegorical interpretation of the prophets as the only legitimate exegesis. During this controversy Dionysius became convinced that the victory of mystical theology over "Jewish" chiliasm would never be secure so long as the book of Revelation passed for an apostolic writing and kept its place among the homologoumena of the canon. He accordingly raised the question of its apostolic origin; and by reviving old difficulties, with ingenious arguments of his own, he carried his point. At the time of Eusebius the Greek Church was saturated with prejudice against the book and with doubts as to its canonicity. In the course of the 4th century it was removed from the Greek canon, and thus the troublesome foundation on which chiliasm might have continued to build was got rid of. The attempts of Methodius of Tyre at the beginning of the 4th century and Apollinarius of Laodicea about 360 to defend chiliasm and assail the theology of Origen had no result. For many centuries the Greek Church kept Revelation out of its canon, and consequently chiliasm remained in its grave. It was considered a sufficient safeguard against the spiritualizing eschatology of Origen and his school to have rescued the main doctrines of the creed and the *regula fidei* (the visible advent of Christ; eternal misery and hell-fire for the wicked). Anything beyond this was held to be Jewish. It was only the chronologists and historians of the church who, following Julius Africanus, made use of apocalyptic numbers in their calculations, while court theologians like Eusebius entertained the imperial table with discussions as to whether the dining-hall of the emperor—the second David and Solomon, the beloved of God—might not be the New Jerusalem of John's Apocalypse. Eusebius was not the first who dabbled in such speculations. Dionysius of Alexandria had already referred a Messianic prediction of the Old Testament to the emperor Gallienus. But mysticism and political servility between them gave the death-blow to chiliasm in the Greek Church. It never again obtained a footing there; for, although, late in the middle ages, the book of Revelation—by what means we cannot tell—did recover its authority, the Church was by that time so hopelessly trammelled by a magical cultus as to be incapable of fresh developments. In the Semitic churches of the East (the Syrian, Arabian and Ethiopian), and in that of Armenia, the apocalyptic literature was preserved much longer than in the Greek Church. They were very conservative of ancient traditions in general, and hence chiliasm survived amongst them to a later date than in Alexandria or Constantinople.

But the Western Church was also more conservative than the Greek. Her theologians had, to begin with, little turn for mystical speculation; their tendency was rather to reduce the gospel to a system of morals. Now for the moralists chiliasm had a special significance as the one distinguishing feature of the gospel, and the only thing that gave a specifically Christian character to their system. This, however, holds good of the Western theologians only after the middle of the 3rd century. The earlier fathers, Irenaeus, Hippolytus, Tertullian, believed in chiliasm simply because it was a part of the tradition of the church and because Marcion and the Gnostics would have nothing to do with it. Irenaeus (v. 28, 29) has the same conception of the millennial kingdom as Barnabas and Papias, and appeals in support of it to the testimony of disciples of the apostles. Hippolytus, although an opponent of Montanism, was nevertheless a thorough-going millennarian (see his book *De Antichristo*). Tertullian (cf. especially *Adv. Marcion.*, 3) aimed at a more spiritual conception of the millennial blessings than Papias had, but he still adhered, especially in his Montanistic period, to all the ancient anticipations. It is the same all through the 3rd and 4th centuries with those Latin theologians who escaped the influence of Greek speculation. Commodian, Victorinus Pettavensis, Lactantius and Sulpicius Severus were all pronounced millennarians, holding by the very details of the primitive Christian expectations. They still believe, as John did, in the return of Nero as the Antichrist; they still expect that after the first resurrection Christ will reign with his saints "in the flesh" for a thousand years. Once, but only once (in the Gospel of Nicodemus), the time is reduced to five hundred years. Victorinus wrote a commentary on the Apocalypse of John; and all these theologians, especially Lactantius, were diligent students of the ancient Sibylline oracles of Jewish and Christian origin, and treated them as divine revelations. As to the canonicity and apostolic authorship of the Johannine Apocalypse no doubts were ever entertained in the West; indeed an Apocalypse of Peter was still retained in the canon in the 3rd century. That of Ezra, in its Latin translation, must have been all but a canonical book—the numbers of extant manuscripts of the so-called 4 Ezra being incredibly great, while several of them are found in copies of the Latin Bible at the beginning of the 16th century. The Apocalypse of Hermas was much read till far through the middle ages, and has also kept its place in some Bibles. The apocalyptic "Testamenta duodecim patriarcharum" was a favourite reading-book; and Latin versions of ancient apocalypses are being continually brought to light from Western libraries (*e.g.* the *Assumptio Mosis*, the *Ascensio Jesajae*, &c.). All these facts show how vigorously the early hopes of the future maintained themselves in the West. In the hands of moralistic theologians, like Lactantius, they certainly assume a somewhat grotesque form, but the fact that these men clung to them is the clearest evidence that in the West millennarianism was still a point of "orthodoxy" in the 4th century.

This state of matters, however, gradually disappeared after the end of the 4th century. The change was brought about by two causes—first, Greek theology, which reached the West chiefly through Jerome Rufinus and Ambrose, and, second, the new idea of the church wrought out by Augustine on the basis of the altered political situation of the church. Augustine was the first who ventured to teach that the catholic church, in its empirical form, was the kingdom of Christ, that the millennial kingdom had commenced with the appearing of Christ, and was therefore an accomplished fact. By this doctrine of Augustine's, the old millennarianism, though not completely extirpated, was at least banished from the official theology. It still lived on, however, in the lower strata of Christian society; and in certain undercurrents of tradition it was transmitted from century to century. At various periods in the history of the middle ages we encounter sudden outbreaks of millennarianism, sometimes as the tenet of a small sect, sometimes as a far-reaching movement. And, since it had been suppressed, not, as in the East, by mystical speculation, its mightiest antagonist, but by the political church of the hierarchy, we find that wherever chiliasm appears in the middle ages it makes common cause with all enemies of the secularized church. It strengthened the hands of church democracy; it formed an alliance with the pure souls who held up to the church the ideal of apostolic poverty; it united itself for a time even with mysticism in a common opposition to the supremacy of the church; nay, it lent the strength of its convictions to the support of states and princes in their efforts to break the political power of the church. It is sufficient to recall the well-known names of Joachim of Floris, of all the numerous Franciscan spiritualists, of the leading sectaries from the 13th to the 15th century who assailed the papacy and the secularism of the church—above all, the name of Occam. In these men the millennarianism of the ancient church came to life again; and in the revolutionary movements of the 15th and 16th centuries—especially in the Anabaptist movements—it appears with all its old uncompromising energy. If the church, and not the state, was regarded as Babylon, and the pope declared to be the Antichrist, these were legitimate inferences from the ancient traditions and the actual position of the church. But, of course, the new chiliasm was not in every respect identical with the old. It could not hold its ground without admitting certain innovations. The "everlasting gospel" of Joachim of Floris was a different thing from the announcement of Christ's glorious return in the clouds of heaven; the "age of the spirit" which mystics and spiritualists expected contained traits which must be characterized as "modern"; and the "kingdom" of the Anabaptists in Münster was a Satanic caricature of that kingdom in which the Christians of the 2nd century looked for a peaceful Sabbath rest. Only we must not form our ideas of the great apocalyptic and chiliastic movement of the first decades of the 16th century from the rabble in Münster. There were pure evangelical forces at work in it; and many Anabaptists need not shun comparison with the Christians of the apostolic and post-apostolic ages.

The German and Swiss Reformers also believed that the end of the world was near, but they had different aims in view from those of the Anabaptists. It was not from poverty and apocalypticism that they hoped for a reformation of the Church. In contrast to the fanatics, after a brief hesitation they threw millennarianism overboard, and along with it all other "opiniones Judaicae." They took up the same ground in this respect which the Roman Catholic Church had occupied since the time of Augustine. How millennarianism nevertheless found its way, with the help of apocalyptic mysticism and Anabaptist influences into the churches of the Reformation, chiefly among the Reformed sects, but afterwards also in the Lutheran Church, how it became incorporated with Pietism, how in more recent times an exceedingly mild type of "academic" chiliasm has been developed from a belief in the verbal inspiration of the Bible, how finally new sects are still springing up here and there with apocalyptic and chiliastic expectations—these are matters which cannot be fully entered upon here.

MILLER, HUGH (1802–1856), Scottish geologist and man of letters, was born in humble circumstances at Cromarty, on the 10th of October 1802; his father, Hugh Miller, a seaman, was drowned when he was but five years old. His primary education was acquired at a dame's school and afterwards at the parish school, and at the age of six he had learned that "the art of reading is the art of finding stories in books." At the age of twelve he began to write verses. Two of his mother's brothers, James and "Sandy" Wright, hard-working men at Cromarty, offered to assist him to enter the ministry, but he felt no call to the sacred office, and from 1820 to 1822 he was apprenticed to a stone-mason. During the next few years he obtained employment as a journeyman mason in Edinburgh, Inverness and various other parts of Scotland. The writing of verses occupied his leisure hours, and in 1826 he sent to the *Scotsman* an "Ode on Greece" which was refused. It was not until 1829 that he met with his first success in the publication of *Poems written in the Leisure Hours of a Journeyman Mason.* These were printed and issued from the office of the *Inverness Courier*. Miller now turned his attention to prose and contributed many essays to the *Inverness Courier*. As remarked by Sir A. Geikie, "These made so favourable an impression that they were soon afterwards reprinted separately. They marked the advent of a writer gifted with no ordinary powers of narration and with the command of a pure, nervous and masculine style."

At the age of thirty-two he was still a stone-mason, but in the latter part of 1834 he was offered a post as accountant in the Commercial Bank of Scotland, and was almost immediately transferred to the Cromarty branch. His prose writings had now attracted much notice, and he next issued in 1835 *Scenes and Legends of the North of Scotland, or the traditional history of Cromarty*, in which he introduced some memoranda on the geology. This work met with a cordial reception. Miller, while still a stone-mason, had observed the abundant fossils in the Jurassic shales on the shores of Ethie, but it was not until 1830 that he first obtained remains of fossil fishes in the Old Red Sandstone. These for many years he collected and studied as far as he could, and in 1837 some of his specimens were brought to the notice of R. I. Murchison and Professor Agassiz. In the following year he was in communication with Murchison and his career as a geologist was definitely opened.

In 1837 Miller married Lydia Falconer Frazer (1811?–1876), a lady of good position and great natural ability, whom he had met six years previously. He set up his household in Cromarty, on a salary of sixty pounds a year, aided by the small sums he then earned by literary work; and his wife took a few pupils. Mrs Miller eventually became well known under the pseudonym of Mrs Harriet Myrtle as author of the *Ocean Child* (1857) and other story-books for children.

Soon after his marriage, Miller became greatly stirred by the internal dissensions in the Church of Scotland, of which he was a staunch member, and he published two pamphlets which brought him to the notice of some of the prominent members of the liberal church party. In 1839 he went by invitation to Edinburgh to edit a new Whig newspaper, the *Witness*, which was intended to support the views of those who after the disruption in 1843 formed the Free Church. The paper rapidly attained a large circulation; and this was no doubt largely due to his own literary and scientific essays. In 1840 he contributed a series of articles on *The Old Red Sandstone*, and these were reprinted in book form in the following year. The charm of this work was widely appreciated, as was also the natural sagacity shown in the descriptions and restorations of some of the fossil fishes. His *Footprints of the Creator* was published in 1849, and *My Schools and Schoolmasters* in 1854. He was engaged on the final proofs of his *Testimony of the Rocks* on the day of his death. During the last year of his life he suffered from inflammation of the lungs; and the strain of ill-health proving too severe, he died by his own hand in Edinburgh on the 23rd of December 1856. By request of his wife, *The Cruise of the Betsey, with Rambles of a Geologist* (1858) previously printed only in the *Witness* newspaper was published under the editorship of the Rev. W. S. Symonds.

In memory of Hugh Miller a monument was erected by public subscription in 1860 at Cromarty; and the cottage in which he was born was acquired at a later period by his son Hugh. In it have been placed part of his library, a set of the *Witness* newspaper, some letters addressed to him, and a number of geological specimens, including many referred to in his *Old Red Sandstone.* On the 22nd of August 1902 the centenary of his birth was celebrated at Cromarty, and was attended by scientific representatives from all parts of the world.

His elder son, Hugh Miller (1850–1896), passed through the Royal School of Mines and joined the Geological Survey in England in 1873; afterwards he was transferred to Scotland and surveyed the country around Cromarty and other parts of Ross-shire and Sutherlandshire. He was author of *Landscape Geology*, 1891.

See *The Life and Letters of Hugh Miller*, by Peter Bayne (2 vols., 1871); *Hugh Miller; his work and influence*, address by Sir A. Geikie, at the centenary celebration. (H. B. Wo.)

MILLER, JOAQUIN (CINCINNATUS HEINE) (1841–), American poet, was born in Indiana, on the 10th of November 1841, and was educated for the law. After some experiences of mining and journalism in Idaho and Oregon, he settled down in 1866 as judge in Grant county, Oregon, and during his four years' tenure of this post he began to write verse. In 1870 he travelled in Europe, and in 1871 he published his first volume of poetry, full of tropical passion, *Songs of the Sierras*, on which his reputation mainly rests. His *Songs of the Sunlands* (1873) followed in the same vein, and after other volumes had appeared, his *Collected Poems* were published in 1882. He also wrote plays, *The Danites in the Sierras* having some success as a sensational melodrama. On his return from Europe he became a journalist in Washington, but in 1887 returned to California. His pen-name, "Joaquin Miller," by which he is known, was assumed by him when he published his first book, in consequence of his having written an article in defence of Joaquin Murietta, the Mexican brigand.

Revised editions of his *Complete Poetical Works* appeared at San Francisco in 1902.

MILLER, JOE (JOSEPH or JOSIAS((1684–1738), English actor, first appears in the cast of Sir Robert Howard's *Committee* at Drury Lane in 1709 as Teague. Trinculo in *The Tempest*, the First Grave-digger in *Hamlet* and Marplot in *The Busybody*, were among his many favourite parts. He is said to have been a friend of Hogarth. He died on the 16th of August 1738. After his death, John Mottley (1692–1750) brought out a book called *Joe Miller's Jests, or Wit's Vade Mecum* (1739), a collection of contemporary and ancient coarse witticisms, only three of which are told of Miller. Owing to the quality of the jokes in Mottley's book, their number increasing with each of the many subsequent editions, any time-worn jest has, somewhat unjustly, come to be called "a Joe Miller."

MILLER, SAMUEL FREEMAN (1816–1890), American jurist, was born in Richmond, Kentucky, on the 5th of April 1816, of Pennsylvania-German stock. He was brought up on a farm, was a clerk in a drug-store, graduated from the medical department of Transylvania University in 1838, and practised medicine in Barboursville, Kentucky, until 1847. In that year he was admitted to the bar, and entered politics as a Whig. His anti-slavery sympathies induced him to settle in Iowa, where in 1850 he freed his slaves and began to practise law in Keokuk, and he soon became a leader of the Republican party in the state. In 1862 he succeeded Justice Peter V. Daniel (1784–1860), as a justice of the U.S. Supreme Court, and served until his death in Washington, D.C., on the 13th of October 1890, when he was senior justice. Miller was a man of great mental force and individuality, and his judgments carried great weight. In 1877 he was a member of the electoral commission, which adopted his motion that Congress could not "go behind the returns" as properly accredited by state officials. He was a prominent member of the Unitarian Church and for three years was president of its national conference. He published a volume of *Lectures on the Constitution of the United States* (New York, 1891).

See Wm. A. Maury, in *The Juridical Review of Edinburgh* (for January 1891), and Chas. M. Gregory, in *Yale Law Journal* (for April 1908).

MILLER, WILLIAM (1782–1849), leader of the Second Adventists in America, was born on the 5th of February 1782 at Pittsfield, Massachusetts. He was a recruiting officer at the beginning of the War of 1812, and after Plattsburg he was promoted captain, retiring from the army in 1815. About 1816 he settled in Low Hampton, Washington county, New York.

He now joined the Baptist Church at Low Hampton, and, after two years of minute study of the Bible, about 1818 became a Second Adventist. In 1831 he began to lecture, arguing that the "two thousand three hundred days" of Daniel viii. 14 meant 2300 years, and that these years began with Ezra's going up to Jerusalem in 457 B.C., and therefore came to an end in 1843, and urging his hearers to make ready for the final coming of Christ in that year. To his many followers, after the year 1843 had passed, he proclaimed that 1844 was the year, that his error was due to following Hebrew instead of Roman chronology, and that the 22nd of October was to be the day. There was renewed excitement among Miller's followers; many of them left their business, and in white muslin robes, on house tops and hills, awaited the epiphany. In spite of disappointment, many still believed with him that the time was near. He returned to Low Hampton and died there on the 20th of December 1849. The Adventists or Millerites, who were formed into a single body in a convention called by him in April 1845, have since separated into several sects: the Evangelical Adventists (1147 in the United States in 1908), who believe in everlasting punishment; the Seventh Day Adventists (64,332), who observe the seventh day, and practise the sacrament of foot-washing; the Advent Christians (26,500), the Churches of God in Jesus Christ (2872), and the Life and Advent Union (3800). Their total number in the United States in 1908 was about 99,300. Miller published in 1833 a pamphlet which was the basis of his lectures; these were published in 1842 as *Evidence from Scripture and History of the Second Coming of Christ about the Year 1843.*

See Sylvester Bliss, *Memoirs of William Miller* (Boston, 1853); James White, *Sketches of the Christian Life and Public Labors of William Miller* (Battle Creek, 1875); and Edward Eggleston's novel, *End of the World* (1872).

MILLER, WILLIAM (1795–1861), British soldier, who took a prominent part in the South American Wars of Liberation, entered the British artillery service in 1811, and till 1814 he was continuously on active service with Wellington's army in the Peninsula. In the latter year he accompanied the ill-fated New Orleans expedition. After the general peace he travelled for two years about Europe, and then went to South America. The war which culminated in the expulsion of the Spaniards was just breaking out, and he took command in the Chilean artillery, with which he served during the Chilean part of the war. As a major he commanded the marines on Cochrane's vessel, the "O'Higgins." In 1821 he landed in Peru, to assist General San Martin against the Spanish General Canterac. He was made general of brigade, and became very intimate with Simon Bolivar. He rendered the most conspicuous services at Junin (Aug. 6, 1824), and his regiment, the "Hussars of Junin," covered itself with glory in the decisive victory of Ayacucho (Dec. 9, 1824). From 1830 to 1839 he filled various high military and political offices in Peru. In the latter year he was involved in the fall of Santa Cruz, and went into exile. For some years he filled the post of British Consul-General of the Pacific Coast. He died on board H.M.S. "Naiad" at Callao, on the 31st of October 1861.

See the *Memoirs* published by his brother John Miller (London, 1827).

MILLER, WILLIAM (1796–1882), Scottish line-engraver, was born in Edinburgh on the 28th of May 1796. After studying in London under George Cook, a pupil of Basire's, he returned to Edinburgh. He executed plates after Thomson of Duddingston, Macculloch, D. O. Hill, Sir George Harvey, and other Scottish landscapists, but his chief works were his transcripts from Turner. The first of these was the Clovelly (1824), of *The Southern Coast*, a publication undertaken by George Cook and his brother William B. Cook, to which Miller also contributed the Combe Martin and the Portsmouth. He was engaged on the illustrations of *England and Wales*, 1827–1838; of *The Rivers of France*, 1833–1835; of Roger's *Poems*, 1834; and very largely on those of *The Prose and Poetical Works of Sir Walter Scott*, 1834. In *The Provincial Antiquities and Picturesque Scenery of Scotland*, 1826, he executed a few excellent plates after Thomson and Turner. Among his larger engravings of Turner's works may be mentioned "The Grand Canal, Venice"; "The Rhine. Osterprey and Feltzen"; "The Bell Rock"; "The Tower of London"; and "The Shepherd." The art of William Miller was warmly appreciated by Turner himself, and Ruskin pronounced him to be on the whole the most successful translator into line of the paintings of the greatest English landscapist. His renderings of complex Turnerian sky-effects are especially delicate and masterly. Towards the end of his life Miller abandoned engraving and occupied his leisure in the production of water-colours, many of which were exhibited in the Royal Scottish Academy, of which he was an honorary member. He resumed his burin, however, to produce two final series of vignettes from drawings by Birket Foster illustrative of Hood's *Poems*, published by Moxon in 1871. Miller, who was a Quaker, died on the 20th of January 1882.

MILLER, WILLIAM HALLOWES (1801–1880), British mineralogist and crystallographer, was born at Velindre near Llandovery, Carmarthenshire, on the 6th of April 1801. He was educated at St John's College, Cambridge, where he graduated in 1826 as fifth wrangler, and became a fellow in 1829. For a few years he was occupied as a college tutor and during this time he published treatises on hydrostatics and hydrodynamics. He also gave special attention to crystallography, and on the resignation of W. Whewell he succeeded in 1832 to the professorship of mineralogy, a post which he occupied until 1870. His chief work, on *Crystallography*, was published in 1838. He was elected F.R.S. in 1838. In 1852 he edited a new edition of H. J. Brooke's *Elementary Introduction to Mineralogy*. He assisted in 1843 the committee appointed to superintend the construction of the new Parliamentary standards of length and weight (see *Phil. Trans.*, 1856). He died in Cambridge on the 20th of May 1880.

MILLERAND, ALEXANDRE (1859–), French socialist and politician, was born in Paris on the 10th of February 1859. He was educated for the bar, and made his reputation by his defence, in company with Georges Laguerre, of Ernest Roche and Duc-Quercy, the instigators of the strike at Decazeville in 1883; he then took Laguerre's place on M. Clemenceau's paper, *La Justice*. He was elected to the Chamber of Deputies for the department of the Seine in 1885 as a radical socialist. He was associated with MM. Clemenceau and Camille Pelletan as an arbitrator in the Carmaux strike (1892). He had long had the ear of the Chamber in matters of social legislation, and after the Panama scandals had discredited so many politicians his influence grew. He was chief of the Socialist left, which then mustered sixty members, and edited until 1896 their organ in the press, *La Petite République*. His programme included the collective ownership of the means of production and the international association of labour, but when in June 1899 he entered Waldeck-Rousseau's cabinet of "republican defence" as minister of commerce he limited himself to practical reforms, devoting his attention to the improvement of the mercantile marine, to the development of trade, of technical education, of the postal system, and to the amelioration of the conditions of labour. Labour questions were entrusted to a separate department, the Direction du Travail, and the pension and insurance office was also raised to the status of a "direction." The introduction of trades-union representatives on the Supreme Labour Council, the organization of local labour councils, and the instructions to factory inspectors to put themselves in communication with the councils of the trades-unions, were valuable concessions to labour, and he further secured the rigorous application of earlier laws devised for the protection of the working-classes. His name was especially associated with a project for the establishment of old age pensions, which became law in 1905. He became in 1898 editor of *La Lanterne*. His influence with the extreme Socialists had already declined, for it was said that his departure from the true Marxist tradition had disintegrated the party.

For his administration in the Waldeck-Rousseau cabinet see A. Lavy, *L'Œuvre de Millerand* (1902); his speeches between 1899 and 1907 were published in 1907 as *Travail et travailleurs*.

MILLERITE, a mineral consisting of nickel sulphide, NiS. Crystals belong to the rhombohedral system and have the form of slender needles arranged in divergent groups or of delicate fibres loosely matted together. The colour is brass-yellow and the lustre metallic. Before the chemical composition of the mineral had been determined it had been known as "capillary pyrites" or "hair pyrites" (Ger., *Haarkies*), and was not distinguished from the capillary forms of pyrites and marcasite: the name millerite was given by W. Haidinger in 1845, in honour of W. H. Miller. The hardness is 3–3½ and the specific gravity 5·65. There are perfect cleavages parallel to the faces of the rhombohedron (100); and gliding planes parallel to the faces of the rhombohedron (110), on which secondary twinning may be readily produced artificially by pressure.

Typical specimens of millerite are found in the coal measures in the neighbourhood of Merthyr Tydvil in South Wales, where the delicate needles and fibres occur with crystals of quartz and pearl-spar in the fissures of septarian nodules of clay-ironstone. Radiating groups of needles are found with ankerite in cavities in haematite in the Sterling mine at Antwerp in Jefferson county, New York. At the Gap mine in Lancaster county, Pennsylvania, the mineral occurs as fibrous encrusting masses with a velvety lustre. The most perfect crystals are those formerly found with calcite, diopside and a bright green chrome-garnet in a nickel mine at Orford in Sherbrooke county, Quebec. (L. J. S.)

MILLER'S THUMB (*Cottus gobio*), a small fish, abundant in all rivers and lakes of northern and central Europe with clear water and gravelly bottom. The genus *Cottus*, to which the miller's thumb belongs, is easily recognized by its broad, flat head, rounded and scaleless body, large pectoral and narrow ventral fins, with two dorsal fins, the anterior shorter than the posterior; the praeoperculum is armed with a simple or branched spine. The species of the genus *Cottus* are rather numerous, and are confined to the north temperate zone of the globe, the majority being marine, and known by the name of "bullheads." The miller's thumb is confined to fresh water; and only one other freshwater species is found in Europe, *C. poecilopus*, from rivers of Hungary, Galicia, and the Pyrenees; some others occur in the fresh waters of northern Asia and North America. The miller's thumb is common in all suitable localities in Great Britain, but is extremely rare in Ireland; in the Alps it reaches to an altitude exceeding 7000 ft. Its usual length is from 3 to 5 in. Generally hidden under a stone or in a hollow of the bank, it watches for its prey, which consists of small aquatic animals, and darts when disturbed with extraordinary rapidity to some other place of refuge. The female deposits her ova in a cavity under a stone, whilst the male watches and defends them until the young are hatched and able to shift for themselves.

MILLET, FRANCIS DAVIS (1846–), American artist, was born at Mattapoisett, Massachusetts, on the 3rd of November 1846. He was a drummer boy with the Union forces in the Civil War; graduated from Harvard College in 1869; and in 1871 entered the Royal Academy of Fine Arts, Antwerp, where he studied under Van Lerius and De Keyser. In 1873 he was made secretary of the Massachusetts commission to the Vienna Exposition. During the Russo-Turkish War of 1877–78 he was correspondent of the London *Daily News* and *Graphic*, and of the *New York Herald*. On his return he was made a member from the United States of the International Art Jury at the Paris Exposition of 1878. He was director of decorations at the Columbian Exposition, Chicago, 1893, and in 1898 he went to Manila as war correspondent for *The Times* and for *Harper's Weekly*. In 1880 he became a member of the Society of American Artists, and in 1885 was elected to full membership in the National Academy of Design, New York, and was for one term its vice-president; he became a member also of the American Water Color Society and of the Institute of Painters in Oil Colours, London. As a decorative artist his work may be seen at Trinity Church, Boston; the Bank of Pittsburg; and the Capitol at St Paul, Minnesota. His pictures are in many public collections: among them are "A Cosy Corner," in the Metropolitan Museum of Art, New York; "At the Inn," in the Union League Club, New York; and "Between two Fires," in the Tate Gallery, London. He also wrote essays and short stories, and an English version of Tolstoi's *Sebastopol* (1887); and among his publications are *The Danube* (1891), *Capillary Crime and other Stories* (1892), and *Expedition to the Philippines* (1899).

MILLET (or **MILÉ**), **JEAN FRANÇOIS** (*c.* 1642–1679), commonly called FRANCISQUE, was born at Antwerp about 1642, and is generally classed amongst the painters of Flanders on account of the accident of his birth. But his father was a Frenchman, a turner in ivory of Dijon, who took service with the prince of Condé and probably returned after a time to his native country. He remained long enough in Antwerp to apprentice his son to an obscure member of a painter family called Laurent, pupil of Gabriel Franck. With Laurent, Francisque left Antwerp for Paris, and there settled in 1660 after marrying his master's daughter. He was received a member of the Academy of Painting at Paris in 1673, and after gaining consideration as an imitator of the Poussins he died in 1679, bequeathing his art and some of his talents to one of his sons. Francisque probably knew, as well as imitated, Nicolas Poussin, Gaspar Dughet and Sebastian Bourdon; and it is doubtless because of his acquaintance with these travelled artists that, being himself without familiarity with the classic lands of Italy and Greece, he was able to imagine and reproduce Italian and Arcadian scenery with considerable grace and effectiveness. It is indeed surprising to observe, even at this day how skilfully he executed these imaginary subjects, enlivened them with appropriate figures, and shed over them the glow of a warm yet fresh and sparkling tone. Twelve of his most important landscapes, which remained in the palace of the Tuileries, were destroyed by fire; and though many of his pieces may still be found catalogued in Continental and English collections, others in great number remain unknown and unacknowledged.

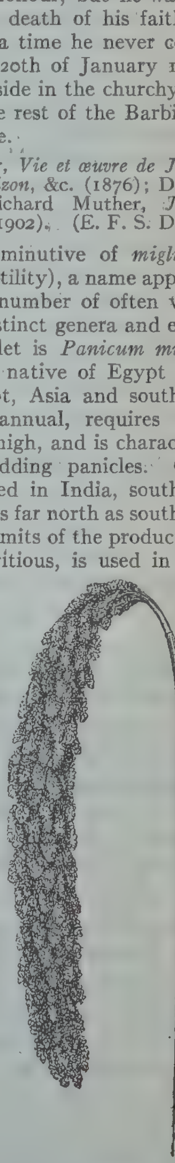
His son JEAN FRANÇOIS MILLET, the younger (1666–1723), also called Francisque, was born in Paris, and was made a member of the Academy of Painting in 1709. He is not quite so independent in his art as his father; but he had clever friends, and when he wanted figures to his landscapes, he consulted Watteau, and other followers of the "court shepherdess" school. In the museum of Grenoble is a "Paysage" by him which is prettily adorned with Watteau's figures.

MILLET, JEAN FRANÇOIS (1814–1875), French painter, who came of a peasant family, was born on the 4th of October 1814 in the hamlet of Gruchy, near Gréville (La Manche), in the wild and picturesque district called La Hague. His boyhood was passed working in his father's fields, but the sight of the engravings in an old illustrated Bible set him drawing, and thenceforth, whilst the others slept, the daily hour of rest was spent by Millet in trying to render the familiar scenes around him. From the village priest the lad learnt to read the Bible and Virgil in Latin, and acquired an interest in one or two other works of a high class which accompanied him through life; he did not, however, attract attention so much by his acquirements as by the stamp of his mind. The whole family seems, indeed, to have worn a character of austerity and dignity, and when Millet's father finally decided to test the vocation of his son as an artist, it was with a gravity and authority which recalls the patriarchal households of Calvinist France. Two drawings were prepared and placed before a painter at Cherbourg named Mouchel, who at once recognized the boy's gifts, and accepted him as a pupil; but shortly after (1835) Millet's father died, and the eldest son, with heroic devotion, took his place at home, nor did he return to his work until the pressing calls from without were solemnly enforced by the wishes of his own family. He accordingly went back to Cherbourg, but after a short time spent there with another master (Langlois) started with many misgivings for Paris. The council-general of the department had granted him a sum of 600 francs, and the town council promised an annual pension of 400, but in spite of friendly help and introductions Millet went through great difficulties. The system of the École des Beaux Arts was hateful to him, and it was not until after much hesitation that he decided to enter an official studio—that of Delaroche. The master was certainly puzzled by his pupil; he saw his ability, and, when Millet in his poverty could not longer pay the monthly fees, arranged for his free admission to the studio, but he tried in vain to make him take the approved direction, and lessons ended with "Eh, bien, allez à votre guise, vous êtes si nouveau pour moi que je ne veux rien vous dire." At last, when the competition for the Grand Prix came on, Delaroche gave Millet to understand that he intended to secure the nomination of another, and thereupon Millet withdrew himself, and with his friend Marolle started in a little studio in the Rue de l'Est. He had renounced the beaten track, but he continued to study hard whilst he sought to procure bread by painting portraits at 10 or 15 francs apiece and producing small "pastiches" of Watteau and Boucher. In 1840 Millet went back to Gréville, where he painted "Sailors Mending a Sail" and a few other pictures—reminiscences of Cherbourg life.

His first success was obtained in 1844, when his "Milkwoman" and "Lesson in Riding" (pastel) attracted notice at the Salon, and friendly artists presented themselves at his lodgings only to learn that his wife had just died, and that he himself had disappeared. Millet was at Cherbourg; there he remarried, but having amassed a few hundred francs he went back to Paris and presented his "St Jerome" at the Salon of 1845. This picture was rejected and exists no longer, for Millet, short of canvas, painted over it "Oedipus Unbound," a work which during the following year was the object of violent criticism. He was, however, no longer alone; Diaz, Eugène Tourneux, Rousseau, and other men of note supported him by their confidence and friendship, and he had by his side the brave Catherine Lemaire, his second wife, a woman who bore poverty with dignity and gave courage to her husband through the cruel trials in which he penetrated by a terrible personal experience the bitter secrets of the very poor. To this date belong Millet's "Golden Age," "Bird Nesters," "Young Girl and Lamb," and "Bathers"; but to the "Bathers" (Louvre) succeeded "The Mother Asking Alms," "The Workman's Monday," and "The Winnower." This last work, exhibited in 1848, obtained conspicuous success, but did not sell till Ledru Rollin, informed of the painter's dire distress, gave him 500 francs for it, and accompanied the purchase with a commission, the money for which enabled Millet to leave Paris for Barbizon, a village on the skirts of the forest of Fontainebleau. There he settled in a three-roomed cottage for the rest of his life—twenty-seven years, in which he wrought out the perfect story of that peasant life of which he alone has given a "complete impression." Jules Breton has coloured the days of toil with sentiment; others, like Courbet, whose eccentric "Funeral at Ornans" attracted more notice at the Salon of 1850 than Millet's "Sowers and Binders," have treated similar subjects as a vehicle for protest against social misery; Millet alone, a peasant and a miserable one himself, saw true, neither softening nor exaggerating what he saw. In a curious letter written to M. Sensier at this date (1850) Millet expressed his resolve to break once and for all with mythological and undraped subjects, and the names of the principal works painted subsequently will show how steadfastly this resolution was kept. In 1852 he produced "Girls Sewing," "Man Spreading Manure"; 1853, "The Reapers"; 1854, "Church at Gréville"; 1855—the year of the International Exhibition, at which he received a medal of second class—"Peasant Grafting a Tree"; 1857, "The Gleaners"; 1859, "The Angelus," "The Woodcutter and Death"; 1860, "Sheep Shearing"; 1861, "Woman Shearing Sheep," "Woman Feeding Child"; 1862, "Potato Planters," "Winter and the Crows"; 1863, "Man with Hoe," "Woman Carding"; 1864, "Shepherds and Flock, Peasants Bringing Home a Calf Born in the Fields"; 1869, "Knitting Lesson"; 1870, "Buttermaking; 1871, "November—recollection of Gruchy." Any one of these works will show how great an influence Millet's previous practice in the nude had upon his style. The dresses worn by his figures are not clothes, but drapery through which the forms and movements of the body are strongly felt, and their contour shows a grand breadth of line which strikes the eye at once. Something of the imposing unity of his work was also, no doubt, due to an extraordinary power of memory, which enabled Millet to paint (like Horace Vernet) without a model; he could recall with precision the smallest details of attitudes or gestures which he proposed to represent. Thus he could count on presenting free from afterthoughts the vivid impressions which he had first received, and Millet's nature was such that the impressions which he received were always of a serious and often of a noble order, to which the character of his execution responded so perfectly that even a "Washerwoman at her Tub" will show the grand action of a Medea. The drawing of this subject is reproduced in *Souvenirs de Barbizon*, a pamphlet in which M. Piédagnel has recorded a visit paid to Millet in 1864. His circumstances were then less evil, after struggles as severe as those endured in Paris. A contract by which he bound himself in 1860 to give up all his work for three years had placed him in possession of 1000 francs a month. His fame extended, and at the exhibition of 1867 he received a medal of the first class, and the ribbon of the Legion of Honour, but he was at the same moment deeply shaken by the death of his faithful friend Rousseau. Though he rallied for a time he never completely recovered his health, and on the 20th of January 1875 he died. He was buried by his friend's side in the churchyard of Chailly. His pictures, like those of the rest of the Barbizon school, have since greatly increased in value.

See the article BARBIZON; also A. Sensier, *Vie et œuvre de J. F. Millet* (1874); Piédagnel, *Souvenirs de Barbizon*, &c. (1876); D. C. Thomson, *The Barbizon School* (1891); Richard Muther, *J. F. Millet* (1905); Gensel, *Millet und Rousseau* (1902). (E. F. S. D.)

MILLET (Fr. *millet*; Ital. *miglietto*, diminutive of *miglio* = Lat. mille, a thousand, in allusion to its fertility), a name applied with little definiteness to a considerable number of often very variable species of cereals, belonging to distinct genera and even subfamilies of Gramineae. Common millet is *Panicum miliaceum* (German *Hirse*). It is probably a native of Egypt and Arabia but has been cultivated in Egypt, Asia and southern Europe from prehistoric times. It is annual, requires rich but friable soil, grows to about 3 or 4 ft. high, and is characterized by its bristly, much branched nodding panicles. One variety has black grains. It is cultivated in India, southern Europe, and northern Africa, and ripens as far north as southern Germany, in fact, wherever the climate admits of the production of wine. The grain, which is very nutritious, is used in the form of groats, and makes excellent bread when mixed with wheaten flour. It is also largely used for feeding poultry, for which purpose mainly it is imported. Hungarian grass, *Setaria italica* (also called *Panicum italicum*), a native of eastern Asia is one of the most wholesome and palatable Indian cereals. It is annual, grows 4 to 5 ft. high, and requires dry light soil. German Millet (Ger. *Kolbenhirse*, *Mohar*) is probably merely a less valuable and dwarf variety of *S. italica*, having an erect, compact, and shorter spike. The grains of both are very small, only one half as long as those of common millet, but are exceedingly prolific. Many stalks arise from a single root, and a single spike often yields 2 oz. of grain, the total yield being five times that of wheat. They are imported for poultry feeding like the former species and for cage-birds, but are extensively used in soups, &c., on the Continent. Numerous other species belonging to the vast genus *Panicum*—the largest among grasses, of which the following are among the most important—are also cultivated in tropical or subtropical countries for their grain or as fodder



Setaria italica.

grasses, or both, each variety of soil, from swamp to desert, having its characteristic forms.

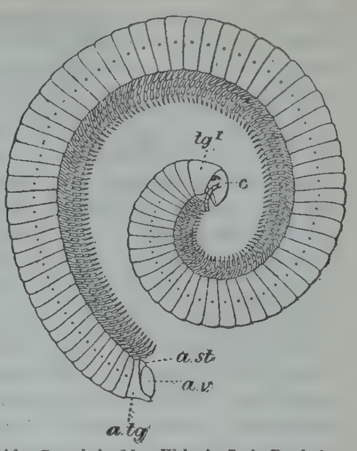
Polish millet is *P. sanguinale*; *P. frumentaceum*, shamalo, a Deccan grass, is probably a native of tropical Africa; *P. decompositum* is the Australian millet, its grains being made into cakes by the aborigines. *P. maximum* is the Guinea grass, native of tropical Africa; it is perennial, grows 8 ft. high, and yields abundance of highly nutritious grain. *P. spectabile* is the coapim of Angola, but has been acclimatized in Brazil and other tropical countries. Other gigantic species 6 or 7 ft. high form the field-crops on the banks of the Amazon. Of species belonging to allied genera, *Pennisetum typhoideum*, bajree, sometimes also called Egyptian millet or pearl millet, is largely cultivated in tropical Asia, Nubia and Egypt. Species of *Paspalum*, *Eleusine* and *Milium*, are also cultivated as millets. For Indian millet, see DURRA.

MILLIGAN, WILLIAM (1821–1892), Scottish theologian, was born on the 15th of March 1821, the eldest son of the Rev. George Milligan and his wife Janet Fraser. He was educated at the High School, Edinburgh, and, from the age of fourteen, at the university of St Andrews, where he graduated in 1839. In 1843 at the disruption he took the side of those who remained in the Establishment, and in 1844 became minister of Cameron in Fifeshire. In 1845, his health having given way, he went to Germany, and studied at the university of Halle. After his return to Scotland and his resumption of his clerical duties he began to write articles on Biblical and critical subjects for various reviews. This led to his appointment in 1860 to the professorship of Biblical criticism in the university of Aberdeen. In 1870 he was appointed one of the committee for the revision of the translation of the New Testament. His fervent piety, and his wide interest in educational and social questions, extended his influence far beyond the circle of theologians. His contributions to periodical literature for many years were numerous and valuable; but his reputation chiefly rests on his works on the *Resurrection* (1890) and *Ascension of our Lord* (1892), his Baird lectures (1886) on the *Revelation of St John*, and his *Discussions* (1893) on that book. All these volumes are distinguished by great learning and acuteness, as well as by breadth and originality of view. He died on the 11th of December 1892.

MILLINER, originally a dealer in goods from the city of Milan in Italy, whence the name. Such goods were chiefly steel work, including cutlery, needles, also arms and armour and textile fabrics, ribbons, gloves and "Milan bonnets." The "milliners" of London, though never formed into a Livery Company seem to have been associated with the "Cappers and Hurers," which later were amalgamated with the "Haberdashers" (*q.v.*). Minsheu's derivation of the word from *mille*, thousand ("as having a thousand small wares to sell"), though a typical instance of guessing etymologies, shows the miscellaneous character of their trade in the 16th and 17th centuries. The modern use of the word is confined chiefly to one who makes and sells bonnets and hats for women; but articles of "millinery" include ribbons, laces, &c., usually retailed by haberdashers.

MILLIPEDE, the popular name of the best known members of a group of the Arthropoda, scientifically known as Diplopoda, and formerly united with the Chilopoda (see CENTIPEDE), the Pauropoda and the Symphyla as an order of the class Myriapoda. This classification, however, has of late years been abandoned on account of the recognition of closer affinity between the Chilopoda (centipedes) and the Hexapoda (insects) than between the Chilopoda and Diplopoda. By modern writers the above-mentioned groups of "tracheate" Arthropoda are either regarded as independent classes of this phylum Arthropoda, or associated in two superclasses, the Opisthogonea or Opisthogoneata for the Chilopoda and Hexapoda; and the Prosogonea or Prosogoneata for the Diplopoda, Pauropoda and Symphyla. The structural character upon which these superclasses are based is the position of the generative apertures which open anteriorly in the Prosogonea and posteriorly in the Opisthogonea. Although the Pauropoda and Symphyla are not, strictly speaking, Diplopoda, these three groups of prosogoneate arthropods are here for convenience considered together.

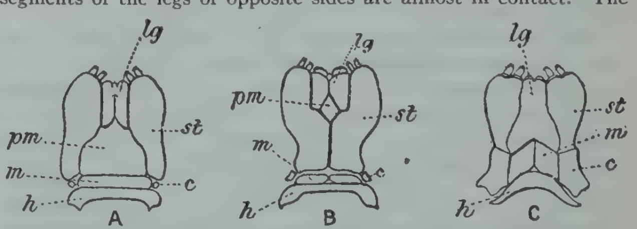
CLASS DIPLOPODA.



After Pocock in Max Weber's *Zool. Ergebnisse*, &c., IV., Pl. XXI., fig. 8, 1894.

FIG. 1.—*Spirostreptus vittatus*, an Oriental species of the Spirostreptoidea, lateral view, showing the repugnatorial pores on the sides of the segments.

c, head with eyes and antennae.
tg^1, tergal plate of first segment.
a.tg, tergal plate of last or anal segment.
a.st, sternal plate of ditto.
a.v, anal valve.



After Silvestri, *Ann. Mus. Genova*, (2), xvi, figs. 17, 19, 25.

FIG. 2.—The Gnathochilarium or jaws of second pair of various Chilongatha.

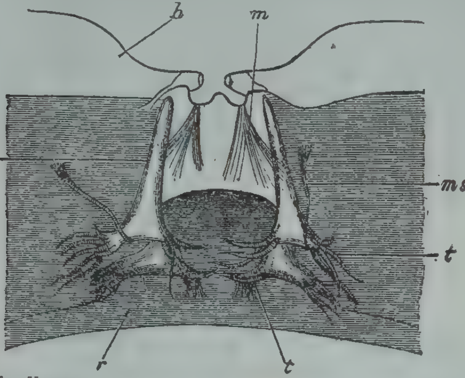
c, cardo.
st, stipes.
lg, linguae.
m, mentum.
pm, promentum.
h, hypostoma.

Structure.—The anterior extremity is provided with a distinct head which by its general form and the nature of its appendages is as sharply marked off from the body as is the case in the Hexapoda. It always bears at least three pairs of appendages, the eyes when present and, in the Oniscomorpha a peculiar sense organ. The inferior edge of the head plate overhangs the mouth and is termed the labrum. The exoskeleton of a typical somite consists of the following elements: a dorsal plate, a ventral plate, and a pleural plate on each side. To the external margin of the ventral plate or sternum is articulated a pair of legs and between the leg and the pleural plate is situated the spiracle of the tracheal system. But the segmentation of the Diplopoda presents two marked peculiarities. The first is the fact that, with the exception of a few of the anterior leg-bearing segments and perhaps one or two of those at the posterior end of the body, a single dorsal plate or tergum with its pleural plates overlies two sternal plates, two pairs of legs and two pairs of spiracles. Hence the segments appear to be double and to be furnished with twice as many legs as is normal in the Arthropoda—a peculiarity which has suggested the term "Diplopod" or "double-footed," for this group. It is generally believed that each tergal plate results from the coalescence of the terga of two originally distinct adjoining segments; but the same effect would be produced by the enlargement of one of a pair of terga and the complete excalation of the other. It is in favour of the latter view that there is only a single pair, and not two pairs, of stink-glands on each so-called double tergal plate. Unfortunately the history of the development of the segments does not clear up the difficulty since the terga of the double segments are single from the first, and no evidence either of fusion or excalation is supplied. The second of the two peculiarities above-mentioned is the great development of the tergal sclerite as compared with the sternal. Only very rarely (*i.e.* in *Platydesmus*) is there a broad sternal area. In the majority of cases the lateral edges of the tergum are bent downwards and inwards towards the mid ventral line; the sternum at the same time is so much reduced that the basal segments of the legs of opposite sides are almost in contact. The pleural plate on each side usually disappears either by suppression or by fusion with the tergum. The sterna with their attached legs often remain free. But quite commonly the coalescence of the skeletal elements is carried to such an extreme that each segment is a solid ring with two pairs of movable appendages. The last segment is differently constructed from the others. It is always limbless, and usually consists of a complete tergal ring, a single sternal plate, and a pair of movable anal valves which are normally closed, but are capable of being opened for the passage of faeces. These anal valves are possibly the homologues of the plural scutes of a normal segment. The appendages are modified as a single pair of antennae, two or three pairs of jaws and a variable number of walking-legs, of which one or more pairs may be transformed into gonopods. The antennae are short and very similar to the legs. They are preoral in position, and usually consist of seven segments, the seventh or distal segment being small, as a rule, and furnished with a sense organ which is probably olfactory or tactile in function. The mandibles or jaws of the first pair are the most anterior of the postoral appendages. They are large, powerful, and usually consist of three or two segments, a basal or cardo, which is sometimes absent, a second or stipes, and a third or mala, the latter being supplied with a strong tooth and pectinate lamellae. In all Diplopods, with the exception of the Pselaphognatha, there are only two pairs of jaws, those of the second pair forming a large plate, the gnathochilarium, which acts as a lower lip. It consists of several distinct sclerites, two external on each side, the proximal known as the cardo, the distal as the stipes, the latter being tipped with one or two lobes (malae) and far exceeding the cardo in size. Between the external plates there is a median proximal plate (mentum) generally of large size and often itself subdivided, and a pair of distal plates (linguae). Behind the base of the gnathochilarium there is a single large transverse plate, the hypostoma. In the Pselaphognatha, the jaws representing the gnathochilarium are differently constructed and an additional pair, the maxillulae, has been recently detected between the gnathochilarium and the mandibles. Behind the gnathochilarium, which from embryological data appears to result from the modification of a single pair of appendages, a legless somite has been detected in some embryos. Possibly the plate referred to above as the hypostoma is its sternal element.



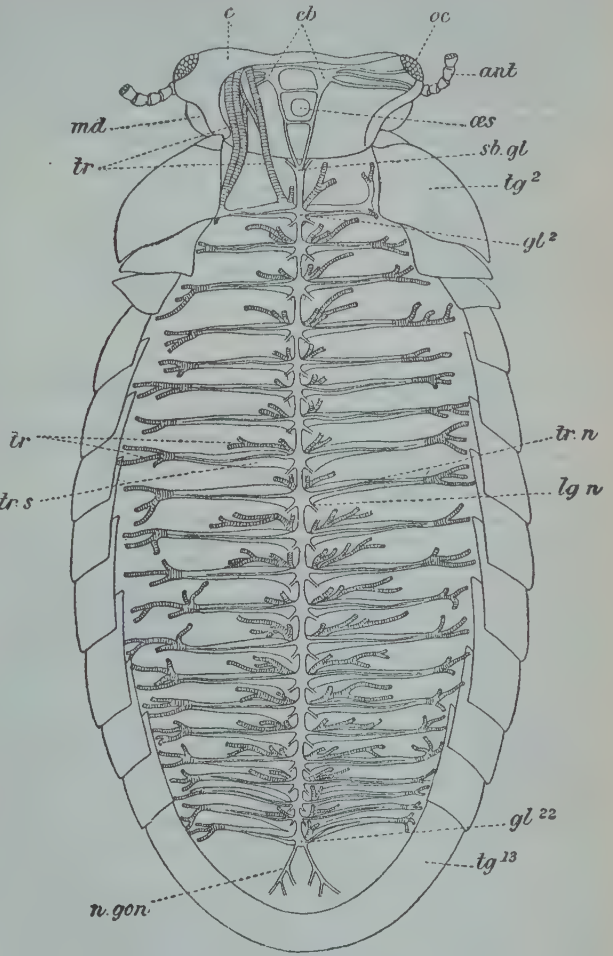
After Voges.

FIG. 3.—Inner view of ventral area of a single segment of *Julus*, much enlarged to show the structure and arrangement of the tracheal organs. The two pairs of tracheae are seen *in situ*, the posterior pair overlapping the anterior.

h, Posterior margin of the body-ring (tergum).
r, Anterior border.
st, Tubular chamber of tracheae.
t, Fine tracheae given off from it.
ms, Respiratory muscle attached to tracheal sac.
m, Ventral body muscle.

The heart is a median dorsal vessel composed of a series of chambers each giving off a pair of arteries and furnished with a pair of orifices or ostia. According to Newport, the anterior chamber lying in the second segment is prolonged into an aortic trunk from which arise three pairs of lateral arteries dipping down on each side of the alimentary canal and uniting beneath it in a common ventral vessel. The heart is enveloped in a delicate pericardial membrane and is supported by lateral alary muscles. The alimentary canal is a simple tube extending usually straight through the body from mouth to anus. Only in the Oniscomorpha is it looped, thus suggesting the origin of this short-bodied group of millipedes from longer, more vermiform ancestors. A pair of so-called salivary glands opens into the fore-gut near its anterior extremity and one or two pairs of malpighian tubes communicate with the hind-gut at its junction with the broad mesenteric portion of the canal. Respiration is effected by means of tracheal tubes which communicate with the exterior by means of spiracles situated just above the bases of the walking limbs. Each spiracle leads into a longer or a shorter pouch whence the tracheae, which are of two kinds, arise. In the majority of the orders the tracheae are tufted, that is to say, they form two bundles of short simple tubules springing from the innermost corners of each pouch. In the Oniscomorpha, however, each pouch gives rise to a number of long tubes which extend through the body and somewhat resemble those of the Chilopoda except that they neither branch nor are extensive. As in the Chilopoda and Hexapoda the tracheae are strengthened and kept expanded by a slender spiral filament.

The ventral nerve cord consists of two strands so closely approximated as to be practically fused, with a small ganglionic enlargement for each pair of legs. Hence in the double segments there are two such ganglia, which in addition to the crural nerve give off on each side a large branching nerve to other organs in the segment. In the Opisthospermophora (*Julus*, *Spirostreptus*) and the Oniscomorpha (*Glomeris*, *Sphaerotherium*) the ganglia are spaced at equal distances on the cord, but in the Merochaeta (*Polydesmus*) they are grouped in pairs to correspond to the spacing of the legs. The apodous penultimate and anal segments are innervated from the last ganglion of the cord, as are also the gonopods of the males of the Oniscomorpha. The first (suboesophageal) ganglion of the cord supplies the mandibles and gnathochilarium and is connected by the oesophageal commissures with the bilobed cerebral nerve whence arises the nerves for the eyes, when present, and the antennae.



After G. C. Bourne, *J. Linn. Soc.* xix., Pl. 29, 1886.

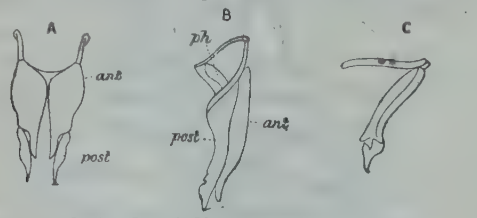
oc, Eye-cluster.
ant, Antenna.
md, Basal segment of mandible.
tg^2 and *tg*^{13}, Part of the terga of the second and thirteenth segments.
cb, Cerebral ganglia supplying the eyes and antennae.
oes, Oesophagus, cut through.
sb.gl, Suboesophageal or first ganglion of ventral chain.
gl^2 and *gl*^{22}, Second and twenty-second ganglia of chain, the posterior nerve of each ganglion, *lg.n*, supplies the leg, the anterior, *tr.n*, the tracheal sac and other organs.
n.gon, Nerve to gonopods.
tr, Tracheal tubes with spiral filament.
tr.s, Tracheal sac.

Eyes are sometimes absent, as in all the genera of Merochaeta and in many genera of other groups, as in *Siphonophora*, one of the Colobognatha, and several of the Juloidea (*Typhloblaniulus*). In other cases they are represented by one or two ocelli on each side (Stemmiuloidea); or by a vertical series of ocelli as in the Glomeroidea and *Polyzonium* amongst the Colobognatha. But in the majority of the orders they are represented by triangular or subspherical aggregations of ocelli recalling in a certain degree those of the Lithobiomorpha amongst the Chilopoda. They are simple in structure and consist externally of a cuticular corneal thickening or lens and internally of a retinular layer of enlarged epidermic cells, the internal or proximal ends of which are continuous with the fibres of the optic nerve. The ovary is unpaired and extends almost the entire length of the body beneath the alimentary canal. The oviducts are sometimes separate tubes (*Lysiopetalum*), sometimes confluent and divided just before terminating in the two orifices behind the base of the legs of the second pair (*Julus*). The testes and seminal ducts occupy the same position and extent as the ovary and oviducts. The ducts are sometimes coiled, sometimes divided, sometimes united. The two testes are sometimes united by transverse branches across the middle line, and are sometimes branched posteriorly They bear short caecal diverticula in which the semen is developed. There are no accessory glands associated with the generative organs; but in some forms, *e.g. Polyxenus*, there is a pair of receptacula seminis extending backwards alongside the ovary and opening into the oviduct.



After Pocock, *J. Linn. Soc.* xxi., Pl. 25.

FIG. 5.—Gonopods of *Trigoniulus andersoni*, one of the Opisthospermophora (Spiroboloidea).

A, Anterior view, and B, lateral views of the apparatus. *ant*, anterior, and *post*, posterior portions of the coleopod ensheathing the phallopod, of which the proximal portion, *ph*, is shown.
C, Phallopod removed from the coleopod.

The secondary sexual characters of the males are of great taxonomic importance. The seminal ducts, like the oviducts, open behind the legs of the second pair. Associated with them in the Limacomorpha (*Glomeridesmus*), there is a pair of very long retractile penes. In the Spirostreptoidea and Juloidea the penes are much shorter and have coalesced. Sometimes they are undeveloped (Spiroboloidea). In other cases, the Merochaeta, Oniscomorpha, &c., the ducts traverse the coxae of the legs of the second pair. But in all these groups, with the exception of the Oniscomorpha, semen is transferred from the genital orifices, with or without the aid of the penes, either into the first or second pairs of appendages of the seventh segment which are modified in various ways, and are termed phallopods. When the posterior legs are so modified the anterior are as a rule even more profoundly altered to form a protective sheath, or coleopod, for the phallopod; and as a further precaution the entire apparatus is usually withdrawn within the seventh segment. In the Oniscomorpha the semen is transferred into a pair of receptacles developed upon the coxae of the legs of the last pair, which are chelate. The male appendages that are modified in the above described ways are comprehensively spoken of as gonopods. Other secondary sexual characters, like the stridulating organs of the males of some Oniscomorpha, the suctorial pads on the legs of Spirostreptoidea, the development of angular processes upon the mandible or first tergal plate, or of fine ridges in the gnathochilarium—all of which are concerned in enabling the male to maintain a secure hold upon the female—are of great taxonomic use in distinguishing the genera and species.

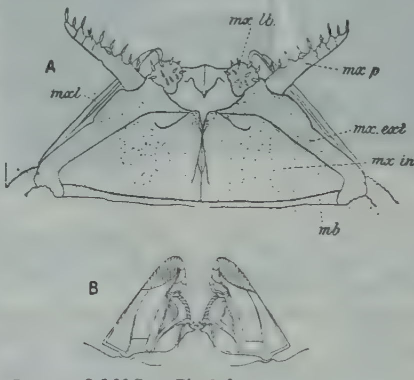
The most important glands in the Diplopoda are the repugnatorial or stink-glands, which, except in the Oniscomorpha, Limacomorpha and Ascospermophora, open by pores upon the sides of more or fewer of the segments. They secrete a fluid with an unpleasant odour, breaking up in one case into cyanide of potassium, and are practically the only means of protection, apart from the hard exoskeleton, which Diplopods possess. In some millipedes silk glands also exist and open upon papillae upon the posterior border of the last tergal plate. They are found in the Ascospermophora, Stemmiuloidea and Proterospermophora, and are used for spinning nests for the eggs and protective cases for the young during exuviation.

Classification.—The existing members of the class Diplopoda may be classified as follows:—

Subclass 1. PSELAPHOGNATHA.
  Order: *Penicillata* (*Polyxenus*).
" 2. CHILOGNATHA.
  Order: *Oniscomorpha* (*Glomeris, Zephronia*).
  " *Limacomorpha* (*Glomeridesmus*).
  " *Colobognatha* (*Polyzonium, Siphonophora*).
  " *Ascospermophora* (*Chordeuma*).
  " *Proterospermophora* (*Lysiopetalum*).
  " *Merochaeta* (*Polydesmus*).
  " *Opisthospermophora*.
    Suborder: Stemmiuloidea (*Stemmiulus*).
    " Spiroboloidea (*Spirobolus*).
    " Spirostreptoidea (*Spirostreptus*).
    " Juloidea (*Julus, Nemasoma*).

Subclass PSELAPHOGNATHA.

Diplopods with the soft integument strengthened by weakly chitinized sclerites and furnished above and on the head with transverse rows of short, stout, somewhat squamiform bristles; laterally, on each side of the principal segments, with a thick tuft of long bristles and with a large, silky, white tuft projecting backwards from the posterior extremity. Mandibles one-jointed. Behind them a pair of small, one-jointed maxillulae, attached to a median membranous "lingua." Behind the "lingua" and maxillulae, a large, double, transverse plate with a long, external sclerite bearing distally in *Polyxenus* an inner short-lobate process and an outer long spiny palpiform branch. The latter, however, is absent in *Lophoproctus*. These sclerites probably represent the gnathochilarium of the Chilognatha, but the homology between the skeletal elements of the jaws in question is not clearly understood. It has been suggested that they represent two pairs of jaws, but embryological proof of this does not exist.



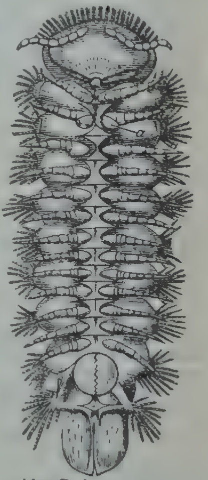
A, after Carpenter, *Q.J.M.S.* 49, Pl. 28, fig. 1.
B, after Latzel, *Die Myr. Ost. Ung. Mon.* II., Pl. ii., 1884.

FIG. 6.—Jaws of *Polyxenus lagurus*.

A, Jaws of second and third pairs. *mxl*, maxillula; *mx.p*, palpiform branch of maxilla; *mx.lb*, lobate process of maxilla; *mx.ext*, external plate of maxilla perhaps corresponding to the stipes of the gnathochilarium of the Chilognatha; *mx.int*, internal plate of maxilla, perhaps corresponding to the mentum and promentum of the gnathochilarium (by Carpenter *mx.int* is regarded as an appendage posterior to the maxilla); *mb*, membrane.
B, Mandibles of *Polyxenus lagurus*.

Order *Penicillata* (= *Ancyrotricha*).

Head large, usually with lateral eyes. Antennae eight-jointed, attached near the middle of the front of the head. On the dorsal side of the body there are eleven segments, simple and compound. The first four of these bear one pair of legs each, the succeeding four two pairs of legs, the ninth segment one pair, making a total of thirteen pairs of legs. The tenth and eleventh or anal segment are legless. There is a narrow sternal area separating the bases of the legs of the two sides. There are no repugnatorial glands. In the male none of the legs are modified as gonopods, but the coxa of each of the legs of the second pair is furnished with a conical penis, which during copulation, it may be supposed, is inserted into the genital orifice of the female, which occupies a corresponding position in that sex. The young when first hatched has only three pairs of legs and five segments. The millipedes of this order are all of small size, measuring at most only a few millimetres in length. The best-known genera are *Polyxenus* and *Lophoproctus*, both of which occur in Europe. Other forms have been discovered in the West Indies, North and South America, and Ceylon; and it is probable that the group has an almost cosmopolitan range. They live under stones or the loosened bark of trees. The carboniferous fossil, *Palaeocampa*, is usually referred to this subclass.



After Bode.

FIG. 7. — Ventral view of *Polyxenus lagurus* much enlarged, actual length a little over $\frac{1}{13}$th of an inch.

a, Position of generative openings.

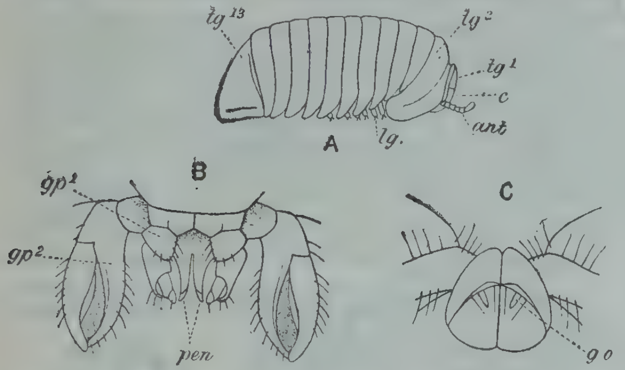
Subclass CHILOGNATHA.

Diplopods with firmly chitinized exoskeleton, sometimes thickly, sometimes sparsely covered with short, simple hairs, but never decorated with tufts or rows of peculiarly modified bristles.

Mandibles, two- or three-jointed; maxillulae absent, the jaws of the second pair being represented by the gnathochilarium described above.

Order *Oniscomorpha.*

Body short and broad, hemispherical in transverse section; convex above, flat below, and capable of being spherically coiled. The exoskeleton of a typical compound segment consists of a vaulted tergum, a pair of free pleural sclerites, two pairs of small tracheal sclerites and two pairs of legs, the latter attached to the ventral membrane, which has no sternal plates. The tergal plates are twelve or thirteen in number, whereof the first is very small, the second enormously expanded laterally, and the last, also enlarged and probably representing at least three segments, extends laterally and posteriorly like a hood over the posterior end of the body without forming a chitinous ring round the anal valves and sternum. In the male the legs of the penultimate pair are sometimes modified as claspers; those of the last pair are always enlarged and prehensile, and bear on their coalesced basal segments a pair of sperm-carrying processes analogous to the phallopods of other groups. Apart from these organs the male has no penis, the seminal ducts perforating the coxae of the legs of the second pair. This order contains two well-marked suborders, the Glomeroidea and the Zephronioidea. The Glomeroidea, comprising the families *Glomeridae, Gervaisiidae, Onomeridae*, have the antennae approximated on the head, the eyes uniserial and twelve (rarely eleven) tergal plates. To this group belong the common pill-millipedes of Europe and North Africa. In North America the *Onomeridae* alone are found. The Zephronioidea, with the single family *Zephroniidae*, have the antennae at the sides of the head, the eyes composed of a spherical cluster of ocelli, and always thirteen tergal plates. This group is common in the tropical and southern continents of the Old World, having representative genera in South Africa, Madagascar, India, Malaysia, Australia and New Zealand. They are much larger forms than the Glomeroidea, large specimens reaching two or three inches in length. In addition to the characters mentioned above the Oniscomorpha differ from all other Diplopods in having long tubular tracheae and the alimentary canal bent upon itself.



After Pocock, in Max Weber's *Zool. Ergebnisse*, &c., IV., Pl. xx.

FIG. 8.—*Sphaeropoeus hercules*, a Sumatran species of the Oniscomorpha.

A, Lateral view of the entire animal. *c*, head; *ant*, antenna; tg^1, tg^2 and tg^{13}, tergal plates of first, second and thirteenth segments; *lg*, extremities of some of the anterior legs.

B, Gonopods of the male. gp^1 and gp^2, anterior and posterior pairs of gonopods, both being chelate claspers; *pen*, processes arising from the basal segments of the gonopods of the second pair, which act as penes.

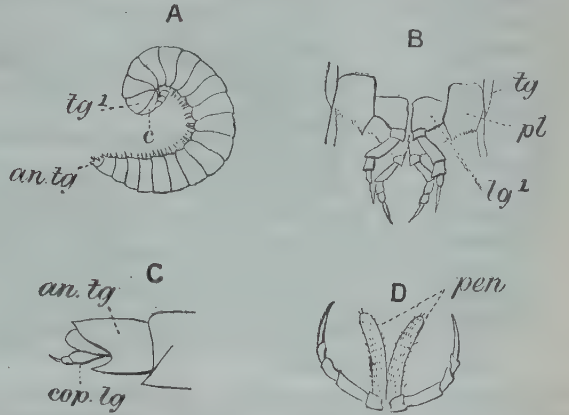
C, Vulvae or genital plates attached to the basal segments of the legs of the second pair in the female. *g.o*, genital orifice.

Order *Limacomorpha.*

Resembling the Oniscomorpha in the shape and structure of a typical segment, except that the tracheal plates are unrepresented; in the facts that the last tergal plate does not form a complete ring round the anal area, and that the last pair of legs in the male are modified; but differing from them in that the body consists of nineteen or twenty segments, is elongate, and tapers anteriorly and posteriorly, the second and last tergal plates being small; in the presence in the male of a pair of long hairy protrusible penes between the legs of the second and third pairs, and in the structure of the gonopods, which, instead of being chelate, terminate in a slender, tapering tarsal segment. This order contains two families: *Zephroniodesmidae* (*Zephroniodesmus*) and *Glomeridesmidae* (*Glomerisdesmus*), the former from tropical Asia, the latter from tropical America. The largest of these millipedes reach a length of only about 7 mm. Nothing special is known of their habits.

Order *Colobognatha.*

Body elongate, capable of being spirally coiled, consisting of a large and indefinite number of segments, each being furnished with a distinct often large sternal area, and with the pleural sclerite or membrane distinct from the tergum. The last tergal plate forms a complete ring round the anal valves. Legs with coxal pouches; those of the seventh segment transformed into gonopods of a very simple type in the male, which is also furnished with a double penis completely or partially confluent with the coxae of the legs of the second pair. Head always small, frequently triangular or piriform, in the latter case the gnathites reduced in size and complexity. Repugnatorial pores present and lateral. The genera of this order are divisible into three families: the *Platydesmidae* (*Platydesmus, Pseudodesmus*), *Polyzonidae* (*Polyzonium, Siphonotus*), *Siphonophoridae* (*Siphonophora*). Of these the *Platydesmidae* have departed least and the *Siphonophoridae* most from the typical Diplopod in the structure of the mouth parts. The group is for the most part tropical, one genus only, *Polyzonium*, extending as far north as Central Europe.



After Pocock, *J. Linn. Soc.* xxiv., Pl. 37.

FIG. 9.—*Glomeridesmus marmoreus*, one of the Limacomorpha.

A, Lateral view. *c*, head with antennae; tg^1, tergal plate of first segment; *an.tg*, tergal plate of last or anal segment.

B, Lower view of one of the segments. *tg*, inferior edge of the tergal plate; *pl*, pleural sclerite; lg^1, basal segment of leg.

C, Posterior extremity of body. *an.tg*, tergal plate of anal segment; *cop.lg*. gonopod or copulatory leg.

D, Legs of the third pair with extruded penes, *pen*, in front of them.

Order *Ascospermophora.*

Body elongate, consisting of from twenty-six to thirty-two segments, but not varying within specific limits; the pleurae coalesced with the terga, the sterna free. More or fewer of the anterior ten pairs of legs may be modified in the males, but no true phallopods are differentiated, the function of seminal receptacles being performed (according to C. Verhoeff) by the exsertile coxal pouches of the two pairs of legs of the eighth segment. The seminal ducts in the male perforate the coxae of the legs of the second pair. There are no repugnatorial pores, and the terga are furnished with three pairs of symmetrically placed hairs or bristles. On the posterior border of the last tergal plate there is a pair of spinning papillae. The millipedes of this order, also called Coelochoeta, are referable to several families: *Chordeumidae* (*Chordeuma*), *Craspedosomidae* (*Craspedosoma*), *Heterochordeumidae* (*Heterochordeuma*), &c. The *Heterochordeumidae* belong to the Oriental region, extending from India to New Zealand. The others are particularly abundant in genera and species in North and Central America and Europe; but are unknown in Africa, south of the Sahara.

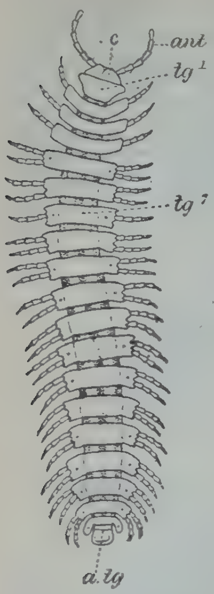
Order *Proterospermophora.*

Differing from the Ascospermophora in that the number of segments is large and variable; they are furnished with repugnatorial pores, and not with the three pairs of setae. In the males the anterior appendages of the seventh segment are modified as phallopods, and the seminal ducts perforate the coxae of the legs of the second pair.

This order, containing the family *Lysiopetalidae* (*Lysiopetalum*), is widely distributed in Europe and North America. Large examples of some of the species, *e.g. L. xanthinum*, reach a length of 4 or 5 ins.

Order *Merochaeta.*

Resembling the Proterospermophora in having only the anterior appendages of the seventh segment converted into phallopods and the seminal ducts perforating the coxae of the second legs in the males; but differing essentially in that the sterna are solidly welded to the rest of the exoskeleton of the segments, which are either nineteen or twenty in number, in the absence of eyes and of spinning papillae, and in having six-jointed legs. This order is cosmopolitan in distribution and consists of a very large number of genera which by some authors are referred to the single family *Polydesmidae*; by others to numerous families. Many species are brightly coloured, and some individuals of the Oriental genus *Platyrhachus* may reach a length of 5 ins. The segments are usually provided with lateral laminate or tubercular expansions bearing the repugnatorial pores, which are only very rarely absent.



After Pocock, in Max Weber's *Zool. Ergebnisse*, &c., IV., Pl. xx.

FIG. 10.

Platyrhachus mirandus, a Sumatran species of *Polydesmidae*, to show the form characteristic of the order Merochaeta.

c,	Head.
ant,	Antenna.
tg^1,	Tergal plate of first body segment.
tg^7,	Ditto of seventh.
a.tg,	Tergal plate of anal segment.

The figure also shows the repugnatorial pores which are present upon the majority of the segments, the laterally expanded tergal plates, and the presence of two pairs of legs for each of the segments except the two last, the four first and the seventh; the latter, since the figured specimen was a male, has the anterior leg converted into a phallopod which is concealed beneath the body.

Order *Opisthospermophora*.

Resembling the Proterospermophora in possessing a large and variable number of segments, each of which, with the exception of the last and the anterior four or five, is furnished with a pair of repugnatorial pores, but differing essentially from them in that the posterior pair of appendages of the seventh segment are converted into phallopods, and the anterior into protective coleopods in the male, and that the seminal ducts in this sex do not perforate the coxae of the legs of the second pair but are usually associated with a distinct penis situated immediately behind them. The genera of this order present greater diversity of structure than is found in the other orders and are referred to four suborders, which by some zoologists are erected to ordinal rank, namely, the Stemmiuloidea (Monochaeta); the Spiroboloidea (Anochaeta); the Spirostreptoidea (Diplochaeta); and the Juloidea (Zygochaeta).

In the Stemmiuloidea the sterna are free and the pleurae partially so; the terminal segment of the legs is bisegmented; there are two pairs of spinning papillae on the last tergite; the penis is a single long tube, and the eyes are represented by one or two large lenses on each side of the head. The genus *Stemmiulus*, constituting the *Stemmiulidae*, is represented by a few species recorded from the Oriental, Ethiopian and Neotropical regions. In the possession of silk-glands this suborder resembles the Ascospermophora and Proterospermophora, and should perhaps rank as an order apart from the Opisthospermophora.

The Spiroboloidea, containing one family, the *Spirobolidae* (*Spirobolus*, *Rhinocricus*, &c.), have the sterna and pleurae coalesced, the tarsi undivided; no spinning papillae, no penis, the eyes represented by an aggregation of ocelli; and the first five segments each with a single pair of legs, the sixth carrying two pairs. This group attains its maximum of development in the tropics, where species and genera are numerous and specimens of large size, *i.e.* 6 ins. or over, are met with.

The Spirostreptoidea resemble the Spiroboloidea in many particulars, but the fourth segment is footless, and the fifth has two pairs of limbs; the male has a distinct and double penis, and in both sexes the stipites of the gnathochilarium extend to the proximal end of the mentum, which is relatively small. The distribution of this order, which contains several families: *Spirostreptidae* (*Spirostreptus*, *Rhynchoproctus*), *Cambalidae* (*Cambala*, *Julomorpha*), &c., is practically the same as that of the Spiroboloidea. Specimens over 6 ins. in length are met with in the tropics of Africa and Asia.

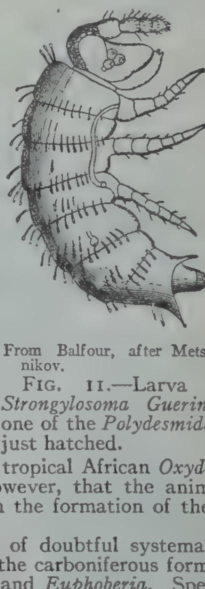
The Juloidea differ from the Spirostreptoidea in having the third segment limbless, the first, second and fourth with a single pair of appendages, and the stipites of the gnathochilarium much expanded and meeting for a considerable distance in the middle line behind the very small promentum.

The best marked family of this group is the *Julidae*, which is widely distributed in the northern hemisphere. Its species and genera (*Julus*, *Pachyiulus*) are abundant in Europe. Another European family, the *Nemasomidae*, is founded for the genus *Nemasoma*, which is remarkable for having the sterna free.

Habits, &c.—Millipedes are principally cryptozoic, living under stones or logs of wood in damp, secluded localities. They feed almost wholly upon decaying vegetable matter, and drink a considerable quantity of water. Some of the tropical species emerge in numbers from their hiding-places after heavy rains, and crawl over the ground and bushes in search of moisture in broad daylight. Their method of progression over level ground is quite peculiar. The body is held in a straight line and is propelled by a succession of wave-like movements of the legs, which are moved in groups, the groups on the right and left side exactly corresponding. Some forms, *e.g. Stemmiulus*, have been described as attempting to evade capture by a hopping action caused by vigorous jerking and wriggling of the body. Many of the species are very conspicuously coloured and the association of brilliant colouring with the existence of the nauseous secretion of the repugnatorial glands suggests that the coloration is aposematic or of warning significance.

Copulation between the sexes takes place before oviposition. In the Opisthospermophora the males and females coil together with the ventral surface of the anterior ends of their bodies opposed, the male holding the female securely by the head while the extended phallopods carrying the semen are brought into contact with her genital orifice. In the *Polydesmidae* pairing is effected in the same way except that the male and female instead of intercoiling remain extended, the male clasping the female with his legs. In the Oniscomorpha the sexes also pair front to front, not head to head, however, but head to tail, so that the gonopods in the anal segment of the male can be applied to the second pair of postoral appendages in the female. Some males of this group, *e.g. Sphaerotherium*, have a stridulating organ on their posterior gonopods and stridulate when finding the females.

The method of disposing of the young, which usually have only three pairs of legs at hatching, differs in various groups. In *Julus* and *Polydesmus* the female burrows below the surface and makes a subspherical nest of small blocks of earth which are moistened with the salivary secretion and moulded to the proper shape between her jaws and anterior legs. When the receptacle is nearly finished she deposits her eggs in it, and, closing the aperture, leaves the whole to its fate. On the other hand, a female specimen of the South African species, *Archispirostreptus erythrocephalus*, that lived in the London Zoological Gardens, buried herself, coiled round the eggs, and remained with her young for some time after they were hatched. Again, millipedes, like the Stemmiuloidea and Ascospermophora, which possess silk-glands, spin silken cases for the protection of their eggs. Immature specimens of these groups spin similar silken cases at the time of exuviation; and cases, resembling the nests, are likewise made for purposes of moulting by immature forms of some exotic species of *Polydesmidae*, *e.g.* by the tropical African *Oxydesmus*. There is good reason to think, however, that the animal makes use of its own voided excrement in the formation of these receptacles.



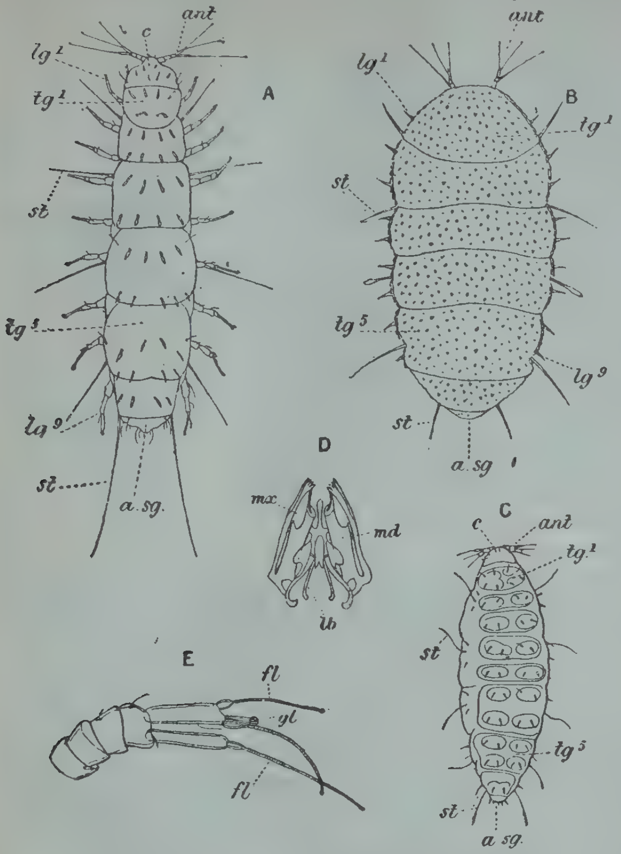
From Balfour, after Metschnikov.

FIG. 11.—Larva of *Strongylosoma Guerinii*, one of the *Polydesmidae*, just hatched.

A considerable number of Chilognatha of doubtful systematic position have been recorded from beds of the carboniferous formation. The best known are *Acantherpestes* and *Euphoberia*. Specimens referred to existing genera have been discovered in amber beds of Oligocene age.

CLASS PAUROPODA.

As in the Diplopoda there is a distinct head bearing a pair of antennae and two pairs of jaws. On each side of the head there is an eye-like spot which may conceivably represent a degenerate eye, although the external cuticle shows no corneal thickening nor the epidermis retinular specialization, and optic nerves are absent from the brain. The antennae are structurally unique in the Arthropoda. There are four short basal segments from the distal of which arise two one-jointed branches, an external thinner and an internal thicker. The external or postaxial branch is tipped with a single long annulate flagelliform bristle with a rounded apical knob; and the internal or preaxial branch with two similar but shorter bristles and a globular, usually pedunculated, sense organ between them. The mandibles or jaws of the first pair are large and one-jointed. Those of the second pair are very short, piriform, and attached to the ventral side of the head by a long, rod-like sclerite. Between these two pairs of jaws there is a horny framework forming a kind of lower lip to the mouth. The correspondence between these mouth parts and those of the Diplopoda is not understood. No doubt the mandibles are homologous in the two groups; but whether the jaws of the second pair in the Pauropoda correspond to the maxillulae of the Pselaphognatha, or to part of the gnathochilarium in the Chilognatha, or whether the chitinous framework alone or in conjunction with the pair of jaws answers to the gnathochilarium are questions to which no answer can as yet be given. Judging from the segmentation and the appendages the body is composed of twelve somites, including the last or anal, which, like the penultimate somite, is limbless. Each somite in front of the penultimate bears a single pair of legs, nine pairs of which are fully developed ambulatory limbs, while those of the first segment are reduced to a pair of bud-like processes. The first and last pairs of ambulatory limbs consist of five segments; in the remaining pairs the terminal segment may be subdivided into two, so that there may be six segments in all. The ambulatory limbs are usually terminated by three claws, a principal and two subsidiary, each claw being accompanied by a membranous pad. Between these limbs, which are relatively longer and stronger than in the Diplopoda and evenly spaced on each side of the body, extends a soft-skinned sternal area. The distensible pleural region of the body is also membranous, but the dorsal area is covered by chitinous plates or terga, usually six in number, excluding that of the anal segment; each of the anterior five of these overlies two limb-bearing somites, the first covering the somite of the rudimentary limbs and of the first pair of locomotor legs, the second those of the second and third pairs of locomotor legs, and so on. This condition is an adumbration of the far completer fusion of somites seen in the Diplopoda. The sixth tergal plate belongs to the limbless penultimate somite. The duplex character of the first five terga is suggested in *Pauropus* by the presence of two rows of sensory bristles; there being only one such row upon the sixth tergum. In the aberrant genus *Brachypauropus* the evidence is practically completed by the correspondence in number between the terga and pairs of legs, there being a divisional line between the two rows of setae. On each side of the body there are five long pubescent tactile setae situated on the second to the sixth terga in *Pauropus*, and on the pleural area corresponding to these terga in *Brachypauropus*.



A and B, after Kenyon, *Tufts Coll. Studies*, iv., 1895; C, after Hansen, *Vid. Meddel.*, 1901, Pl. VI., fig. 3*a*; D. and E, after Kenyon.

FIG. 12.—PAUROPUS.

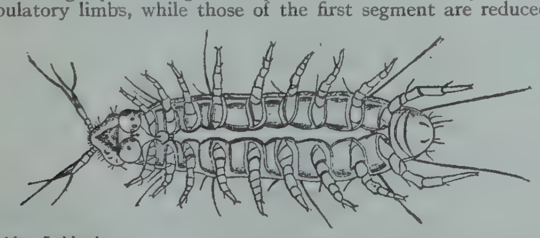
A. *Pauropus huxleyi* (?): *c*, head; *ant.* antenna; tg^1 and tg^5, first and fifth double tergal plates; lg^1, first walking-leg (=2nd post-cephalic appendage); lg^9, ninth walking-leg; *a.sg*, anal segment; *st*, setae.

B. *Eurypauropus spinosus.* Lettering as in A.

C. *Brachypauropus superbus.* Lettering as in A and B; (tg^1) = first and second terga; tg^5, = ninth and tenth terga.

D. Jaws of *Pauropus huxleyi*; *md*, mandible; *mx*, maxilla; *lb*, labial framework.

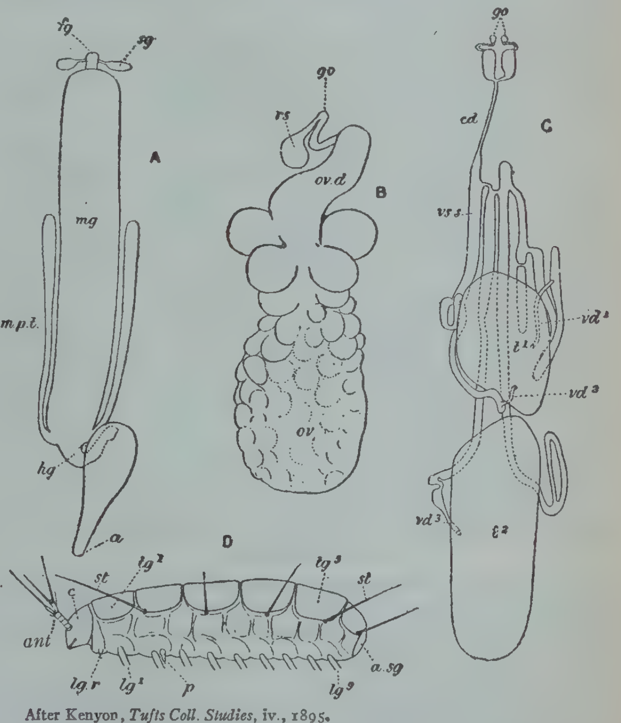
E. Antenna of *Eurypauropus spinosus*; *fl*, flagella; *gl*, sensory organ.



After Lubbock.

FIG. 13.—Enlarged view of *Pauropus huxleyi*, from ventral side.

The cerebral mass of the nervous system is large and when viewed from above is seen to consist of two lobes defined by a median groove. In the absence of eyes no optic nerves are given off. Beneath these are two antennal lobes whence arise, close together, the antennal nerves. Two short commissural cords connect the cerebral mass with the suboesophageal ganglion, a composite mass formed of the nervous centres which supply the two pairs of jaws and the rudimentary legs of the first pair. Behind this large ganglion the cord, which shows superficially no trace of its double origin, presents a ganglionic swelling for each pair of legs. No circulatory or respiratory organs have been detected.



After Kenyon, *Tufts Coll. Studies*, iv., 1895.

FIG. 14.—PAUROPODA.

A. Alimentary canal of *Pauropus*; *fg*, fore-gut; *sg*, salivary gland; *mg*, mid-gut; *hg*, anterior portion of hind-gut; *a*, anus; *m.p.t.*, malpighian tubule.

B. Female genital organs of *Eurypauropus*; *ov*, ovary; *ovid*, oviduct; *rs*, receptaculum seminis; *go*, genital orifice.

C. Male genital organs of *Pauropus*; t^1 and t^2, anterior and posterior portions of testes; vd^1, vd^2, vd^3, vasa deferentia; *vs.s*, vesicula seminalis; *cd*, common duct; *go*, genital orifices.

D. Lateral view of *Pauropus*; *c*, head; *ant.* antenna; tg^1,tg^5, first and fifth tergal plates; *a.sg*, anal segment; *st*, lateral bristles; *lg.r*, rudimentary leg; lg^1 and $lg,^9$ first and ninth fully formed walking legs; *p*, penis.

The alimentary canal consists of a short, narrow fore-gut, a large, straight mid-gut, and a moderately long hind-gut which is itself composed of two parts, an anterior narrow tube which opens into a dilated, piriform, posterior portion, narrowing gradually to terminate in the anus. Opening into the anterior extremity of the fore-gut there is a pair of "salivary" glands. Malpighian tubes have been found in some forms, *i.e.* females of *Eurypauropus spinosus*, but not in any examples, male or female, of *Pauropus huxleyi.* Where present they open at the point of union of the mid-

and hind-guts. The generative organs in the female are very simple, and much like those of the Diplopoda. In the male they are highly complex, and unlike those of any known Arthropod in certain particulars. The wide, unpaired ovary extends nearly to the posterior end of the body. Anteriorly it passes into an oviduct which is unpaired throughout its length. The posterior portion of the duct is wide. The anterior, an abruptly narrowed tube, curves round the nerve-cord and opens by a single sub-median orifice in the third segment. Just within the orifice there opens into the oviduct the short duct of a spherical receptaculum seminis. In the male the testis is never paired. Sometimes it is single, sometimes divided into an anterior and a posterior mass, and sometimes merely constricted. It lies above the intestine in the posterior half of the body in the adult, but at least in the young in some cases, where as many as four divisions have been detected, its position is more lateral. Leading from the sperm masses there may be as many as three slender short ducts which soon expand into wider tubes. These tubes, regarded as seminal vesicles, after forming a complex of loops, coils and caecal prolongations, ultimately unite beneath the intestine in a single tube which passing forwards divides on each side of the alimentary canal to terminate in the two penes situated just behind the bases of the second pair of complete legs, that is to say, the legs of the third segment. Just at the root of the penis there is an accessory gland on the duct, and a little farther back a much larger glandular swelling.

The Pauropoda are divided into three rather sharply defined groups or families which may be briefly characterized as follows:—

Pauropodidae.—Head not covered by the first tergal plate. Anal segment not covered by the sixth tergal plate. Terga of the first ten body segments fused in couples. Tactile setae situated on the lateral portions of the terga which are neither sculptured nor spinous. (*Pauropus, Stylopauropus.*)

Brachypauropodidae.—Head and anal segment free and the terga smooth as in the last; but each of the double terga of the *Pauropodidae* divided into an anterior and posterior plate by a transverse band of membrane and each of these into a pair of plates by a longitudinal integumental strip. The tactile setae arising from the pleural area of the segments. (*Brachypauropus.*)

Eurypauropodidae.—Body wide and onisciform, the head and the anal segment concealed dorsally by the first and penultimate terga respectively. Terga fused as in the *Pauropodidae*, but thickly spinous or sculptured. The tactile setae situated beyond the edge of the terga, as in the *Brachypauropodidae.* (*Eurypauropus.*)

The genus *Pauropus* is probably world-wide in distribution, since it has been discovered in Europe, North and South America, and in Siam. The two known species of *Brachypauropus* were found respectively in Italy and Austria. *Eurypauropus* has representatives in North America and Europe. Examples of *Pauropus* are extremely agile, recalling the centipede *Lithobius* in their movements; those of *Eurypauropus*, on the contrary, are extremely slow and quite comparable in lack of agility to the common pill-millipede. They are usually found in woods, under stones, fallen branches, dead leaves or other damp situations. They are believed to be vegetable feeders and are oviparous. The young upon hatching has four segments and three pairs of legs representing the first three pairs of ambulatory legs of the adult. The two last segments are apodous, the first bears the first pair of legs, and the second the second and third pairs. The young passes through four successive moults, and gradually acquires its full complement of segments and limbs.

CLASS SYMPHYLA.

Prosogoneate Arthropods, differing in many important particulars from the Diplopoda and Pauropoda. The axis of the head lies in the same straight line as that of the body, as in the Chilopoda, and not at right angles to it as in the Diplopoda and Pauropoda. There are no eyes. The antennae are very long and many-jointed. Four pairs of gnathites attached to the under-side of the head have been detected. The first pair (mandibles) are two-jointed, as in many Diplopods. The second pair (maxillulae) are minute, one jointed and articulated to a median lobe or hypopharynx which is supported by two chitinous skeletal rods. The third pair (maxillae) consist of a long, basal segment terminating distally in two lobes; near the distal end of the basal segments there is externally a minute one- or two-jointed process, regarded as a palpus. Between the maxillae lies a large, double plate (labium or maxillae of second pair) which is attached proximally to two rod-like basal segments and terminates distally in two pairs of short lobes. The body is long and narrow and bears on its dorsal side fifteen tergal plates. The first of these, immediately succeeding the head, is very short; the remainder are large and sub-equal in size. The adult animal is furnished with twelve pairs of walking legs, which, with the exception of the first pair, are alike in size and segmentation. Each consists of five segments, the distal of which is long and terminates with two powerful claws. The proximal segment bears internally a slender, cylindrical process which may be termed the parapod. It has been asserted that the segment bearing this parapod is in reality the second and that the true basal segment or coxa is embedded in the ventral integument. The legs of the first and second pairs never have the parapod, but they are invariably present in the remaining ten pairs. The legs of the first pair are never more than four-jointed; they are always smaller than the others, and are sometimes reduced to mere bud-like processes. They belong to the first segment behind the head. The segment represented by the last tergal plate has no ambulatory limbs; but articulated to its posterior border is a pair of large, backwardly directed sclerites, which are perforated by the ducts of two spinning glands. These segments are regarded by some authors as the appendages of the last segment, and have been compared to the cercopods of insects. Attached also to the sides of the last segment in front of the spinning mamilla there is a sub-conical papilla bearing an apical seta arising from a cuplike depression. It has been suggested that these papillae also represent a pair of appendages. In that case the last segment must be double and bear two pairs of appendages. Thus there may be as many as fourteen pairs of trunk appendages. There are, however, only twelve pairs known to exist with certainty. These are represented by as many segments on the ventral side; but are numerically less by two than the terga. It is not known whether this very unusual phenomenon is to be accounted for by the addition of two supernumerary terga or by the excalation of two pairs of appendages. The legs of the first pair are basally in contact; the rest are separated by a triangular sternal area. At the base of the legs, with the exception of those of the first and last pair, there is a slit-like orifice recalling the coxal sacs of certain Diplopoda (*e.g. Lysiopetalum, Platydesmus*). In internal anatomy the Symphyla closely resemble the Diplopoda. The alimentary canal is straight and simple, with a pair of "salivary" glands opening into the fore-gut, and a pair of malpighian tubes joining the hind-gut close to its communication with the mid-gut. There is a dorsal heart with segmental ostia and valves, and also a supraneural vessel. The silk glands, which occur in both sexes, are situated as in *Lysiopetalum.* The generative glands and ducts, which are paired, lie between the alimentary canal above and the normally constructed nerve-cord below, and are accompanied in the male by a pair of seminal vesicles; and the orifice lies ventrally in the third segment behind the head. A peculiarity in which the Symphyla differ from all "tracheate" arthropoda is the presence of a single pair of tracheal tubes opening by a pair of spiracles on the lower surface of the head behind the antennae.

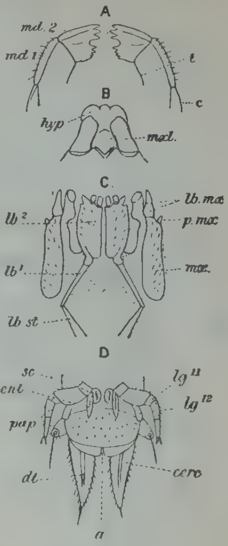


FIG. 15.

After Latzel, *Die Myr. Ost. Ung. Mon.* II. Pl. L. 1884.

A. Mandibles or jaws of first pair of *Scolopendrella*; md^1, md^2, first and second segments; *t*, tendon; *c*, part of ventral skeleton of head.

B. Jaws of second pair; *mxl*, maxillula; *hyp*, hypopharynx.

C. Jaws of third and fourth pairs; *mx*, maxilla; *p.mx*, maxillary palp; *lb.mx*, maxillary lobes; *lb.st*, sternal plate of jaw of fourth pair or labium; lb^1, lb^2, first and second segments of labium. (Figs. A, B, C modified from Hansen, *Q.J.M.S.*, 47, pl. I.)

D. Posterior end of body from below; lg^{11}, leg of 11th pair: lg^{12}, rudimentary leg of 12th pair of immature specimen; *sc*, exsertile sac; *ent.*, parapod; *pap*, sensory papilla; *cerc*, cercus or spinning sclerite: *dl*, duct of silkgland; *a*, anus.

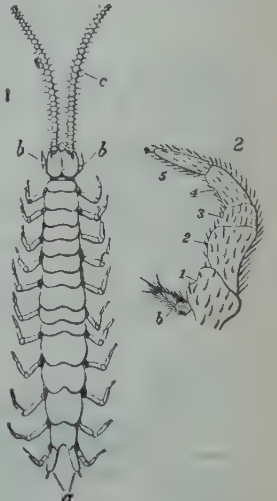

FIG. 16.—1, *Scutigerella sp?* highly magnified (slightly modified from Packard); *a*, spinning sclerites; *b*, *b*, legs of first pair; *c*, antennae.

2, One of the functional legs further enlarged (from Wood Mason), showing the five joints and terminal pair of claws; *b*, parapod.

The newly hatched young has a smaller number of appendages than the adult, the full complement of legs being reached only after successive moults.

The known species of Symphyla are referred to two genera, *Scolopendrella* and *Scutigerella*, which together constitute the family *Scolopendrellidae.* The chief difference between the two lies in the form of the tergal plates, which in *Scolopendrella* have the posterior angles produced and angular, whereas in *Scutigerella* they are rounded. Both genera are widely distributed and are represented, in Europe, South America, Siam, &c. Large specimens reach a limit of between six and seven millimetres. They live in earth, beneath stones, dead leaves or fallen branches, and resemble diminutive centipedes (*Scolopendra* or *Lithobius*) both in appearance and movements. The Symphyla have frequently been compared with the Thysanurous Hexapods, the parapods with their adjacent exsertile vesicles in *Scolopendrella* being very similar to the abdominal appendages and vesicles of such an insect as *Machilis*; while the posterior spinning sclerites or cerci of the former bear much resemblance to the cercopods of *Japyx*. It must be remembered, however, that the spinning glands of certain Diplopods occupy the same position as those of the Symphyla and open upon papilliform processes of the last tergal plate, which are certainly not appendages. Hence, if the papillae are the homologues of the cerci in *Scolopendrella*, these cerci cannot be morphologically comparable to the cercopods of *Japyx* or other insects. But even if the full force of the arguments in favour of relationship between the Symphyla and the Hexapoda be admitted, the Symphyla, nevertheless, differ essentially from the Hexapoda in the anterior position of the generative orifice, and in the presence of twelve pairs of similar ambulatory limbs. (R. I. P.)

MILLOM, a market town in the Egremont parliamentary division of Cumberland, England, in the extreme south-west of the county, on the Furness railway. Pop. of urban district (1901), 10,426. The church of Holy Trinity, Early Norman and Decorated in date, is chiefly of interest for its curious pillars, alternately round and octagonal, and for a window in the north aisle, which has five lights, and is known, on account of its unique shape, as the "fish-window." A massive roodstone stands in the churchyard. Millom Castle, dating from shortly after the Conquest, was fortified in the 14th century by Sir John Huddlestone, whose descendants held it until 1774. For centuries, they exercised the power of life and death; a stone stands where the gallows were formerly erected, and indicates that here they exercised *jura regalia*. Though strongly built, the castle was never of great size, and it has been largely dismantled. A fine carved staircase, however, still exists in the main chapel. In 1648 the Parliamentary forces besieged Millom Castle, and early in the 19th century its park was converted into farmland. In the neighbourhood of Millom there are blast furnaces and highly productive mines of red haematite ore. The deposit lies partly under the foreshore of the river Duddon, and a company has expended upwards of £120,000 upon a sea-wall and embankment to protect the mine from the sea.

MILLS, JOHN (d. 1736), English actor, was a member of the company at Drury Lane from 1695 almost uninterruptedly to the time of his death, playing and creating hundreds of parts. He was at his best in tragedy. His wife was an actress, and their son William—"the younger Mills"—was also an actor of some merit.

MILLS, ROGER QUARLES (1832–), American legislator, was born in Todd county, Kentucky, on the 30th of March 1832. He went to Texas in 1839, studied law, and was admitted to the bar by a special act of the legislature before he was twenty-one. He entered the Confederate army in 1861, took part as a private in the battle of Wilson's Creek, and as colonel commanded the Tenth Texas Infantry at Arkansas Post, Chickamauga (where he commanded a brigade during part of the battle), Missionary Ridge and Atlanta. He served in the national House of Representatives as a Democrat from 1873 to 1892 and in the Senate from 1892 to 1899. He made the tariff his special study, and was long recognized as the leading authority in Congress. As chairman of the Ways and Means Committee of the House of Representatives in 1887–1889 during President Cleveland's first administration, he led the fight for reform. From his committee he reported in April 1888 the "Mills Bill," which provided for a reduction of the duties on sugar, earthenware, glassware, plate glass, woollen goods and other articles, the substitution of *ad valorem* for specific duties in many cases, and the placing of lumber (of certain kinds), hemp, wool, flax, borax, tin plates, salt and other articles on the free list. This bill was passed by the Democratic House on the 21st of July, and was then so amended by a Republican Senate as to be unacceptable to the house. The tariff thus became the chief issue in the presidential campaign of 1888. In 1891 Mills was a candidate in the Democratic caucus for Speaker of the house, but was defeated by Charles F. Crisp (1845–1896) of Georgia. During the free silver controversy he adhered to the Cleveland section of the Democratic party, and failed to be re-elected when his term in the Senate expired in 1899. He then retired to Corsicana, Texas, where he engaged in business and the practice of law.

MILLSTONE GRIT, in geology, a series of massive sandstones, grits and conglomerates with alternate shales, the whole resting directly upon the Carboniferous Limestone or upon intervening shales (Yoredale, Limestone Shales), usually in stratigraphical continuity. Its occasional coal-seams show that conditions of coal-formation had already begun. In Great Britain its outcrop extends from the Bristol Coalfield through South and North Wales to its fullest development in the north-midland counties, Lancashire and Yorkshire, and thence to Scotland, where the Roslin Sandstone of the Lothians and the Moor Rock of Lanark and Stirling are considered its equivalents. Characterized by grits and sandstones of the same general type, though individually variable, as sandbanks formed on the shoaling of the Carboniferous sea, yet often persistent over wide areas, the formation, estimated as 5000 ft. thick in Lancashire, contains typically the following grits in descending order: First, or Rough Rock; second, or Haslingden Flags (Lancashire); third, or Chatsworth Grit (the last two being the Middle Grits of Yorkshire); fourth and fifth, or Kinderscout Grits and the Shale Grits. The first and third, the most persistent, are often coarse and pebbly, like the Kinderscout Grits. In the north of England these grits lose their identity. In South Wales the Millstone Grit, immediately succeeding the Carboniferous Limestone, consists of 450 ft. of grit and shale, its upper member being the massive pebbly Farewell Rock. It extends into the Bristol Coalfield, though not recognized in the Devonshire Culm. In Ireland certain grey grits and flags are assigned to it.

In northern France and Belgium it loses its individuality and is merged in the Coal-measures. It reappears east of the Rhine, but is unrecognizable in the somewhat different Carboniferous succession of eastern Europe. In America the Pottsville Conglomerate, 1500 ft. thick in the south Appalachians, with workable coals, and widely unconformable upon the Mississippian, introduces the Pennsylvanian (Upper Carboniferous) system, and approximately represents the Millstone Grit of western Europe, as does the red conglomerate of Nova Scotia.

The shales of the Millstone Grit include thin beds of marine goniatites (*Glyphioceras bilingue*, *Gastrioceras carbonarium*), *Pterinopecten papyraceus*, and *Lingula mytiloides*, while the grits contain *Lepidodendron*, *Stigmaria* and calamites. In Scotland plants and estuarine fishes differ markedly above and below the Roslin Sandstone.

The English Millstone Grit produces a characteristic scenery of wild moorland plateaux, or alternations of shale-valleys and rugged grit-ridges. The grits furnish valuable building-stones and grindstones. They also afford an excellent water supply. (C. B. W.*)

MILLVILLE, a city of Cumberland county, New Jersey, U.S.A., on the Maurice river, 40 m. S. by E. of Philadelphia. Pop. (1890) 10,002; (1900) 10,583 (598 foreign-born); (1905, state census) 11,884; (1910) 12,451. It is served by the West Jersey & Seashore railway, by electric lines to Philadelphia, Bridgeton, Vineland and Fairton, and by schooners and small freight boats. Peaches and small fruit are cultivated extensively in the surrounding country. In the north part of the city is a large public park, in which a beautiful lake 3 m. long and about 1 m. wide has been formed by damming the river. Glass and moulding sand is found in the vicinity, and the city is engaged principally in the manufacture of glass (especially druggists' ware). The value of the city's factory products increased from $2,513,433 in 1900 to $3,719,417 in 1905, or 48%; and of the total value in 1905, $2,332,614, or 62·7%, was the value of the glass products. Millville was incorporated as a town in 1801, was chartered as a city in 1866, and its charter was revised in 1877.

MILMAN, HENRY HART (1791–1868), English historian and ecclesiastic, third son of Sir Francis Milman, Bart., physician to George III., was born in London on the 10th of November 1791. Educated at Eton and at Brasenose College, Oxford, his university career was brilliant. He gained the Newdigate prize with a poem on the *Apollo Belvidere* in 1812, was elected a fellow of Brasenose in 1814, and in 1816 won the English essay prize with his *Comparative Estimate of Sculpture and Painting*. In 1816 he was ordained, and two years later was presented to the living of St Mary's, Reading. Milman had already made his appearance as a dramatic writer with his tragedy *Fazio* (produced on the stage under the title of *The Italian Wife*). He also wrote *Samor, the Lord of The Bright City*, the subject of which was taken from British legend, the "bright city" being Gloucester; but he failed to invest it with serious interest. In subsequent poetical works he was more successful, notably the *Fall of Jerusalem* (1820) and the *Martyr of Antioch* (1822). The influence of Byron is seen in his *Belshazzar* (1822). A tragedy, *Anne Boleyn*, followed in 1826; and Milman also wrote "When our heads are bowed with woe," and other hymns; an admirable version of the Sanskrit episode of Nala and Damayanti; and translations of the *Agamemnon* of Aeschylus and the *Bacchae* of Euripides. In 1821 he was elected professor of poetry at Oxford, and in 1827 he delivered the Bampton lectures on the character and conduct of the apostles as an evidence of Christianity. His poetical works were published in three volumes in 1839.

Turning to another field, Milman published in 1829 his *History of the Jews*, which is memorable as the first by an English clergyman which treated the Jews as an Oriental tribe, recognized sheikhs and amirs in the Old Testament, sifted and classified documentary evidence, and evaded or minimized the miraculous. In consequence, the author was violently attacked and his inevitable preferment was delayed. In 1835, however, Sir Robert Peel made him rector of St Margaret's, Westminster, and canon of Westminster, and in 1849 he became dean of St Paul's. By this time his unpopularity had nearly died away, and generally revered and beloved, he occupied a dignified and enviable position, which he constantly employed for the promotion of culture and in particular for the relaxation of subscription to ecclesiastical formularies. His *History of Christianity to the Abolition of Paganism in the Roman Empire* (1840) had been completely ignored; but widely different was the reception accorded to the continuation of his work, his great *History of Latin Christianity* (1855), which has passed through many editions. In 1838 he had edited Gibbon's *Decline and Fall of the Roman Empire*, and in the following year published his *Life of Gibbon*. Milman was also responsible for an edition of Horace, and when he died he had almost finished a history of St Paul's Cathedral, which was completed and published by his son, A. Milman (London, 1868), who also collected and published in 1879 a volume of his essays and articles. Milman died on the 24th of September 1868, and was buried in St Paul's Cathedral. By his wife, Mary Ann, a daughter of Lieut.-General William Cockell, he had four sons and two daughters. His nephew, Robert Milman (1816–1876), was bishop of Calcutta from 1867 until his death, and was the author of a *Life of Torquato Tasso* (1850).

See A. C. Tait, *Sermon in Memory of H. H. Milman* (London, 1868), and Arthur Milman, *H. H. Milman* (London, 1900). See also the *Memoirs of R. Milman, bishop of Calcutta*, by his sister, Frances Maria Milman (1879).

MILNE-EDWARDS, HENRY (1800–1885), French zoologist, the son of an Englishman, was born in Bruges on the 23rd of October 1800, but spent most of his life in France. At first he turned his attention to medicine, in which he graduated at Paris in 1823; but his passion for natural history soon prevailed, and he gave himself up to the study of the lower forms of animal life. One of his earliest papers (*Recherches anatomiques sur les crustacés*), which was presented to the Academy of Sciences in 1829, formed the theme of an elaborate and eulogistic report by G. Cuvier in the following year. It embodied the results of two dredging expeditions undertaken by him and his friend J. V. Audouin during 1826 and 1828 in the neighbourhood of Granville, and was remarkable for clearly distinguishing the marine fauna of that portion of the French coast into four zones. Much of his original work was published in the *Annales des sciences naturelles*, with the editorship of which he was associated from 1834. Of his books may be mentioned the *Histoire naturelle de crustacés* (3 vols., 1837–1841), which long remained a standard work; *Histoire naturelle des coralliaires*, published in 1858–1860, but begun many years before; *Leçons sur la physiologie et l'anatomie comparée de l'homme et des animaux* (1857–1881), in 14 volumes; and a little work on the elements of zoology, originally published in 1834, but subsequently remodelled, which enjoyed an enormous circulation. He was appointed in 1841 professor of entomology at the muséum d'histoire naturelle, where twenty-one years later he succeeded Geoffroy Saint-Hilaire in the chair of zoology. The Royal Society in 1856 awarded him the Copley medal in recognition of his zoological investigations. He died in Paris on the 29th of July 1885. His son, Alphonse Milne-Edwards (1835–1900), who became professor of ornithology at the muséum in 1876, devoted himself especially to fossil birds and deep-sea exploration.

MILNER, ALFRED MILNER, Viscount (1854–), British statesman and colonial administrator, was born at Bonn on the 23rd of March 1854, the only son of Charles Milner, M.D., whose wife was a daughter of Major-General Ready, sometime governor of the Isle of Man. His paternal grandfather, an Englishman, settled in Germany and married a German lady; and their son, Charles Milner, practised as a physician in London and became later Reader in English at Tübingen University. Alfred Milner was educated first at Tübingen, then at King's College, London, and under Jowett as a scholar of Balliol College, Oxford, from 1872 to 1876. He graduated in 1877, with a first class in classics, having won the Hertford, Craven, Eldon and Derby scholarships, and was elected to a fellowship of New College. At Oxford he formed a close friendship with Arnold Toynbee, and was associated with his schemes of social work; and subsequently he wrote a tribute to his friend, *Arnold Toynbee: a Reminiscence* (1895). In 1881 he was called to the bar at the Inner Temple and joined the staff of the *Pall Mall Gazette* under John Morley, becoming assistant editor under W. T. Stead. In 1885 he abandoned journalism, and became Liberal candidate for the Harrow division of Middlesex at the general election, but was defeated. He acted as private secretary to Mr (afterwards Lord) Goschen, and in 1887, when Goschen became chancellor of the exchequer, was appointed his principal private secretary. It was by Goschen's influence that in 1889 he was made under-secretary of finance in Egypt. He remained in Egypt four years, his period of office coinciding with the first great reforms, after the danger of bankruptcy had been avoided. Milner returned to England in 1892, and was appointed chairman of the Board of Inland Revenue, being made C.B. in 1894 and K.C.B. in 1895. Shortly after his return to England he published his *England in Egypt*, which at once became the authoritative account of the work done since the British occupation.

Sir Alfred Milner remained at the Board of Inland Revenue until 1897. He was regarded as one of the clearest-headed and most judicious officials in the British service, and his position as a man of moderate Liberal views, who had been so closely associated with Goschen at the Treasury, Cromer in Egypt and Hicks-Beach (Lord St Aldwyn) and Sir W. Harcourt while at the Inland Revenue, marked him out as one in whom all parties might have confidence. The moment for testing his capacity in the highest degree had now come. In April Lord Rosmead resigned his posts of high commissioner for South Africa and governor of Cape Colony. The situation resulting from the Jameson raid (see Transvaal and South Africa) was one of the greatest delicacy and difficulty, and Mr Chamberlain, now colonial secretary, selected Milner as Lord Rosmead's successor. The choice was cordially approved by the leaders of the Liberal party, and warmly recognized at a farewell dinner presided over by Mr Asquith (March 28th, 1897). The appointment was avowedly made in order that an acceptable British statesman, in whom public confidence was reposed, might go to South Africa to consider all the circumstances, and to formulate a policy which should combine the upholding of British interests with the attempt to deal justly with the Transvaal and Orange Free State governments.

Sir Alfred Milner reached the Cape in May 1897, and after the difficulties with President Kruger over the Aliens' Law had been patched up he was free by August to make himself personally acquainted with the country and peoples before deciding on the lines of policy to be adopted. Between August 1897 and May 1898 he travelled through Cape Colony, the Bechuanaland Protectorate, Rhodesia and Basutoland. The better to understand the point of view of the Cape Dutch and the burghers of the Transvaal and Orange Free State, Milner also during this period learned both Dutch and the South African "Taal." He came to the conclusion that there could be no hope of peace and progress in South Africa while there remained the "permanent subjection of British to Dutch in one of the Republics." He also realized—as was shown by the triumphant re-election of Mr Kruger to the presidency of the Transvaal in February 1898—that the Pretoria government would never on its own initiative redress the grievances of the "Uitlanders." In a speech delivered at Graaf Reinet, a Bond stronghold, on the 3rd of March 1898, he made it clear that he was determined to secure freedom and equality for the British subjects in the Transvaal, and he urged the Dutch colonists to induce the Pretoria government to assimilate its institutions, and the temper and spirit of its administration, to those of the free communities of South Africa. The effect of this pronouncement was great, and it alarmed the Afrikanders, who at this time viewed with apprehension the virtual resumption by Cecil Rhodes of his leadership of the Progressive (British) party at the Cape. That Milner had good grounds for his view of the situation is shown in a letter written (March 11) by Mr J. X. Merriman to President Steyn of the Free State: "The greatest danger (wrote Mr Merriman) lies in the attitude of President Kruger and his vain hope of building up a State on a foundation of a narrow unenlightened minority, and his obstinate rejection of all prospect of using the materials which lie ready to his hand to establish a true republic on a broad liberal basis. Such a state of affairs cannot last. It must break down from inherent rottenness." Though this was recognized by the more far-seeing of the Bond leaders, they were ready to support Kruger, whether or not he granted reforms, and they sought to make Milner's position impossible. His difficulties were increased when at the general election in Cape Colony the Bond obtained a majority. Acting strictly in a constitutional manner, Milner thereupon (Oct. 1898) called upon Mr W. P. Schreiner to form a ministry, though aware that such a ministry would be opposed to any direct intervention of Great Britain in the Transvaal. Convinced that the existing state of affairs, if continued, would end in the loss of South Africa by Britain, Milner came to England in November 1898. He returned to the Cape in February 1899 fully assured of the support of Mr Chamberlain, though the government still clung to the hope that the moderate section of the Cape and Free State Dutch would induce Kruger to deal justly with the Uitlanders. He found the situation more critical than when he had left, ten weeks previously. Johannesburg was in a ferment, while General Sir William Butler, who acted as high commissioner in Milner's absence, had allowed it to be seen that he did not take a favourable view of the Uitlander grievances. On the 4th of May Milner penned a memorable despatch to the Colonial Office, in which he insisted that the remedy for the unrest in the Transvaal was to strike at the root of the evil—the political impotence of the injured. "It may seem a paradox," he wrote, "but it is true that the only way for protecting our subjects is to help them to cease to be our subjects." The policy of leaving things alone only led from bad to worse, and "the case for intervention is overwhelming." Milner felt that only the enfranchisement of the Uitlanders in the Transvaal would give stability to the South African situation. He had not based his case against the Transvaal on the letter of the Conventions, and regarded the employment of the word "suzerainty" merely as an "etymological question," but he realized keenly that the spectacle of thousands of British subjects in the Transvaal in the condition of "helots" (as he expressed it) was undermining the prestige of Great Britain throughout South Africa, and he called for "some striking proof" of the intention of the British government not to be ousted from its predominant position. This despatch was telegraphed to London, and was intended for immediate publication; but it was kept private for a time by the home government. Its tenor was known, however, to the leading politicians at the Cape, and at the instance of J. H. Hofmeyr a conference was held (May 31–June 5) at Bloemfontein between the high commissioner and the president of the Transvaal. Milner then made the enactment by the Transvaal of a franchise law which would at once give the Johannesburgers a share in the government of the country his main, and practically his only, demand. The conference ended without any agreement being reached, and the diplomatic discussion which followed (see TRANSVAAL) gradually became more and more contentious. When war broke out, October 1899, Milner rendered the military authorities "unfailing support and wise counsels," being, in Lord Roberts's phrase "one whose courage never faltered."

In February 1901 he was called upon to undertake the administration of the two Boer states, both now annexed to the British Empire, though the war was still in progress. He thereupon resigned the governorship of Cape Colony, while retaining the post of high commissioner. The work of reconstructing the civil administration in the Transvaal and Orange River Colony could only be carried on to a limited extent while operations continued in the field. Milner therefore returned to England to spend a "hard-begged holiday," which was, however, mainly occupied in work at the Colonial Office. He reached London on the 24th of May 1901, had an audience with the king on the same day, was made a G.C.B. and privy councillor, and was raised to the peerage with the title of Baron Milner of St James's and Cape Town. Speaking next day at a luncheon given in his honour, answering critics who alleged that with more time and patience on the part of Great Britain war might have been avoided, he asserted that what they were asked to "conciliate" was "panoplied hatred, insensate ambition, invincible ignorance." Meanwhile the diplomacy of 1899 and the conduct of the war had caused a great change in the attitude of the Liberal party in England towards Lord Milner, whom Mr Leonard Courtney even characterized as "a lost mind." A violent agitation for his recall, in which Sir Henry Campbell-Bannerman joined, was organized, but without success, and in August he returned to South Africa, where he plunged into the herculean task of remodelling the administration. In the negotiations for peace he was associated with Lord Kitchener, and the terms of surrender, signed at Pretoria on the 31st of May 1902, were drafted by him. In recognition of his services he was, on the 15th of July, made a viscount.

Immediately following the conclusion of peace Milner published (June 21) the Letters Patent establishing the system of crown colony government in the Transvaal and Orange River colonies, and exchanging his title of administrator to that of governor. The reconstructive work necessary after the ravages of the war was enormous. He provided a steady revenue by the levying of a tax of 10% on the annual net produce of the gold mines, and devoted special attention to the repatriation of the Boers, land settlement by British colonists, education, justice, the constabulary, and the development of railways. While this work of reconstruction was in progress domestic politics in England were convulsed by the tariff reform movement and Mr Chamberlain's resignation. Milner, who was then spending a brief holiday in Europe, was urged by Mr Balfour to take the vacant post of secretary of state for the colonies. This offer he declined (Oct. 1, 1903), considering it more important to complete his work in South Africa, where economic depression was becoming pronounced. He was back in Johannesburg in December 1903, and had to consider the crisis in the gold-mining industry caused by the shortage of native labour. Reluctantly he agreed, with the assent of the home government, to the proposal of the mineowners to import Chinese coolies on a three years' contract, the first batch of Chinese reaching the Rand in June 1904.

In the latter part of 1904 and the early months of 1905 Lord Milner was engaged on the elaboration of a scheme to provide the Transvaal with a system of "representative" government, a half-way house between crown colony administration and that of self-government. Letters patent providing for representative government were issued on the 31st of March 1905.[1] For some time he had suffered in health from the incessant strain of work, and he determined to retire. He left Pretoria on the 2nd of April and sailed for Europe on the following day. Speaking at Johannesburg on the eve of his departure, he recommended to all concerned the promotion of the material prosperity of the country and the treatment of Dutch and British on an absolute equality. Having referred to his share in the war, he added: "What I should prefer to be remembered by is a tremendous effort subsequent to the war not only to repair the ravages of that calamity but to re-start the colonies on a higher plane of civilization than they have ever previously attained." He left South Africa while the economic crisis was still acute and at a time when the voice of the critic was audible everywhere; but, in the words of the colonial secretary (Mr Alfred Lyttelton) he had in the eight eventful years of his administration "laid deep and strong the foundation upon which a united South Africa would arise to become one of the great states of the empire." On his return home his university honoured him with the honorary degree of D.C.L.

Experience in South Africa had shown him that underlying the difficulties of the situation there was the wider problem of imperial unity. In his farewell speech at Johannesburg he concluded with a reference to the subject. "When we who call ourselves Imperialists talk of the British Empire we think of a group of states bound, not in an alliance—for alliances can be made and unmade—but in a permanent organic union. Of such a union the dominions of the sovereign as they exist to-day are only the raw material." This thesis he further developed in a magazine article written in view of the colonial conference held in London in 1907. He advocated the creation of a permanent deliberative imperial council, and favoured preferential trade relations between the United Kingdom and the other members of the empire; and in later years he took an active part in advocating the cause of tariff reform and colonial preference.

In March 1906 a motion censuring Lord Milner for an infraction of the Chinese labour ordinance, in not forbidding light corporal punishment of coolies for minor offences in lieu of imprisonment, was moved by a Radical member of the House of Commons. On behalf of the Liberal government an amendment was moved, stating that "This House, while recording its condemnation of the flogging of Chinese coolies in breach of the law, desires, in the interests of peace and conciliation in South Africa, to refrain from passing censure upon individuals." The amendment was carried by 355 votes to 135. As a result of this left-handed censure, a counter-demonstration was organized, led by Sir Bartle Frere, and a public address, signed by over 370,000 persons, was presented to Lord Milner expressing high appreciation of the services rendered by him in Africa to the crown and empire.

MILNER, JOSEPH (1744–1797), English evangelical divine, was born at Leeds and educated at Leeds grammar-school and Cambridge. After taking his degree he went to Thorparch, Yorkshire, as curate and assistant schoolmaster. Subsequently he became head master of Hull grammar-school, and in 1768 he was chosen afternoon lecturer at Holy Trinity church, Hull. He became a strong supporter of the evangelical movement of the period, and greatly contributed to its success in Hull. In addition to his work as head master, he took charge of North Ferriby parish, about 9 m. from Hull. His published works include essays and numerous sermons, but his best known work is the *History of the Church of Christ* (London, 1794–1809). He lived to complete the first three volumes, and two more were added by his brother, Isaac Milner (1750–1820), dean of Carlisle, who re-edited the whole work in 1810.

MILNGAVIE (locally pronounced Millguy), a police burgh of Dumbartonshire, Scotland. Pop. (1901), 3481. It lies 6 m. N.N.W. of Glasgow by the North British railway. The chief industries include bleach-fields, dye-works, a distillery and a paper mill; but the town is largely a residential quarter for Glasgow business men. Close to the town are two reservoirs, Mugdock (62 acres) and Craigmaddie (88 acres), in which is stored the water from Loch Katrine. Mugdock Castle, 1¾ m. N. of Milngavie, is an old stronghold of the Grahams; in Baldernock parish, about 2 m. E., stands a cromlech, called "the Auld Wives' Lift" (400 ft. high), commanding a fine view of the lands between the Forth and Clyde. Dougalston Loch, ¾ m. S.E., contains several rare aquatic plants.

MILO, or MILON, of Crotona, Greek athlete, lived about the end of the 6th century B.C. He was six times crowned at the Olympic games and six times at the Pythian for wrestling, and was famous throughout the civilized world for his feats of strength—such as carrying an ox on his shoulders through the stadium at Olympia. In his native city he was much honoured, and he commanded the army which defeated the people of Sybaris in 511. The traditional account of his death is often used to point a moral: he found a tree which some woodcutters had partially split with a wedge, and attempted to rend it asunder; but the wedge fell out, and the tree closed on his hand, imprisoning him till wolves came and devoured him. His name became proverbial for personal strength (Diod. Sic. xii. 9; Pausanias vi. 14; Strabo vi. 263; Herodotus iii. 137).

MILO, TITUS ANNIUS, Roman political agitator, was the son of C. Papius Celsus, but was adopted by his mother's father, T. Annius Luscus. He joined the Pompeian party, and organized bands of mercenaries and gladiators to support the cause by public violence in opposition to P. Clodius, who gave similar support to the democratic cause. Milo was tribune of the plebs in 57 B.C. He took a prominent part in bringing about the recall of Cicero from exile, in spite of the opposition of Clodius. In 53, when Milo was candidate for the consulship and Clodius for the praetorship, the two leaders met by accident on the Appian Way at Bovillae and Clodius was murdered (January 52). Milo was impeached; his guilt was clear, and his enemies took every means of intimidating his supporters and his judges. Cicero was afraid to speak, and the extant *Pro Milone* is an expanded form of the unspoken defence. Milo went into exile at Massilia, and his property was sold by auction. He joined M. Caelius Rufus in 48 in his rising against Caesar, but was slain near Thurii in Lucania. His wife was Fausta, daughter of the dictator Sulla.

MILO OF GLOUCESTER, lord of Brecknock and earl of Hereford (d. 1143), was the son of Walter of Gloucester, who appears as sheriff of that county between 1104 and 1121. Milo succeeded his father about the latter year. He was high in the service of Henry I. between 1130 and 1135, and combined the office of sheriff with that of local justiciar for Gloucestershire. After the death of Henry I. he declared for Stephen, at whose court he appears as constable in 1136. But in 1139, when the empress Matilda appeared in England, he declared for her, and placed the city of Gloucester at her disposal; he was further distinguished by sacking the royalist city of Worcester and reducing the county of Hereford. In 1141, at Matilda's coronation, he was rewarded with the earldom of

---

[1] Owing to the advent of a Liberal ministry in England, December 1905, this scheme remained inoperative (see TRANSVAAL: *History*).

Hereford. He remained loyal to the empress after her defeat at Winchester. John of Salisbury classes him with Geoffrey de Mandeville and others who were *non tam comites regni quam hostes publici.* The charge is justified by his public policy; but the materials for appraising his personal character do not exist.

See the *Continuation of Florence of Worcester* (ed. B. Thorpe, 1848–1849); the Cartulary of Gloucester Abbey (Rolls series); and J. H. Round's *Geoffrey de Mandeville* (1892).

MILORADOVICH, MICHAEL ANDRIJEVICH, Count (1770–1825), Russian general, saw service under Suvarov in the wars against Turkey and Poland, and in the campaign of Italy and Switzerland (1799) earned much distinction as a commander of advanced troops. In 1805, having attained the rank of lieutenant-general, he served under Kutusov in the campaign of Austerlitz, taking part in the actions of Enns and Krems and in the decisive battle of the 2nd of December, in which his column held the Pratzen heights. In the Turkish War he distinguished himself at Giurgevo (1807). Promoted general of infantry in 1810, he commanded a corps at Borodino, and subsequently inflicted the defeat of Tarutino (or Winkovo) on Murat, king of Naples (October 18, 1812). His corps was one of those most active in the pursuit of Napoleon's *Grande Armée*, and in 1813 he led the rear-guard of the Allies after their earlier defeats. At the victory of Kulm he was present in command of a Russian-Prussian corps, which he led at Leipzig and in the campaign of 1814. From 1818 to the time of his death he was military governor of St Petersburg. He perished in the popular outbreak in the capital, on the 26th (14th o.s.) of December 1825.

MILOSH OBRENOVICH I. (1780–1860), prince of Servia, founder of the Obrenovich dynasty, was born in 1780 of poor Servian peasants. When he later became prince of Servia he used to tell how for a penny a day he drove cattle from Servia to Dalmatia. His half-brother, Milan Obrenovich, who had developed into a successful exporter of cattle and pigs into Austria, associated him in his own export trade and otherwise supported him. Partly from gratitude and partly because the family name of his half-brother was already honourably known in the country, Milosh adopted that name as his own, and called himself Obrenovich, instead of Theodorovich. Karageorge, the leader of the first Servian revolution against the Turks, appointed Milosh Obrenovich in 1807 a voyvode, *i.e.* district commander of the national army and civil administrator. As such he distinguished himself in many battles, and was reputed a wise and energetic administrator and a just judge. When in 1813 the Turks under the Grand Vizier Khurshid occupied Servia, and Karageorge and almost all his voyvodes left the country for Austria, Milosh, although strongly advised to follow their example, refused to do so. He remained in the country, surrendered to the Turks, and was recognized by them as the voyvode of Rudnik (Central Servia). As he was then practically the only chief of the nation, the Turks called him to Belgrade, where he was kept through the year 1814 as a hostage. But he found means to prepare a new rising of the Servians against the Turks, and on Palm Sunday 1815 he appeared with his voyvode's standard before the people round the small church of Takovo, and started the second and successful insurrection. Not so much by his victories on the battlefields as by his clever exploitation of the international difficulties of Turkey, and of the known weakness of the Turkish pashas for "baksheesh"—no doubt also by his statesmanlike moderation—he succeeded in less than two years in obtaining from the Porte the practical recognition of the Servian people's right to self-government. The National Assembly in 1817 elected him prince of Servia.

From that year began the organization of Servia by the Servians as an autonomous province of the Ottoman Empire. But its existence as such rested on no safe and legal basis, except on the readiness of the Servians to defend it with all their might and on the goodwill of the sultan and his "Sublime Porte." Milosh therefore worked hard to obtain some sort of international recognition of the semi-independent status of Servia. Russia came to his assistance, and by the Treaty of Adrianople of 1829 the Porte engaged formally to grant Servia full autonomy. This engagement was somewhat developed in the Hatti-sherif of 1830, which added to Servia three districts (Krushevats, Alexinats, Zaechar), acknowledged her full autonomy, recognized Milosh as hereditary prince of Servia, and declared that the Turks in Servia could have properties and live only in fortified places where there were Turkish garrisons, and not in other towns and villages. Milosh won for his family the hereditary right to the throne of Servia without the co-operation of Russia. The creation of a hereditary dynasty in Servia was outside the Russian Balkan policy of that time, and this great and independent success of Milosh was the first cause of Russia's dissatisfaction with him. The second cause was that, yielding to the pressure exercised on him by his own people, he gave the country a constitution without asking "the protector of Servia," the tsar, for his approval of the step. The third cause was that Milosh consistently resented the interference of Russia in the internal affairs of the principality. The climax of his misdeeds, from the Russian point of view, was that on the occasion of his visit to the Sultan Mahmud II. in 1836 he persuaded the British ambassador, Lord Ponsonby, that it would be useful to establish a British consulate in Belgrade. The first British consul in Servia, Colonel Hodges, became speedily an intimate friend of Prince Milosh, who—probably under his new friend's influence—began to agitate to replace the exclusive protectorate of Russia by the joint protectorate of all the great Powers of Europe. The cabinet of St Petersburg now decided to remove Milosh from the throne of Servia, and, supported by the Russian consul-general, the leaders of the Servian opposition, who posed as champions of a constitutional system, succeeded in forcing him to abdicate in 1839. After his abdication Milosh lived mostly on his estates in Rumania, or in Vienna. In December 1858 the National Assembly of Servia, having dethroned Prince Alexander Karageorgevich, recalled Milosh to the throne of Servia. Milosh came, accompanied by his son Michael, and began to reign in his own old fashion; but death closed his activity on the 14th (27th n.s.) of September 1860. He was buried in the cathedral of Belgrade. (C. Mi.)

MILTIADES, the name of two Athenian statesmen and generals of a family (the Philaidae) of Aeginetan origin, which claimed descent from Aeacus.

1. Miltiades (6th century B.C.), the son of Cypselus, a prominent opponent of Peisistratus. According to Herodotus (vi. 36, 37) he led a colony to the Thracian Chersonese at the request of the Doloncians, who, hard pressed by the Absinthians (or Apsinthians), were advised by the Delphian oracle to invite to their country the man who should first show them hospitality after leaving the temple. Since, however, the Athenians had from *c.* 600–590 B.C. held Sigeum in the Troad, whence they had fought against Mitylene, it is probable that the Doloncians appealed for help to Athens, and that Peisistratus took the opportunity of getting rid of one of his chief opponents by sending Miltiades. He became "tyrant" of the Chersonesus, which he fortified by a wall across the isthmus from Cardia to Pactya. He was captured by the people of Lampsacus, but released on the intercession of Croesus of Lydia. He was succeeded by Stesagoras, son of his half-brother, Cimon.

2. Miltiades (died *c.* 488 B.C.), the victor of Marathon, was another son of Cimon. On the death of Stesagoras, he was sent to the Chersonese (? about 518–516) by Hippias—no doubt to support Hegesistratus at Sigeum (see Peisistratus). He entrapped and imprisoned the chief men of Chersonesus, which was then in a turbulent condition, and strengthened himself by an alliance with Hegesipyle, daughter of the Thracian prince Olorus (Herod. vi. 39). He led a contingent in the Scythian expedition of Darius Hystaspis and, according to Herodotus, advised the leaders who were left at the Danube bridge to destroy it and leave Darius to his fate. This story is improbable, as Darius left Miltiades in possession of the Chersonese for some

twenty years longer, though Persian forces were frequently in the neighbourhood. Miltiades was, according to Herodotus, expelled by Scythian invaders, but was brought back by the Doloncians, and subsequently captured Lemnos and Imbros for Athens from the so-called Pelasgian inhabitants, who were Persian dependents. Having thus (probably) incurred the enmity of Darius, Miltiades fled to Athens on the approach of the Persians under Datis and Artaphernes, leaving his son Metiochus a prisoner in Persian hands, and was at once impeached unsuccessfully on the charge of tyranny in the Chersonese.[1] Possibly the story of his having tried to destroy the Danube bridge was invented or exaggerated at this time as an argument in his favour (see Grote, *History of Greece*, 1 vol., ed. 1907, p. 119 note). Since, however, Herodotus almost certainly relied on Alcmaeonid tradition, which was hostile to Miltiades, the whole story is uncertain; the statement that he fled before a Scythian invasion is especially improbable. If Miltiades really recommended the destruction of the bridge, we may infer that the Herodotean story of his flight before the Scythians is a misunderstanding of the fact that his residence in Chersonese after the Scythian invasion was insecure and not continuous.

On the approach of the Persians Miltiades was made one of the ten Athenian generals, and it was on his advice that the polemarch Callimachus decided to give battle at Marathon (*q.v.*). Subsequently he used his influence with the Athenians to induce them to give him a fleet of seventy ships without any indication of his object (Herod. vi. 132–136). Cornelius Nepos (*Miltiades*, c. vii.), probably on good authority (? Ephorus), states that he had a commission to regain control over the Aegean. No doubt his object was to establish an outer line of defence against future Persian aggression. Herodotus says that, having besieged Paros vainly for nearly a month, he made a secret visit to Timo, a priestess of Demeter in Paros, with a view to the betrayal of the island, and being compelled to flee wounded himself severely in attempting to leap a fence (but see Ephorus in *Fragm. hist. gr.* 107).

On his return to Athens he was impeached by Xanthippus, who was allied by marriage to the Alcmaeonids, on the ground that he had "deceived the people," and only escaped on the strength of his past services with a fine of 50 talents. The facts of the trial and the charge are difficult to recover, nor do we know why the siege was raised. Some authorities hold that he was bribed to this course, and hence that the charge was one of treason; others suggest that he retired in the belief that a Persian fleet was approaching. All that is known is that he died of his wound (489–488), without paying the fine, which was paid subsequently by his son Cimon (*q.v.*). He appears to have been a man of strong determination and great personal courage, of a type characteristic of the pre-Cleisthenic constitution. His absence in the Chersonese during the first years of the new democracy (508–493?) and his patrician lineage account naturally for the difference which existed between him and the popular leaders—Themistocles and Aristides.

See the passages of Herodotus and Cornelius Nepos, quoted above, and histories of Greece. On the Parian expedition and the trial, R. W. Macan, *Herodotus iv.–vi.*, vol. 2, appendix xi.; on the foreign policy of Miltiades see THEMISTOCLES. (J. M. M.)

MILTON, JOHN (1608–1674), English poet, was born in Bread Street, Cheapside, London, on the 9th of December 1608. His father, known as Mr John Milton of Bread Street, scrivener, was himself an interesting man. He was a native of Oxfordshire, the son of a Richard Milton, yeoman of Stanton-St-John's, one of the sturdiest adherents to the old Roman Catholic religion in his district, and was educated at Christ Church, Oxford, where he turned Protestant. According to the poet's earliest biographer, John Milton senior was disinherited in the beginning of Queen Elizabeth's reign for reading the Bible. With a good education and good abilities, especially in music, he may have lived for some time in London by musical teaching and practice. Not till 1595, at all events, when he must have been long past the usual age of apprenticeship, do we hear of his preparation for the profession of a scrivener; and not till February 1599–1600, when he was about thirty-seven years of age, did he become a qualified member of the Scriveners' Company. It was then that he set up his "house and shop" at the sign of the Spread Eagle in Bread Street, and began his business of drawing up wills, marriage-settlements, and the like, with such related business as that of receiving money from clients for investment and lending it out to the best advantage. It was at the same time that he married, not, as stated by Aubrey, a lady named Bradshaw, but Sarah Jeffrey, one of the two orphan daughters of a Paul Jeffrey, of St Swithin's, London, "citizen and merchant-taylor," originally from Essex, who had died before 1583. At the date of her marriage she was about twenty-eight years of age. Six children were born to the scrivener and his wife, of whom three survived infancy—Anne, who married Edward Phillips; John, the poet; and Christopher (1615–1693), who was knighted and made a judge under James II.

Life and Works.

The first sixteen years of Milton's life, coinciding exactly with the last sixteen of the reign of James I., associate themselves with the house in Bread Street. His father, while prospering in business, continued to be known as a man of "ingeniose" tastes, and acquired distinction in the London musical world of that time. He contributed a madrigal to Thomas Morley's *Triumph of Oriana* (1601), four motets to Sir William Leighton's *Tears and Lamentations of a Sorrowful Soul* (1614), and some hymn tunes—one of which, "Yor," is still in common use—in Thomas Ravenscroft's *Whole Book of Psalms* (1621). Music was thus a part of the poet's domestic education from his infancy. Again and again Milton speaks with gratitude and affection of the ungrudging pains bestowed by his father on his early education. "Both at the grammar school and also under other masters at home," is the statement in one passage, "he caused me to be instructed daily." When Milton was ten years of age his tutor was Thomas Young (1587–1655), a Scottish divine, who afterwards became master of Jesus College, Cambridge. Young's tutorship lasted till 1622, when he accepted the pastorship of the congregation of English merchants in Hamburg. Already, however, for a year or two his teaching had been only supplementary to the education which the boy was receiving by daily attendance at St Paul's public school, close to Bread Street. The headmaster of the school was Alexander Gill, an elderly Oxford divine, of high reputation for scholarship and teaching ability. Under him, as usher or second master, was his son, Alexander Gill the younger, also an Oxford graduate of scholarly reputation, but of blustering character. Milton's acquaintanceship with this younger Gill, begun at St Paul's school, led to subsequent friendship and correspondence. Far more affectionate and intimate was the friendship formed by Milton at St Paul's with his schoolfellow Charles Diodati, the son of an Italian physician, Dr Theodore Diodati, a naturalized Englishman settled in London, and much respected, both on his own account and as being the brother of the famous Protestant divine, Jean Diodati of Geneva. Young Diodati, who was destined for his father's profession, left the school for Trinity College, Oxford, early in 1623; but Milton remained till the end of 1624. In that year his elder sister, Anne, married Edward Phillips, a clerk in the Government office called the Crown Office in Chancery.

Milton had then all but completed his sixteenth year, and was as scholarly, as accomplished and as handsome a youth as St Paul's school had sent forth. We learn from himself that his exercises "in English or other tongue, prosing or versing, but chiefly this latter," had begun to attract attention even in his boyhood. Of these poems the only specimens that now remain are two copies of Latin verses, preserved in a commonplace book of his (printed by the Camden Society in 1877), and his "Paraphrase on Psalm CXIV" and his "Paraphrase on Psalm CXXXVI." At the age of sixteen years and two months, Milton was entered as a student of Christ's College, Cambridge, in the grade of a "Lesser Pensioner," and he matriculated two months later, on the 9th of April 1625. The master of Christ's was Dr Thomas Bainbrigge; and among the thirteen fellows were Joseph Meade, still remembered as a commentator on the Apocalypse, and William Chappell, afterwards an Irish bishop. It was under Chappell's tutorship that Milton was placed when he first entered the college. At least three students who entered Christ's after Milton, but during his residence, deserve mention. One was Edward King, a youth of Irish birth and high Irish connexions, who entered in 1626, at the age of fourteen, another was John Cleveland, afterwards known as royalist and satirist, who entered in 1627; and the third was Henry More, subsequently famous as the Cambridge Platonist, who entered in 1631, just before Milton left. Milton's own brother, Christopher, joined him in the college in February 1630–1631, at the age of fifteen.

---

[1] So Herodotus; but the story is difficult to believe in view of the fact that the family of Miltiades was distinctively *μισοτύραννος*. Possibly the trial is merely a hostile version of the ordinary test of a man's qualification for office (*δοκιμασία*).

Milton's academic course lasted seven years and five months, bringing him from his seventeenth year to his twenty-fourth. The first four years were his time of undergraduateship. It was in the second of these—the year 1626—that there occurred the quarrel between him and his tutor, Chappell, which Dr Johnson, making the most of a lax tradition from Aubrey, magnified into the supposition that Milton may have been one of the last students in either of the English universities that suffered the indignity of corporal punishment. The legend deserves no credit; but it is certain that Milton, on account of some disagreement with Chappell, left college for a time, though he did not lose his term; and that when he did return, he was transferred from the tutorship of Chappell to that of Nathaniel Tovey. From the first of the Latin elegies one infers that the cause of the quarrel was some outbreak of self-assertion on Milton's part. We learn indeed, from words of his own elsewhere, that it was not only Chappell and Bainbrigge that he had offended by his independent demeanour, but that, for the first two or three years of his undergraduateship, he was generally unpopular, for the same reason, among the younger men of his college. They had nicknamed him "the Lady"—a nickname which the students of the other colleges took up, converting it into "the Lady of Christ's"; and, though the allusion was chiefly to the peculiar grace of his personal appearance, it conveyed also a sneer at what the rougher men thought his unusual prudishness, the haughty fastidiousness of his tastes and morals. A change in this state of things had certainly occurred before January 1628–1629, when, at the age of twenty, he took his B.A. degree. By that time his intellectual preeminence had come to be acknowledged. His reputation for scholarship and literary genius, extraordinary even then, was more than confirmed during the remaining three years and a half of his residence in Cambridge. A fellowship in Christ's which fell vacant in 1630 would undoubtedly have been his had the election to such posts depended then absolutely on merit. As it was, the fellowship was conferred, by royal favour on Edward King, his junior in college standing by sixteen months. In July 1632 Milton completed his career at the university by taking his M.A. degree. Tradition still points out Milton's rooms at Christ's College. They are on the first floor on the first stair on the north side of the great court.

Of Milton's skill at Cambridge, in what Wood calls "the collegiate and academical exercises," specimens remain in his *Prolusiones quaedam oratoriae.* They consist of seven rhetorical Latin essays, generally in a whimsical vein, delivered by him, either in the hall of Christ's College or in the public university schools. To Milton's Cambridge period belong four of his Latin "Familiar Epistles," and the greater number of his preserved Latin poems, including: (1) the seven pieces, written in 1626, which compose his *Elegiarum liber*, two of the most interesting of them addressed to his friend, Charles Diodati, and one to his former tutor, Young, in his exile at Hamburg; (2) the five short Gunpowder Plot epigrams, now appended to the *Elegies*; and (3) the first five pieces of the *Sylvarum liber*, the most important of which are the hexameter poem "In quintum novembris" (1626), and the piece entitled *Naturam non pati senium* (1628). Of the English poems of the Cambridge period the following is a dated list: "On the Death of a fair Infant" (1625–1626), the subject being the death of the first-born child of his sister Anne Phillips; "At a Vacation Exercise in the College" (1628), the magnificent Christmas ode; "On the Morning of Christ's Nativity" (1629); the fragment called "The Passion" and the "Song on May Morning," both probably belonging to 1630; the sonnet "On Shakespeare," certainly belonging to that year, printed in the Shakespeare folio of 1632; the two facetious pieces "On the University Carrier" (1630–1631); the "Epitaph on the Marchioness of Winchester" (1631); the sonnet "To the Nightingale," probably of the same year; the sonnet "On arriving at the Age of twenty-three," dating itself certainly in December 1631.

Just before Milton quitted Cambridge, his father, then verging on his seventieth year, had practically retired from his Bread Street business, leaving the active management of it to a partner, named Thomas Bower, a former apprentice of his, and had gone to spend his declining years at Horton in Buckinghamshire, a small village near Colnbrook, and not far from Windsor. Here, in a house close to Horton church, Milton mainly resided for the next six years—from July 1632 to April 1638.

Although, when he had gone to Cambridge, it had been with the intention of becoming a clergyman, that intention had been abandoned. His reasons were that "tyranny had invaded the church," and that, finding he could not honestly subscribe the oaths and obligations required he "thought it better to preserve a blameless silence before the sacred office of speaking, begun with servitude and forswearing."[1] In other words, he was disgusted with the system which Laud was establishing and maintaining in the Church of England. "Church-outed by the prelates," as he emphatically expresses it, he seems to have thought for a time of the law, but he decided that the only life possible for himself was one dedicated wholly to scholarship and literature. His compunctions on this subject, expressed already in his sonnet on arriving at his twenty-third year, are expressed more at length in an English letter of which two drafts are preserved in Trinity College, Cambridge, sent by him, shortly after the date of that sonnet, and with a copy of the sonnet included, to some friend who had been remonstrating with him on his "belatedness" and his persistence in a life of mere dream and study. There were gentle remonstrances also from his excellent father. Between such a father and such a son, however, the conclusion was easy. What it was may be learnt from Milton's fine Latin poem *Ad patrem.* There, in the midst of an enthusiastic recitation of all that his father had done for him hitherto, it is intimated that the agreement between them on their one little matter of difference was already complete, and that, as the son was bent on a private life of literature and poetry, it had been decided that he should have his own way, and should in fact, so long as he chose, be the master of his father's means and the chief person in the Horton household. For the six years from 1632 this, accordingly, was Milton's position. In perfect leisure, and in a pleasant rural retirement, with Windsor at the distance of an easy walk, and London only about 17 m. off, he went through, he tells us, a systematic course of reading in the Greek and Latin classics, varied by mathematics, music, and the kind of physical science we should now call cosmography.

It is an interesting fact that Milton's very first public appearance in the world of English authorship was in so honourable a place as the second folio edition of *Shakespeare* in 1632. His enthusiastic eulogy on Shakespeare, written in 1630, was one of three anonymous pieces prefixed to that second folio. Among the poems actually written by Milton at Horton the first, in all probability, after the Latin hexameters *Ad patrem*, were the exquisite companion pieces *L'Allegro* and *Il Penseroso.* There followed, in or about 1633, the fragment called *Arcades.* It was part of a pastoral masque performed by the young people of the noble family of Egerton before the countess-dowager of Derby, at her mansion of Harefield, about 10 m. from Horton. That Milton contributed the words for the entertainment was, almost certainly, owing to his friendship with Henry Lawes, who supplied the music. Next in order among the compositions at Horton may be mentioned the three short pieces, "At a Solemn Music," "On Time," and "Upon the Circumcision"; after which comes *Comus*, the largest and most important of all Milton's minor poems. The name by which that beautiful drama is now universally known was not given to it by Milton himself. He entitled it, more simply and vaguely, "A Masque presented at Ludlow Castle, 1634, on Michaelmas night, before John Earl of Bridgewater, Lord President of Wales" (1637). The earl of Bridgewater, the head of the Egerton family, had been appointed president of the council of Wales; among the festivities on his assumption of the office, a great masque was arranged in the hall of Ludlow Castle, his official residence. Lawes supplied the music and was stage manager; he applied to Milton for the poetry; and on Michaelmas night, the 29th of September 1634, the drama furnished by Milton was performed in Ludlow Castle before a great assemblage of the nobility and gentry of the Welsh principality, Lawes taking the part of "the attendant spirit," while the parts of "first brother," "second brother" and "the lady," were taken by the earl's three youngest children, Viscount Brackley, Mr Thomas Egerton and Lady Alice Egerton.

---

[1] See the preface to Book II. of his *Reason of Church Government* (1641–1642), which is of great biographical interest.

From September 1634 to the beginning of 1637 is a comparative blank in our records. Straggling incidents in this blank are a Latin letter of date December 4, 1634, to Alexander Gill the younger, a Greek translation of "Psalm CXIV.," a visit to Oxford in 1635 for the purpose of incorporation in the degree of M.A. in that university, and the beginning in May 1636 of a troublesome lawsuit against his now aged and infirm father. The lawsuit, which was instituted by a certain Sir Thomas Cotton, bart., nephew and executor of a deceased John Cotton, Esq., accused the elder Milton and his partner Bower, or both, of having, in their capacity as scriveners, misappropriated divers large sums of money that had been entrusted to them by the deceased Cotton to be let out at interest.

The lawsuit was still in progress when, on the 3rd of April 1637, Milton's mother died, at the age of about sixty-five. A flat blue stone, with a brief inscription, visible on the chancel-pavement of Horton church, still marks the place of her burial. Milton's testimony to her character is that she was "a most excellent mother and particularly known for her charities through the neighbourhood." The year 1637 was otherwise eventful. It was in that year that his *Comus*, after lying in manuscript for more than two years, was published by itself, in the form of a small quarto of thirty-five pages. The author's name was withheld, and the entire responsibility of the publication was assumed by Henry Lawes. Milton seems to have been in London when the little volume appeared. He was a good deal in London, at all events, during the summer and autumn months immediately following his mother's death. The plague, which had been on one of its periodical visits of ravage through England since early in the preceding year, was then especially severe in the Horton neighbourhood, while London was comparatively free. It was probably in London that Milton heard of the death of Edward King, who had sailed from Chester for a vacation visit to his relatives in Ireland, when, on the 10th of August, the ship in perfectly calm water struck on a rock and went down, he and nearly all the other passengers going down with her. There is no mention of this event in Milton's two Latin "Familiar Epistles" of September 1637, addressed to his friend Charles Diodati, and dated from London; but in November 1637, and probably at Horton, he wrote his matchless pastoral monody of *Lycidas*. It was his contribution to a collection of obituary verses, Greek, Latin and English, inscribed to the memory of Edward King by his numerous friends, at Cambridge and elsewhere. The collection appeared early in 1638. The second part contained thirteen English poems, the last of which was Milton's monody, signed only with his initials "J. M."

Milton was then on the wing for a foreign tour. He had long set his heart on a visit to Italy, and circumstances now favoured his wish. The vexatious Cotton lawsuit, after hanging on for nearly two years, was at an end, as far as the elder Milton was concerned, with the most absolute and honourable vindication of his character for probity, though with some continuation of the case against his partner, Bower. Moreover, Milton's younger brother Christopher, though but twenty-two years of age, and just about to be called to the bar of the Inner Temple, had married; and the young couple had gone to reside at Horton to keep the old man company.

Before the end of April 1638 Milton was on his way across the channel, taking one English man-servant with him. At the time of his departure the last great news in England was that of the National Scottish Covenant. To Charles the news of this "damnable Covenant," as he called it, was enraging beyond measure; but to the mass of the English Puritans it was far from unwelcome, promising, as it seemed to do, for England herself, the subversion at last of that system of "Thorough," or despotic government by the king and his ministers without parliaments, under which the country had been groaning since the contemptuous dissolution of Charles's third parliament ten years before. Through Paris, where Milton received polite attention from the English ambassador, Lord Scudamore, and had the honour of an introduction to the famous Hugo Grotius, then ambassador for Sweden at the French court, he moved on rapidly to Italy, by way of Nice. After visiting Genoa, Leghorn and Pisa, he arrived at Florence, in August 1638. Enchanted by the city and its society, he remained there two months, frequenting the chief academies or literary clubs, and even taking part in their proceedings. Among the Florentines with whom he became intimate were Jacopo Gaddi, founder of an academy called the Svogliati, young Carlo Dati, author of *Vite de' pittori antichi*, Pietro Frescobaldi, Agostino Coltellini, the founder of the Academy of the Apatisti, the grammarian Benedetto Buommattei, Valerio Chimentelli, afterwards professor of Greek at Pisa, Antonio Francini and Antonio Malatesti. It was in the neighbourhood of Florence also that he "found and visited" the great Galileo, then old and blind, and still nominally a prisoner to the Inquisition for his astronomical heresy.[1]

By way of Florence and Siena, he reached Rome some time in October, and spent about another two months there, not only going about among the ruins and antiquities and visiting the galleries, but mixing also, as he had done in Florence, with the learned society of the academies. Among those with whom he formed acquaintance in Rome were the German scholar, Lucas Holstenius, librarian of the Vatican, and three native Italian scholars, named Alessandro Cherubini, Giovanni Salzilli and a certain Selvaggi. There is record of his having dined once, in company with several other Englishmen, at the hospitable table of the English Jesuit College. The most picturesque incident, however, of his stay in Rome was his presence at a great musical entertainment in the palace of Cardinal Francesco Barberini. Here he had not only the honour of a specially kind reception by the cardinal himself, but also, it would appear, the supreme pleasure of listening to the marvellous Leonora Baroni, the most renowned singer of her age.

Late in November he left Rome for Naples. Here he met the aged Giovanni Battista Manso, marquis of Villa (1560–1645), the friend and biographer of Tasso, and subsequently the friend and patron of Marini. He had hardly been in Naples a month, however, when there came news from England which not only stopped an intention he had formed of extending his tour to Sicily and thence into Greece, but urged his immediate return home. "The sad news of civil war in England," he says, "called me back; for I considered it base that, while my fellow-countrymen were fighting at home for liberty, I should be travelling at my ease for intellectual culture" (*Defensio secunda*). In December 1638, therefore, he set his face northwards again. His return journey, however, probably because he learnt that the news he had first received was exaggerated or premature, was broken into stages. He spent a second January and February (1638–1639) in Rome, in some danger, he says, from the papal police, because the English Jesuits in Rome had taken offence at his habit of free speech, wherever he went, on the subject of religion. From Rome he went to Florence, his second visit to the city, including an excursion to Lucca, extending over two months; and not till April 1639 did he take his leave, and proceed, by Bologna and Ferrara, to Venice. About a month was given to Venice; and thence, having shipped for England the books he had collected in Italy, he went on, by Verona and Milan, over the Alps, to Geneva. In this Protestant city he spent a week or two in June, forming interesting acquaintanceships there too, and having daily conversations with the great Protestant theologian Dr Jean Diodati, the uncle of his friend Charles Diodati. From Geneva he returned to Paris, and so to England. He was home again in August 1639, having been absent in all fifteen or sixteen months.

---

[1] This interview forms the subject of one of W. S. Landor's *Imaginary Conversations*.

Milton's Continental tour, and especially the Italian portion of it, which he describes at some length in his *Defensio secunda*, remained one of the chief pleasures of his memory through all his subsequent life. Nor was it without fruits of a literary kind. Besides two of his Latin *Epistolae familiares*, one to the Florentine grammarian Buommattei, and the other to Lucas Holstenius, there have to be assigned to Milton's sixteen months on the Continent his three Latin epigrams *Ad Leonoram Romae canentem*, his Latin scazons *Ad Salsillum poetam romanum aegrotantem*, his fine Latin hexameters entitled *Mansus*, addressed to Giovanni Battista Manso, and his five Italian sonnets, with a canzone, in praise of a Bolognese lady.

His bosom friend and companion from boyhood, Charles Diodati, died in Blackfriars, London, in August 1638, not four months after Milton had gone away on his tour. The intelligence did not reach Milton till some months afterwards, probably not till his second stay in Florence; and, though he must have learnt some of the particulars from his friend's uncle in Geneva, he did not know them fully till his return to England. How profoundly they affected him appears from his *Epitaphium Damonis*, then written in memory of his dead friend. The importance of this poem in Milton's biography cannot be overrated. It is perhaps the noblest of all his Latin poems; and, though written in the artificial manner of a pastoral, it is unmistakably an outburst of the most passionate personal grief. In this respect *Lycidas*, artistically perfect though that poem is, cannot be compared with it; and it is only the fact that *Lycidas* is in English, while the *Epitaphium Damonis* is in Latin, that has led to the notion that Edward King of Christ's College was peculiarly and pre-eminently the friend of Milton in his youth and early manhood.

We should not have known, but for an incidental passage in the *Epitaphium Damonis*, that, at the time of his return from Italy, he had chosen a subject for a great poem from the Arthurian legend. The passage (lines 160–178) is one in which, after referring to the hopes of Diodati's medical career so suddenly cut short by his death, Milton speaks of himself and of his own projects in *his* profession of literature. Milton wrote that he was meditating an epic of which King Arthur was to be the central figure, but which should include somehow the whole cycle of British and Arthurian legend. This epic was to be in English, and he had resolved that all his poetry for the future should be in the same tongue.

Not long after Milton's return the house at Horton ceased to be the family home. Christopher Milton and his wife went to reside at Reading, taking the old gentleman with them, while Milton himself preferred London. He had first taken lodgings in St Bride's Churchyard, at the foot of Fleet Street; but, after a while, probably early in 1640, he removed to a " pretty garden house " of his own, at the end of an entry, in the part of Aldersgate Street which lies immediately on the city side of what is now Maidenhead Court. His sister, whose first husband had died in 1631, had married a Mr. Thomas Agar, his successor in the Crown Office; and it was arranged that her two sons by her first husband should be educated by their uncle. John Phillips, the younger of them, only nine years old, had boarded with him in the St Bride's Churchyard lodgings; and, after the removal to Aldersgate Street, the other brother, Edward Phillips, only a year older, became his boarder also. Gradually a few other boys, the sons of well-to-do personal friends, joined the two Phillipses, whether as boarders or for daily lessons, so that the house in Aldersgate Street became a small private school.

The Arthurian epic had been given up, and his mind was roving among many other subjects, and balancing their capabilities. How he wavered between Biblical subjects and heroic subjects from British history, and how many of each kind suggested themselves to him, one learns from a list in his own handwriting among the Milton MSS. at Cambridge. It contains jottings of no fewer than fifty-three subjects from the Old Testament, eight from the Gospels, thirty-three from British and English history before the Conquest, and five from Scottish history. It is curious that all or most of them are headed or described as subjects for " tragedies," as if the epic form had now been abandoned for the dramatic. There are four separate drafts of a possible tragedy on the Greek model under the title of *Paradise Lost*, two of them merely enumerating the dramatis personae, but the last two indicating the plot and the division into acts. In 1641 he wrote in the *Reason of Church Government* that he was meditating a poem on high moral or religious subjects. But the fulfilment of these plans was indefinitely postponed. Milton became absorbed in the ecclesiastical controversies following on the king's attempt to force the episcopal system on the Scots.

Of the first proceedings of the Long Parliament, including the trial and execution of Strafford, the impeachment and imprisonment of Laud and others, and the breakdown of the system of Thorough by miscellaneous reforms and by guarantees for parliamentary liberty, Milton was only a spectator. It was when the church question emerged distinctly as the question paramount, and there had arisen divisions on that question among those who had been practically unanimous in matters of civil reform, that he plunged in as an active adviser. There were three parties on the church question. There was a high-church party, contending for episcopacy by divine right, and for the maintenance of English episcopacy very much as it was; there was a middle party, defending episcopacy on grounds of usage and expediency, but desiring to see the powers of bishops greatly curtailed, and a limited episcopacy, with councils of presbyters round each bishop, substituted for the existing high episcopacy; and there was the root-and-branch party, as it called itself, desiring the entire abolition of episcopacy and the reconstruction of the English Church on something like the Scottish Presbyterian model. Since the opening of the parliament there had been a storm of pamphlets from these three parties. The manifesto of the high-church party was a pamphlet by Joseph Hall, bishop of Exeter, entitled " Humble Remonstrance to the High Court of Parliament." In answer to Hall, and in representation of the views of the root-and-branch party, there had stepped forth, in March 1640–1641, five leading Puritan parish ministers, the initials of whose names, clubbed together on the title-page of their joint production, made the uncouth word " Smectymnuus." These were Stephen Marshall, Edmund Calamy, Thomas Young, Matthew Newcomen and William Spurstow. Thomas Young was the Scottish divine who had been Milton's tutor in Bread Street; he had returned from Hamburg in 1628, and had been appointed to the vicarage of Stowmarket in Suffolk. The famous Smectymnuan pamphlet in reply to Hall was mainly Young's. What is more interesting is that his old pupil Milton was secretly in partnership with him and his brother-Smectymnuans. Milton's hand is discernible in a portion of the original Smectymnuan pamphlet; and he continued to aid the Smectymnuans in their subsequent rejoinders to Hall's defences of himself. In May 1641 he put forth a defence of the Smectymnuan side in *Of Reformation touching Church Discipline in England and the Causes that hitherto have hindered it.* He reviewed English ecclesiastical history, with an appeal to his countrymen to resume that course of reformation which he considered to have been prematurely stopped in the preceding century, and to sweep away the last relics of papacy and prelacy. Among all the root-and-branch pamphlets of the time it stood out, and stands out still, as the most thorough-going and tremendous. It was followed by four others in rapid succession, —*Of Prelatical Episcopacy and whether it may be deduced from the Apostolical Times* (June 1641), *Animadversions upon the Remonstrant's Defence against Smectymnuus* (July 1641), *The Reason of Church Government urged against Prelaty* (Feb. 1641–1642), *Apology against a Pamphlet called a Modest Confutation of the Animadversions*, &c. (March and April 1641–1642). The first of these was directed chiefly against that middle party which advocated a limited episcopacy, with especial reply to the arguments of Archbishop Ussher, as the chief exponent of the views of that party. Two of the others, as the titles imply, belong to the Smectymnuan series, and were castigations of Bishop Hall. The greatest of the four, and the most important of all Milton's anti-episcopal pamphlets after the first, is that entitled *The Reason of Church Government.* It is there that Milton takes his readers into his confidence, speaking at length of himself and his motives in becoming a controversialist. Poetry, he declares, was his real vocation; it was with reluctance that he had resolved to "leave a calm and pleasing solitariness, fed with cheerful and confident thoughts, to embark in a troubled sea of noises and hoarse disputes"; but duty had left him no option. The great poem or poems he had been meditating could wait; and meanwhile, though in prose-polemics he had the use only of his "left hand," that hand should be used with all its might in the cause of his country and of liberty. The *Apology* was in answer to a *Modest Confutation of a Slanderous and Scurrilous Libel*, the joint work of Hall and his son, attacking Milton's personal character.

The parliament had advanced in the root-and-branch direction so far as to have passed a bill for the exclusion of bishops from the House of Lords, and compelled the king's assent to that bill, when, in August 1642, the further struggle between Charles and his subjects took the form of civil war. The Long Parliament moved on more and more rapidly in the root-and-branch direction, till, by midsummer 1643, the abolition of episcopacy had been decreed, and the question of the future non-prelatic constitution of the Church of England referred to a synod of divines, to meet at Westminster under parliamentary authority. Of Milton's life through those first months of the Civil War little is known. He remained in his house in Aldersgate Street, teaching his nephews and other pupils; and the only scrap that came from his pen was the semi-jocose sonnet bearing the title "When the Assault was intended to the City." In the summer of 1643, however, there was a great change in the Aldersgate Street household. About the end of May, as his nephew Edward Phillips remembered, Milton went away on a country journey, without saying whither or for what purpose; and, when he returned, about a month afterwards, it was with a young wife, and with some of her sisters and other relatives in her company. He had, in fact, been in the very headquarters of the king and the Royalist army in and round Oxford; and the bride he brought back with him was a Mary Powell, the eldest daughter of Richard Powell, of Forest Hill, near Oxford. She was the third of a family of eleven sons and daughters, of good standing, but in rather embarrassed circumstances, and was seventeen years and four months old, while Milton was in his thirty-fifth year. However the marriage came about, it was a most unfortunate event. The Powell family were strongly Royalist, and the girl herself seems to have been frivolous, and entirely unsuited for the studious life in Aldersgate Street. Hardly were the honeymoon festivities over, when, her sisters and other relatives having returned to Forest Hill and left her alone with her husband, she pined for home again and begged to be allowed to go back on a visit. Milton consented, on the understanding that the visit was to be a brief one. This seems to have been in July 1643. Soon, however, the intimation from Forest Hill was that he need not look ever to have his wife in his house again. The resolution seems to have been mainly the girl's own; but, as the king's cause was then prospering in the field, Edward Phillips was probably right in his conjecture that the whole of the Powell family had repented of their sudden connexion with so prominent a Parliamentarian and assailant of the Church of England as Milton. While his wife was away, his old father, who had been residing for three years with his younger and lawyer son at Reading, came to take up his quarters in Aldersgate Street.

Milton's conduct under the insult of his wife's desertion was most characteristic. Always fearless and speculative, he converted his own case into a public protest against the existing law and theory of marriage. *The Doctrine and Discipline of Divorce, Restored to the good of both Sexes from the Bondage of Canon Law and other Mistakes* was the title of a pamphlet put forth by him in August 1643, without his name, but with no effort at concealment, declaring the notion of a sacramental sanctity in the marriage relation to be a clerically invented superstition, and arguing that inherent incompatibility of character, or contrariety of mind, between two married persons is a perfectly just reason for divorce. If the date, the 1st of August, is correct, the pamphlet must have been written almost immediately on his wife's departure and before her definite refusal to return. There was no reference to his own case, except by implication; but the boldness of the speculation roused attention and sent a shock through London. It was a time when the authors of heresies of this sort, or of any sort, ran considerable risks. The famous Westminster Assembly of Divines, called by the Long Parliament, met on the 1st of July 1643. Whether Milton's divorce tract was formally discussed in the Assembly during the first months of its sitting is unknown; but it is certain that the London clergy, including not a few members of the Assembly, were then angrily discussing it in private. That there might be no obstacle to a more public prosecution, Milton put his name to a second and much enlarged edition of the tract, in February 1644, dedicated openly to the parliament and the assembly. Then, for a month or two, during which the gossip about him and his monstrous doctrine was spreading more and more, he turned his attention to other subjects.

Among the questions in agitation in the general ferment of opinion brought about by the Civil War was that of a reform of the national system of education and especially of the universities. To this question Milton made a contribution in June 1644, in a small treatise, *Of Education*, in the form of a letter to Samuel Hartlib, a German then resident in London and interesting himself busily in all philanthropic projects and schemes of social reform. In the very next month, however, July 1644, he returned to the divorce subject in a pamphlet addressed specially to the clergy and entitled *The Judgment of Martin Bucer concerning Divorce.* The outcry against him then reached its height. He was attacked in pamphlets; he was denounced in pulpits all through London, and especially by Herbert Palmer in a sermon preached on the 13th of August, before the two Houses of Parliament; strenuous efforts were made to bring him within definite parliamentary censure. In the cabal formed against him for this purpose a leading part was played, at the instigation of the clergy, by the Stationers' Company of London, which had a plea of its own against him on the ground that his doctrine was not only immoral, but had been put forth in an illegal manner. His first divorce treatise, though published immediately after the "Printing Ordinance" of the parliament of the 14th of June 1643, requiring all publications to be licensed for press by one of the official censors, and to be registered in the books of the Stationers' Company, had been issued without license and without registration. Complaint to this effect was made against Milton, with some others liable to the same charge of contempt of the printing ordinance, in a petition of the Stationers of the House of Commons in August 1644; and the matter came before committee both in that House and in the Lords.

It is to this circumstance that the world owes the most popular and eloquent, if not the greatest, of all Milton's prose writings, his famous *Areopagitica, a Speech of Mr John Milton for the Liberty of Unlicensed Printing, to the Parliament of England.* It appeared on the 25th of November 1644, deliberately unlicensed and unregistered, and was a remonstrance addressed to the parliament, as if in an oration to them face to face, against their ordinance of June 1643 and the whole system of licensing and censorship of the press. Nobly eulogistic of the parliament in other respects, it denounced their printing ordinance as utterly unworthy of them, and of the new era of English liberties which they were initiating, and called for its repeal. Though that effect did not follow, the pamphlet virtually accomplished its purpose. The licensing system had received its death-blow; and, though the Stationers returned to the charge in another complaint to the House of Lords, Milton's offence against the press ordinance was condoned. He was still assailed in pamphlets, and found himself "in a world of disesteem"; but he lived on through the winter of 1644/5 undisturbed in his house in Aldersgate Street. To this period there belong, in the shape of verse, only his sonnets ix. and x., the first to some anonymous lady, and the second "to the Lady Margaret Ley," with perhaps the Greek lines entitled *Philosophus ad regem quendam.* His divorce speculation, however, still occupied him; and in March 1644/5 he published simultaneously his *Tetrachordon: Expositions upon the four chief places of Scripture which treat of Marriage*, and his *Colasterion, a Reply to a nameless Answer against the Doctrine and Discipline of Divorce.* In these he replied to his chief recent assailants, lay and clerical, with merciless severity.

Through the latter part of 1644, Milton had been saved from the penalties which his Presbyterian opponents would have inflicted on him by the general championship of liberty of opinion by Cromwell and the army Independents. Before the middle of 1645 he, with others who were on the black books of the Presbyterians as heretics, was safer still. Milton's position after the battle of Naseby may be easily understood. Though his first tendency on the Church question had been to some form of a Presbyterian constitution for the Church, he had parted utterly now from the Scots and Presbyterians, and become a partisan of Independency, having no dread of "sects and schisms," but regarding them rather as healthy signs in the English body-politic. He was, indeed, himself one of the most noted sectaries of the time, for in the lists of sects drawn out by contemporary Presbyterian writers special mention is made of one small sect who were known as *Miltonists* or *Divorcers.*

So far as Milton was concerned personally, his interest in the divorce speculation came to an end in July or August 1645, when, by friendly interference, a reconciliation was effected between him and his wife. The ruin of the king's cause at Naseby had suggested to the Powells that it might be as well for their daughter to go back to her husband after their two years of separation. It was not, however, in the house in Aldersgate Street that she rejoined him, but in a larger house, which he had taken in the adjacent street called Barbican, for the accommodation of an increasing number of pupils.

The house in Barbican was tenanted by Milton from about August 1645 to September or October 1647. Among his first occupations there must have been the revision of the proof sheets of the first edition of his collected poems. It appeared as a tiny volume, copies of which are now very rare, with the title, *Poems of Mr John Milton, both English and Latin, compos'd at several times. Printed by his true Copies. The songs were set in Musick by Mr Henry Lawes. . . .* The title-page gives the date 1645, but the 2nd of January 1645/6 seems to have been the exact day of its publication. Whether because his pedagogic duties now engrossed him or for other reasons, very few new pieces were added in the Barbican to those that the little volume had thus made public. In English, there were only the four sonnets now numbered xi.–xiv., the first two entitled "On the Detraction which followed upon my writing certain Treatises," the third "To Mr Henry Lawes on his Airs," and the fourth "To the Religious Memory of Mrs Catherine Thomson," together with the powerful anti-Presbyterian invective or "tailed sonnet" entitled "On the New Forcers of Conscience under the Long Parliament"; and in Latin there were only the ode *Ad Joannem Rousium*, the *Apologus de Rustico et Hero*, and one interesting "Familiar Epistle" (April 1647) addressed to his Florentine friend Carlo Dati.

Some family incidents of importance belong to this time of residence in Barbican. The fall of Oxford in 1646 compelled the whole of the Powell family to seek refuge in London, and most of them found shelter in Milton's house. His first child, a daughter named Anne, was born there on the 29th of July that year; on the 1st of January 1646/7 his father-in-law Richard Powell died there, leaving his affairs in confusion; and in the following March his own father died there, at the age of eighty-four, and was buried in the adjacent church of St Giles, Cripplegate.

From Barbican Milton removed, in September or October 1647, to a smaller house in that part of High Holborn which adjoins Lincoln's Inn Fields. His Powell relatives had now left him, and he had reduced the number of his pupils, or perhaps kept only his two nephews. But, though thus more at leisure, he did not yet resume his projected poem, but occupied himself rather with three works of scholarly labour which he had already for some time had on hand. One was the compilation in English of a complete history of England, or rather of Great Britain, from the earliest times; another was the preparation in Latin of a complete system of divinity, drawn directly from the Bible; and the third was the collection of materials for a new Latin dictionary. Milton had always a fondness for such labours of scholarship and compilation. Of a poetical kind there is nothing to record, during his residence in High Holborn, but an experiment in psalm-translation, in the shape of Ps. lxxx.–lxxxviii. done into service-metre in April 1648, and the sonnet to Fairfax, written in September of the same year.

The crushing defeat of the Scottish army by Cromwell in the three days' battle of Preston (1648) and the simultaneous suppression of the English Royalist insurrection in the south-east counties by Fairfax's siege and capture of Colchester, left King Charles at the mercy of the victors. Milton's sonnet "On the Lord General Fairfax, at the siege of Colchester," attested the exultation of the writer at the triumph of the parliamentary cause. His exultation continued through what followed. When the king was beheaded (1649) the first Englishman of mark out of parliament to attach himself openly to the new republic was John Milton. This he did by the publication of his pamphlet entitled "Tenure of Kings and Magistrates, proving that it is lawful, and hath been held so in all ages, for any who have the power, to call to account a Tyrant or wicked King, and, after due conviction, to depose and put him to death, if the ordinary Magistrate have neglected or denied to do it." It was out within a fortnight after the king's death, and was Milton's last performance in the house in High Holborn. The chiefs of the new republic could not but perceive the importance of securing the services of a distinguished man who had so opportunely and so powerfully spoken out in favour of their tremendous act. In March 1649, accordingly, Milton was offered, and accepted, the secretaryship for foreign tongues to the council of state of the new Commonwealth. The salary was to be £288 a year (worth about £1000 a year now). To be near his new duties in attendance on the council, which held its daily sittings for the first few weeks in Derby House, close to Whitehall, but afterwards regularly in Whitehall itself, he removed at once to temporary lodgings at Charing Cross. In the very first meetings of council which Milton attended he must have made personal acquaintance with President Bradshaw, Fairfax, Cromwell himself, Sir Henry Vane, Whitelocke, Henry Marten, Haselrig, Sir Gilbert Pickering and the other chiefs of the council and the Commonwealth, if indeed he had not known some of them before. After a little while, for his greater convenience, official apartments were assigned him in Whitehall itself.

At the date of Milton's appointment to the secretaryship he was forty years of age. His special duty was the drafting in Latin of letters sent by the council of state, or sometimes by the Rump Parliament, to foreign states and princes, with the examination and translation of letters in reply, and with personal conferences, when necessary, with the agents of foreign powers in London, and with envoys and ambassadors. As Latin was the language employed in the written diplomatic documents, his post came to be known indifferently as the secretaryship for foreign tongues or the Latin secretaryship. In that post, however, his duties, more particularly at first, were very light in comparison with those of his official colleague, Walter Frost, the general secretary. Foreign powers held aloof from the English republic as much as they could; and, while Frost had to be present in every meeting of the council, keeping the minutes, and conducting all the general correspondence, Milton's presence was required only when some piece of foreign business turned up. Hence, from the first, his employment in very miscellaneous work. Especially, the council looked to him for everything in the nature of literary vigilance and literary help in the interests of the struggling Commonwealth. He was employed in the examination of suspected papers, and in interviews with their authors and printers; and he executed several great literary commissions expressly entrusted to him by the council. The first of these was his pamphlet entitled *Observations on the Articles of Peace* (between Ormonde and the Irish). It was published in May 1649, and was in defence of the republic against a complication of Royalist intrigues and dangers in Ireland. A passage of remarkable interest in it is one of eloquent eulogy on Cromwell. More important still was the *Eikonoklastes* (which may be translated "Image-Smasher"), published by Milton in October 1649, by way of counterblast to the famous *Eikon Basilike* ("Royal Image"), which had been in circulation in thousands of copies since the king's death, and had become a kind of Bible in all Royalist households, on the supposition that it had been written by the royal martyr himself (see GAUDEN, JOHN). In the end of 1649 there appeared abroad, under the title of *Defensio regia pro Carolo I.*, a Latin vindication of the memory of Charles, with an attack on the English Commonwealth. As it had been written, at the instance of the exiled royal family, by Salmasius, or Claude de Saumaise, of Leiden, then of enormous celebrity over Europe as the greatest scholar of his age, it was regarded as a serious blow to the infant Commonwealth. Milton threw his whole strength into a reply through the year 1650, interrupting himself only by a new and enlarged edition of his *Eikonoklastes.* His Latin *Pro populo anglicano defensio* (1651), ran at once over the British Islands and the Continent, and was received by scholars as an annihilation of Salmasius. Through the rest of 1651 the observation was that the two agencies which had co-operated most visibly in raising the reputation of the Commonwealth abroad were Milton's books and Cromwell's battles.

Through the eventful year 1651, in addition to the other duties of his secretaryship, Milton acted as licenser and superintending editor of the *Mercurius politicus*, a newspaper issued twice a week, of which Marchamont Nedham was the working editor and proprietor. Milton's hand is discernable in some of the leading articles.

About the end of 1651 Milton left his official rooms in Whitehall for a "garden house" he had taken on the edge of St James's Park in what was then called Petty France, Westminster, but is now York Street. The house, afterwards 19 York Street, was occupied by James Mill and William Hazlitt in succession, and was not pulled down till 1877. Milton had now more to do in the special work of his office, in consequence of the increase of correspondence with foreign powers. But he had for some time been in ailing health; and a dimness of eyesight which had been growing upon him gradually for ten years had been settling rapidly, since his labour over the answer to Salmasius, into total blindness. Before or about May 1652, when he was but in his forty-fourth year, his blindness became total, and he could go about only with some one to lead him. Hence a rearrangement of his secretarial duties. Such of these duties as he could perform at home, or by occasional visits to the Council Office near, he continued to perform; but much of the routine work was done for him by an assistant, a well-known German, George Rudolph Weckherlin, succeeded later by Philip Meadows and, eventually, by Andrew Marvell. Precisely to this time of a lull in Milton's secretaryship on account of his ill-health and blindness we have to refer his two great companion sonnets "To the Lord General Cromwell" and "To Sir Henry Vane the Younger."

In 1652 died his only son, who had been born at Whitehall in the March of the preceding year. His wife died in 1653/4, just after she had given birth to his third daughter, Deborah. With the three children thus left him—Anne, but six years old, Mary, not four, and the infant Deborah—the blind widower lived on in his house in Petty France in such desolation as can be imagined. He had recovered sufficiently to resume his secretarial duties; and the total number of his dictated state letters for the single year 1652 is equal to that of all the state letters of his preceding term of secretaryship put together. To the same year there belong also three of his Latin "Familiar Epistles." In December 1652 there was published *Joannis Philippi Angli responsio ad apologiam anonymi cujusdam tenebrionis*, being a reply by Milton's younger nephew, John Phillips, but touched up by Milton himself, to one of several pamphlets that had appeared against Milton for his slaughter of Salmasius.

In December 1653 Cromwell's formal sovereignty began under the name of the Protectorate, passing gradually into more than kingship. This change from Government by the Rump and its council to government by a single military lord protector and his council was regarded by many as treason to the republican cause, and divided those who had hitherto been the united Commonwealth's men into the "Pure Republicans," represented by such men as Bradshaw and Vane, and the "Oliverians," adhering to the Protector. Milton, whose boundless admiration of Cromwell had shown itself already in his Irish tract of 1649 and in his recent sonnet, was recognized as one of the Oliverians. He remained in Oliver's service and was his Latin secretary through the whole of the Protectorate. For a while, indeed, his Latin letters to foreign states in Cromwell's name were but few—Thurloe, as general secretary, officiating as Oliver's right-hand man in everything, with a Philip Meadows under him, at a salary of £200 a year, as deputy for the blind Milton in foreign correspondence and translations. The reason for this temporary exemption of Milton from routine duty may have been that he was then engaged on an answer to the pamphlet from the Hague entitled *Regii sanguinis clamor ad coelum adversus parricidas anglicanos* (March 1652). Salmasius was now dead, and the Commonwealth was too stable to suffer from such attacks; but no Royalist pamphlet had appeared so able or so venomous as this in continuation of the Salmasian controversy. All the rather because it was in the main a libel on Milton himself did a reply from his pen seem necessary. It came out in May 1654, with the title *Joannis Miltoni Angli pro populo anglicano defensio secunda* (Second Defence of John Milton, Englishman, for the People of England). The author of *Regii sanguinis clamor* was Dr Peter du Moulin the younger, a naturalized French Presbyterian minister, then moving about in English society, close to Milton; but, as that was a profound secret, and the work was universally attributed on the Continent to an Alexander More or Morus, a French minister of Scottish descent then a professor at Middelburg, who had certainly managed the printing in consultation with the now deceased Salmasius, and had contributed some portion of the matter—Milton made More the responsible person and the one object of his invective. The savage attack on More's personal character, however, is but part of the *Defensio secunda.* It contains passages of singular autobiographical and historical value, and includes laudatory sketches of such eminent

Commonwealth's men as Bradshaw, Fairfax, Fleetwood, Lambert and Overton, together with a long panegyric on Cromwell himself and his career, which remains to this day unapproached for elaboration and grandeur by any estimate of Cromwell from any later pen.

From about the date of the publication of the *Defensio secunda* to the beginning of 1655 the only specially literary relics of Milton's life are his translations of Ps. i.–viii. in different metres, done in August 1654, his translation of Horace's *Ode*, i. 5, done probably about the same time, and two of his Latin "Familiar Epistles." The most active time of his secretaryship for Oliver was from April 1655 onwards. In that month, in the course of a general revision of official salaries under the Protectorate, Milton's salary of £288 a year hitherto was reduced to £200 a year, with a kind of redefinition of his office, recognizing it, we may say, as a Latin secretaryship extraordinary. Philip Meadows was to continue to do all the ordinary Foreign Office work, under Thurloe's inspection; but Milton was to be called in on special occasions. Hardly was the arrangement made when a signal occasion did occur. In May 1655 all England was horrified by the news of the massacre of the Vaudois Protestants (Waldenses) by the troops of Emanuele II., duke of Savoy and prince of Piedmont, in consequence of their disobedience to an edict requiring them either to leave their native valleys or to conform to the Catholic religion. Cromwell and his council took the matter up with all their energy; and the burst of indignant letters on the subject despatched in that month and the next to the duke of Savoy himself, Louis XIV. of France, Cardinal Mazarin, the Swiss cantons, the states-general of the United Provinces, and the kings of Sweden and Denmark, were all by Milton. His famous sonnet "On the Late Massacre in Piedmont" was his more private expression of feeling on the same occasion. This sonnet was in circulation, and the case of the Vaudois Protestants was still occupying Cromwell, when, in August 1655, there appeared the last of Milton's Latin pamphlets. It was his *Pro se defensio* . . . in answer to an elaborate self-defence which More had put forth on the Continent since Milton's attack on his character. In that year also appeared Milton's *Scriptum domini protectoris . . . contra hispanos.*

Through the rest of Cromwell's Protectorate, Milton's life was of comparatively calm tenor. He was in much better health than usual, bearing his blindness with courage and cheerfulness; he was steadily busy with important despatches to foreign powers on behalf of the Protector, then in the height of his great foreign policy; and his house in Petty France seems to have been, more than at any previous time since the beginning of his blindness, a meeting-place for friends and visitors, and a scene of pleasant hospitalities. The four sonnets now numbered xix.–xxii., one of them to young Lawrence, the son of the president of Cromwell's council, and two of the others to Cyriack Skinner, once his pupil, belong to this time of domestic quiet, as do also no fewer than ten of his Latin "Familiar Epistles." His marriage with Katherine Woodcock on the 12th of November 1656 brought him a brief period of domestic happiness; but, after only fifteen months, he was again a widower, by her death in childbirth in February 1657/8. The child dying with her, only the three daughters by the first marriage remained. The touching sonnet which closes the series of Milton's *Sonnets* is his sacred tribute to the memory of his second marriage and to the virtues of the wife he had so soon lost. Even after that loss we find him still busy for Cromwell. Andrew Marvell, in September 1657 succeeded Meadows, much to Milton's satisfaction, as his assistant secretary; but this had by no means relieved him from duty. Some of his greatest despatches for Cromwell, including letters, of the highest importance, to Louis XIV., Mazarin and Charles Gustavus of Sweden, belong to the year 1658.

There is, unfortunately, no direct record to show what Cromwell thought of Milton; but there is ample record of what Milton thought of Cromwell. "Our chief of men," he had called Cromwell in his sonnet of May 1652; and the opinion remained unchanged. He thought Cromwell the greatest and best man of his generation, or of many generations; and he regarded Cromwell's assumption of the supreme power, and his retention of that power with a sovereign title, as no real suppression of the republic, but as absolutely necessary for the preservation of the republic, and for the safeguard of the British Islands against a return of the Stuarts. Nevertheless, under this prodigious admiration of Cromwell, there were political doubts and reserves. Milton was so much of a modern radical of the extreme school in his own political views and sympathies that he cannot but have been vexed by the growing conservatism of Cromwell's policy through his Protectorate. To his grand panegyric on Oliver in the *Defensio secunda* of 1654 he had ventured to append cautions against self-will, over-legislation and over-policing; and he cannot have thought that Oliver had been immaculate in these respects through the four subsequent years. The attempt to revive an aristocracy and a House of Lords, on which Cromwell was latterly bent, cannot have been to Milton's taste. Above all, Milton dissented *in toto* from Cromwell's church policy. It was Milton's fixed idea, almost his deepest idea, that there should be no such thing as an Established Church, or state-paid clergy, of any sort or denomination or mixture of denominations, in any nation, and that, as it had been the connexion between church and state, begun by Constantine, that had vitiated Christianity in the world, and kept it vitiated, so Christianity would never flourish as it ought till there had been universal disestablishment and disendowment of the clergy, and the propagation of the gospel were left to the zeal of voluntary pastors, self-supported, or supported modestly by their flocks. He had at one time looked to Cromwell as the likeliest man to carry this great revolution in England. But Cromwell, after much meditation on the subject in 1652 and 1653, had come to the opposite conclusion. The conservation of the Established Church of England, in the form of a broad union of all evangelical denominations of Christians, whether Presbyterians, or Independents, or Baptists, or moderate Old Anglicans, that would accept state-pay with state-control, had been the fundamental notion of his Protectorate, persevered in to the end. This must have been Milton's deepest disappointment with Cromwell's rule.

Cromwell's death on the 3rd of September 1658 left the Protectorship to his son Richard. Milton and Marvell continued in their posts, and a number of the Foreign Office letters of the new Protectorate were of Milton's composition. In October 1658 appeared a new edition of his *Defensio prima*, and, early in 1659, a new English pamphlet, entitled *Treatise of Civil Power in Ecclesiastical Causes showing that it is not lawful to compel in Matters of Religion*, in which he advocated the separation of Church and State. To Richard's Protectorate also belongs one of Milton's Latin "Familiar Epistles."

The last of his known official performances in his Latin secretaryship are two letters in the name of William Lenthall, as the speaker of the restored Rump, one to the king of Sweden and one to the king of Denmark, both dated the 15th of May 1659. Under the restored Rump, if ever, he seemed to have a chance for his notion of church-disestablishment; and accordingly, in August 1659, he put forth, with a prefatory address to that body, a pamphlet entitled *Considerations touching the likeliest means to remove Hirelings out of the Church.* The restored Rump had no time to attend to such matters. They were in struggle for their own existence with the army chiefs; and to prevent the restoration of the monarchy, to argue against it and fight against it to the last, was the work to which Milton set himself; the preservation of the republic in any form, and by any compromise of differences within itself, had become his one thought, and the study of practical means to this end his most anxious occupation. In a *Letter to a Friend concerning the Ruptures of the Commonwealth,* written in October 1659, he had propounded a scheme of a kind of dual government for reconciling the army chiefs with the Rump; through the following winter, marked only by two of his Latin "Familiar Epistles," his anxiety over the signs of the growing enthusiasm throughout the country for the recall of Charles II. had risen to a passionate vehemence which found vent in a pamphlet entitled *The Ready and Easy Way to Establish* *a Free Commonwealth, and the Excellence thereof compared with the Inconveniences and Dangers of readmitting Kingship to this Nation.* An abridgment of this pamphlet was addressed by him to General Monk in a letter entitled "The Present Means and Brief Delineation of a Free Commonwealth" (March 1660). Milton's proposal was that the central governing apparatus of the British Islands for the future should consist of one indissoluble grand council or parliament, which should include all the political chiefs, while there should be a large number of provincial councils or assemblies sitting in the great towns for the management of local and county affairs.

Not even when the king's cause was practically assured would Milton be silent. In *Brief Notes upon a late Sermon*, published in April 1660, in reply to a Royalist discourse by a Dr Matthew Griffith, he made another protest against the recall of the Stuarts, even hinting that it would be better that Monk should become king himself; and in the same month he sent forth a second edition of his *Ready and Easy Way*, more frantically earnest than even the first, and containing additional passages of the most violent denunciation of the royal family, and of prophecy of the degradation and disaster they would bring back with them. This was the dying effort. On the 25th of April the Convention Parliament met; on the 1st of May they resolved unanimously that the government by King, Lords and Commons should be restored; and on the 29th of May, Charles II. made his triumphal entry into London. The chief republicans had by that time scattered themselves, and Milton was hiding in an obscure part of the city.

How Milton escaped the scaffold at the Restoration is a mystery now, and was a mystery at the time. The Commons voted that he should be taken into custody by the serjeant-at-arms, for prosecution by the attorney-general on account of his *Eikonoklastes* and *Defensio prima*, and that all copies of those books should be called in and burnt by the hangman. There was a story that Milton had once protected Davenant and now owed his immunity to him; but it is more likely that he was protected by the influence of Marvell, by Arthur Annesley, afterwards earl of Anglesey, and by other friends who had influence at court. At all events, on the 29th of August 1660, when the Indemnity Bill did come out complete, with the king's assent, Milton did not appear as one of the exceptions on any ground or in any of the grades. From that moment, therefore, he could emerge from his hiding, and go about as a free man. Not that he was yet absolutely safe. There were several public burnings by the hangman at the same time of Milton's condemned pamphlets; and the appearance of the blind man himself in the streets, though he was legally free, would have caused him to be mobbed and assaulted. Though the special prosecution ordered against him by the Commons had been quashed by the subsequent Indemnity Bill, the serjeant-at-arms had taken him into custody. Entries in the Commons journals of the 17th and 19th of December show that Milton complained of the exorbitant fees charged by the serjeant-at-arms for his release, and that the matter was referred to a committee at the instance of Andrew Marvell.

Milton did not return to Petty France. For the first months after he was free he lived as closely as possible in a house near what is now Red Lion Square, Holborn. Thence he removed, apparently early in 1661, to a house in Jewin Street, in his old Aldersgate Street and Barbican neighbourhood. In Jewin Street Milton remained for two or three years, or from 1661 to 1664. This is the time of which he says:—

> " . . . though fallen on evil days,
> On evil days though fallen, and evil tongues,
> In darkness, and with dangers compassed round,
> And solitude."

The "evil days" were those of the Restoration in its first or Clarendonian stage, with its revenges and reactions, its return to high Episcopacy and suppression of every form of dissent and sectarianism, its new and shameless royal court, its open proclamation and practice of anti-Puritanism in morals and in literature no less than in politics. For the main part of this world of the Restoration Milton was now nothing more than an infamous outcast, the detestable blind republican and regicide who had, by too great clemency, been left unhanged. The friends that adhered to him still, and came to see him in Jewin Street, were few in number, and chiefly from the ranks of those nonconforming denominations, Independents, Baptists or Quakers, who were themselves under similar obloquy. Besides his two nephews, the faithful Andrew Marvell, Cyriack Skinner and some others of his former admirers, English or foreign, we hear chiefly of a Dr Nathan Paget, who was a physician in the Jewin Street neighbourhood, and of several young men who would drop in upon him by turns, partly to act as his amanuenses, and partly for the benefit of lessons from him— one of them a Quaker youth, named Thomas Ellwood. With all this genuine attachment to him of a select few, Milton could truly enough describe his condition after the Restoration as one of "solitude." Nor was this the worst. His three daughters, on whom he ought now to have been able principally to depend, were his most serious domestic trouble. The poor motherless girls, the eldest in her seventeenth year in 1662, the second in her fifteenth and the youngest in her eleventh, had grown up, in their father's blindness and too great self-absorption, ill-looked-after and but poorly educated; and the result now appeared. They "made nothing of neglecting him"; they rebelled against the drudgery of reading to him or otherwise attending on him; they "did combine together and counsel his maid-servant to cheat him in her marketings"; they actually "had made away some of his books, and would have sold the rest."

It was to remedy this state of things that Milton consented to a third marriage. The wife found for him was Elizabeth Minshull, of a good Cheshire family, and a relative of Dr Paget. They were married on the 24th of February 1662/3, the wife being then only in her twenty-fifth year, while Milton was in his fifty-fifth. She proved an excellent wife; and the Jewin Street household, though the daughters remained in it, must have been under better management from the time of her entry into it. Meanwhile, he had found some solace in renewed industry of various kinds among his books and tasks of scholarship, and more particularly he had been building up his *Paradise Lost.* He had begun the poem in earnest, we are told, in 1658 at his house in Petty France, not in the dramatic form contemplated eighteen years before, but deliberately in the epic form. He had made but little way when there came the interruption of the anarchy preceding the Restoration and of the Restoration itself; but the work had been resumed in Jewin Street and prosecuted there steadily, by dictations of twenty or thirty lines at a time to whatever friendly or hired amanuensis chanced to be at hand. Considerable progress had been made in this way before his third marriage; and after that the work proceeded apace, his nephew, Edward Phillips, who was then out in the world on his own account, looking in when he could to revise the growing manuscript.

It was not in the house in Jewin Street, however, that *Paradise Lost* was finished. Not very long after the third marriage, probably in 1664, he removed to another house, with a garden, in "Artillery Walk, leading to Bunhill Fields." Here *Paradise Lost* was certainly finished before July 1665—Aubrey says in 1663—for when Milton and his family, to avoid the Great Plague of London, went into temporary country-quarters in a cottage in Chalfont St Giles, Buckinghamshire,[1] the finished manuscript was taken with him, in probably more than one copy. This we learn from Thomas Ellwood, who had taken the cottage for him, and was allowed to take a copy of the manuscript way with him for perusal, during Milton's stay at Chalfont (*Life of Thomas Ellwood*, 1714). The delay in the publication of the poem may be explained partly by the fact that the official licenser hesitated before granting the necessary imprimatur to a book by a man of such notorious republican antecedents, and partly by the paralysis of all business in London by the Great Fire of September 1666. It was not till the 27th of April 1667 that Milton concluded an agreement, still preserved in the British

---

[1] Milton's cottage here is still standing, and is open to visitors.

Museum, with Samuel Simmons, printer, of Aldersgate Street, London, to dispose of the copyright for £5 down, the promise of another £5 after the sale of the first edition of 1300 copies, and the further promise of two additional sums of £5 each after the sale of two more editions of the same size respectively. It was as if an author now were to part with all his rights in a volume for £17, 10s. down, and a contingency of £52, 10s. more in three equal instalments. The poem was duly entered by Simmons as ready for publication in the Stationers' Registers on the 20th of the following August; and shortly after that date it was out in London as a neatly printed small quarto, with the title *Paradise Lost: A Poem written in Ten Books: By John Milton.* The reception accorded to *Paradise Lost* has been quoted as an example of the neglect of a great work, but the sale of an edition of 1300 copies in eighteen months proves that the poem found a wide circle of readers. "This man cuts us all out, and the ancients too" is the saying attributed to Dryden on the occasion; and it is the more remarkable because the one objection to the poem which at first, we are told, "stumbled many" must have "stumbled" Dryden most of all. Except in the drama, rhyme was then thought essential in anything professing to be a poem; blank verse was hardly regarded as verse at all; Dryden especially had been and was the champion of rhyme, contending for it even in the drama. That, notwithstanding this obvious blow struck by the poet at Dryden's pet literary theory, he should have welcomed the poem so enthusiastically and proclaimed its merits so emphatically, says much at once for his critical perception and for the generosity of his temper. According to Aubrey, Dryden requested Milton's leave to turn the poem into a rhymed drama, and was told he might "tag his verses if he pleased." The result is seen in Dryden's opera, *The State of Innocence and the Fall of Man* (1675). One consequence of Milton's renewed celebrity was that visitors of all ranks again sought him out for the honour of his society and conversation. His obscure house in Artillery Walk, Bunhill, we are told, became an attraction now, "much more than he did desire," for the learned notabilities of his time.

Accounts have come down to us of Milton's personal appearance and habits in his later life. They describe him as to be seen every other day led about in the streets in the vicinity of his Bunhill residence, a slender figure, of middle stature or a little less, generally dressed in a grey cloak or overcoat, and wearing sometimes a small silver-hilted sword, evidently in feeble health, but still looking younger than he was, with his lightish hair, and his fair, rather than aged or pale, complexion. He would sit in his garden at the door of his house, in warm weather, in the same kind of grey overcoat, "and so, as well as in his room, received the visits of people of distinguished parts, as well as quality." Within doors he was usually dressed in neat black. He was a very early riser, and very regular in the distribution of his day, spending the first part, to his midday dinner, always in his own room, amid his books, with an amanuensis to read for him and write to his dictation. Music was always a chief part of his afternoon and evening relaxation, whether when he was by himself or when friends were with him. His manner with friends and visitors was extremely courteous and affable, with just a shade of stateliness. In free conversation, either at the midday dinner, when a friend or two happened, by rare accident, to be present, or more habitually in the evening and at the light supper which concluded it, he was the life and soul of the company, from his "flow of subject" and his "unaffected cheerfulness and civility," though with a marked tendency to the satirical and sarcastic in his criticisms of men and things. This tendency to the sarcastic was connected by some of those who observed it with a peculiarity of his voice or pronunciation. "He pronounced the letter *r* very hard," Aubrey tells us, adding Dryden's note on the subject: "*litera canina*, the dog-letter, a certain sign of a satirical wit." He was extremely temperate in the use of wine or any strong liquors, at meals and at all other times; and when supper was over, about nine o'clock, "he smoked his pipe and drank a glass of water, and went to bed." He suffered much from gout, the effects of which had become apparent in a stiffening of his hands and finger-joints, and the recurring attacks of which in its acute form were very painful. His favourite poets among the Greeks were Homer and the Tragedians, especially Euripides; among the Latins, Virgil and Ovid; among the English, Spenser and Shakespeare. Among his English contemporaries, he thought most highly of Cowley. He had ceased to attend any church, belonged to no religious communion, and had no religious observances in his family. His reasons for this were a matter for curious surmise among his friends, because of the profoundly religious character of his own mind; but he does not seem ever to have furnished the explanation. The matter became of less interest perhaps after 1669, when his three daughters ceased to reside with him, having been sent out "to learn some curious and ingenious sorts of manufacture that are proper for women to learn, particularly embroideries in gold or silver." After that the household in Bunhill consisted only of Milton, his wife, a single maid-servant, and the "man" or amanuensis who came in for the day.

The remaining years of Milton's life, extending through that part of the reign of Charles II. which figures in English history under the name of the "Cabal Administration," were by no means unproductive. In 1669 he published, under the title of *Accedence commenced Grammar*, a small English compendium of Latin grammar that had been lying among his papers. In 1670 there appeared, with a prefixed portrait of him by Faithorne, done from the life, his *History of Britain . . . to the Norman Conquest*, being all that he had been able to accomplish of his intended complete history of England; and in the same year a Latin digest of Ramist logic, entitled *Artis logicae plenior institutio*, of no great value, and doubtless from an old manuscript of his earlier days. In 1671 there followed his *Paradise Regained* and *Samson Agonistes*, bound together in one small volume, and giving ample proof that his poetic genius had not exhausted itself in the preceding great epic. In 1673, at a moment when the growing political discontent with the government of Charles II. and the conduct of his court had burst forth in the special form of a "No-Popery" agitation and outcry, Milton ventured on the dangerous experiment of one more political pamphlet, in which, under the title "Of True Religion, Heresy, Schism, Toleration, and what best means may be used against the growth of Popery," he put forth, with a view to popular acceptance, as mild a version as possible of his former principles on the topics discussed. In the same year appeared the second edition of his *Poems . . . both English and Latin*, which included, with the exception of the Sonnets to Cromwell, Fairfax, Vane and the second address to Cyriack Skinner, all the minor poems.

Thus we reach the year 1674, the last of Milton's life. One incident of that year was the publication of the second edition of *Paradise Lost*, with the poem rearranged as now—into twelve books, instead of the original ten. Another was the publication of a small volume[1] containing his Latin *Epistolae familiares*, together with the *Prolusiones oratoriae* of his student-days at Cambridge—these last thrown in as a substitute for his Latin state-letters in his secretaryship for the Commonwealth and the Protectorate, the printing of which was stopped by order from the Foreign Office. A third publication of the same year, and probably the very last thing dictated by Milton, was a translation of a Latin document from Poland, relating to the recent election of the heroic John Sobieski to the throne of that kingdom, with the title *A Declaration or Letters Patents of the Election of this present King of Poland, John the Third.* It seems to have been out in London in August or September 1674. On Sunday the 8th of the following November Milton died, in his house in Bunhill, of "gout struck in," at the age of sixty-five years and eleven months. He was buried, the next Thursday, in the church of St Giles, Cripplegate, beside his father; a considerable concourse attending the funeral.

Family.

Before the Restoration, Milton—what with his inheritance from his father, what with the official income of his Latin secretaryship—must have been a man of very good means indeed. Since then, however, various heavy losses, and the cessation of all official income, had greatly reduced his estate, so that he left but £900 (worth about or over £2700 now) besides furniture and household goods. By a word-of-mouth will, made in presence of his brother Christopher, he had bequeathed the whole to his widow, on the ground that he had done enough already for his "undutiful" daughters, and that there remained for them his interest in their mother's marriage portion of £1000, which had never been paid, but which their relatives, the Powells of Forest Hill, were legally bound for, and were now in circumstances to make good. The daughters, with the Powells probably abetting them, went to law with the widow to upset the will; and the decision of the court was that they should receive £100 each. With the £600 thus left, the widow, after some further stay in London, retired to Nantwich in her native Cheshire. There, respected as a pious member of a local Baptist congregation, she lived till 1727, having survived her husband fifty-three years. By that time all the three daughters were also dead. The eldest, Ann Milton, who was somewhat deformed, had died not long after her father, having married "a master-builder," but left no issue; the second, Mary Milton, had died, unmarried, before 1694; and only the third, Deborah, survived as long as her step-mother. Having gone to Ireland, as companion to a lady, shortly before her father's death, she had married an Abraham Clarke, a silk-weaver in Dublin, with whom she returned to London about 1684, when they settled in the silk-weaving business in Spitalfields, rather sinking than rising in the world, though latterly some public attention was paid to Deborah, by Addison and others, on her father's account. One of her sons, Caleb Clarke, had gone out to Madras in 1703, and had died there as "parish-clerk of Fort George" in 1719, leaving children, of whom there are some faint traces to as late as 1727, the year of Deborah's death. Except for the possibility of further and untraced descent from this Indian grandson of Milton, the direct descent from him came to an end in his granddaughter, Elizabeth Clarke, another of Deborah's children. Having married a Thomas Foster, a Spitalfields weaver, but afterwards set up a small chandler's shop, first in Holloway and then in Shoreditch, she died at Islington in 1754, not long after she and her husband had received the proceeds of a performance of *Comus* got up by Dr Johnson for her benefit. All her children had predeceased her, leaving no issue. Milton's brother Christopher, who had always been on the opposite side in politics, rose to the questionable honour of a judgeship and knighthood in the latter part of the reign of James II. He had then become a Roman Catholic—which religion he professed till his death in retirement at Ipswich in 1692. Descendants from him are traceable a good way into the 18th century. Milton's two nephews and pupils, Edward and John Phillips, both of them known as busy and clever hack-authors before their uncle's death, continued the career of hack-authorship, most industriously and variously, though not very prosperously, through the rest of their lives: Edward in a more reputable manner than John, and with more of enduring allegiance to the memory of his uncle. Edward died about 1695; John was alive till 1706. Their half-sister, Ann Agar, the only daughter of Milton's sister by her second husband, had married, in 1673, a David Moore, of Sayes House, Chertsey; and the most flourishing of all the lines of descent from the poet's father was in this Agar-Moore branch of the Miltons.

[1] *Joannis Miltonii Angli epistolarum familiarum liber unus; quibus accesserunt ejusdem (jam olim in collegio adolescentis) prolusiones quaedam oratoriae* (1674; translation by J. Hall, 1829).

Posthumous Publications.

Of masses of manuscript that had been left by Milton, some portions saw the light posthumously. Prevented, in the last year of his life from publishing his Latin *State Letters* in the same volume with his Latin *Familiar Episiles*, he had committed the charge of the *State Letters*, prepared for the press, together with the completed manuscript of his Latin *Treatise of Christian Doctrines*, to a young Cambridge scholar, Daniel Skinner, who had been among the last of his amanuenses, and had, in fact, been employed by him especially in copying out and arranging those two important MSS. Negotiations were on foot, after Milton's death, between this Daniel Skinner and the Amsterdam printer, Daniel Elzevir, for the publication of both MSS., when the English government interfered, and the MSS. were sent back by Elzevir, and thrown aside, as dangerous rubbish, in a cupboard in the State Paper Office. Meanwhile, in 1676, a London bookseller, named Pitt, who had somehow got into his possession a less perfect, but still tolerably complete, copy of the *State Letters*, had brought out a surreptitious edition of them, under the title *Literae pseudo-senatus anglicani, Cromwellii . . . nomine et jussu conscriptae a Joanne Miltono*. No other posthumous publications of Milton's appeared till 1681, when another bookseller put forth a slight tract entitled *Mr John Milton's Character of the Long Parliament and Assembly of Divines*, in 1641, consisting of a page or two, of rather dubious authenticity, said to have been withheld from his *History of Britain* in the edition of 1670. In 1682 appeared *A Brief History of Moscovia, and of other less-known Countries lying Eastward of Russia as far as Cathay* . . . undoubtedly Milton's, and a specimen of those prose compilations with which he sometimes occupied his leisure. Of the fate of his collections for a new Latin *Dictionary*, which had swelled to three folio volumes of MS., all that is known is that, after having been used by Edward Phillips for his *Enchiridion* and *Speculum*, they came into the hands of a committee of Cambridge scholars, and were used for that Latin dictionary of 1693, called *The Cambridge Dictionary*, on which Ainsworth's *Dictionary* was based. In 1698 there was published in three folio volumes, under the editorship of John Toland, the first collective edition of Milton's prose works, professing to have been printed at Amsterdam, though really printed in London. A very interesting folio volume, published in 1743 by "John Nickolls, junior," under the title of *Original Letters and Papers of State addressed to Oliver Cromwell*, consists of a number of intimate Cromwellian documents that had somehow come into Milton's possession immediately after Cromwell's death, and were left by him confidentially to the Quaker Ellwood. Finally, a chance search in the London State Paper Office in 1823 having discovered the long-lost parcel containing the MSS. of Milton's Latin *State Letters* and his Latin *Treatise of Christian Doctrine*, as these had been sent back from Amsterdam a hundred and fifty years before, the *Treatise on Christian Doctrine* was, by the command of George IV., edited and published in 1825 by the Rev. C. R. Sumner, keeper of the Royal Library, and afterwards bishop of Winchester, under the title of *Joannis Miltoni Angli de doctrina christiana libri duo posthumi*. An English translation, by the editor, was published in the same year. Those state papers of Milton which had not been already printed were edited by W. D. Hamilton for the Camden Society, in 1859.

Milton's literary life divides into three almost mechanically distinct periods: (1) the time of his youth and minor poems, (2) his middle twenty years of prose polemics, and (3) the time of his later Muse and greater poems.

Characteristics.

Had Milton died in 1640, when he was in his thirty-second year, and had his literary remains been then collected, he would have been remembered as one of the best Latinists of his generation and one of the most exquisite of minor English poets. In the latter character, more particularly, he would have taken his place as one of that interesting group or series of English poets, coming in the next forty years after Spenser, who, because they all acknowledged a filial relationship to Spenser, may be called collectively the Spenserians. In this group or series, counting in it such other true poets of the reigns of James I. and Charles I. as Phineas and Giles Fletcher, William Browne and Drummond of Hawthornden, Milton would have been entitled, by the small collection of pieces he had left, and which would have included his *Ode on the Nativity*, his *L'Allegro* and *Il Penseroso*, his *Comus* and his *Lycidas*, to recognition as indubitably the very highest and finest. There was in him that peculiar Spenserian something which might be regarded as the poetic faculty in its essence, with a closeness and perfection of verbal finish not to be found in the other Spenserians, or even in the master himself. Few as the pieces were, and owning discipleship to Spenser as the author did, he was a Spenserian with a difference belonging to his own constitution—which prophesied, and indeed already exhibited, the passage of English poetry out of the Spenserian into a kind that might be called the Miltonic. This Miltonic something, distinguishing the new poet from other Spenserians, was more than mere perfection of literary finish. It consisted in an avowed consciousness already of the *os magna soniturum*, "the mouth formed for great utterances," that consciousness resting on a peculiar substratum of personal character that had occasioned a new theory of literature. "He who would not be frustrate of his hope to write well hereafter on laudable things ought himself to be a true poem" was Milton's own memorable expression afterwards of the principle that had taken possession of him from his earliest days; and this principle of moral manliness as the true foundation of high literary effort, of the inextricable identity of all literary productions in kind, and their coequality in worth, with the personality in which they have their origin, might have been detected, in more or less definite shape, in all or most of the minor poems. It is a specific form of that general Platonic doctrine of the invincibility of virtue which runs through his *Comus*.

That a youth and early manhood of such poetical promise should have been succeeded by twenty years of all but incessant prose polemics has been a matter of regret with many. But this is to ignore his political and social side. If Burke, whose whole public career consisted in a succession of speeches and pamphlets, is looked back upon as one of the greatest men of his century on their account, why should there be regret over the fact that Milton, after having been the author of *Comus* and *Lycidas*, became for a time the prose orator of *his* earlier and more tumultuous generation? Milton was not only the greatest pamphleteer of his generation—head and shoulders above the rest—but there is no life of that time, not even Cromwell's, in which the history of the great Revolution in its successive phases, so far as the deep underlying ideas and speculations were concerned, may be more intimately and instructively studied than in Milton's. Then, on merely literary grounds, what an interest in those prose remains! Not only of his *Areopagitica*, admired now so unreservedly because its main doctrine has become axiomatic, but of most of his other pamphlets, even those the doctrine of which is least popular, it may be said confidently that they answer to his own definition of "a good book," by containing somehow "the precious life-blood of a master-spirit." From the entire series there might be a collection of specimens, unequalled anywhere else, of the capabilities of that older, grander and more elaborate English prose of which the Elizabethans and their immediate successors were not ashamed. Nor will readers of Milton's pamphlets continue to accept the hackneyed observation that his genius was destitute of humour. Though his prevailing mood was the severely earnest, there are pages in his prose writings, both English and Latin, of the most laughable irony, reaching sometimes to outrageous farce, and some of them as worthy of the name of humour as anything in Swift. Here, however, we touch on what is the worst feature in some of the prose pamphlets—their measureless ferocity, their boundless licence in personal scurrility.

While it is wrong to regard Milton's middle twenty years of prose polemics as a degradation of his genius, and while the fairer contention might be that the youthful poet of *Comus* and *Lycidas* actually promoted himself, and became a more powerful agency in the world and a more interesting object in it for ever, by consenting to lay aside his "singing robes" and spend a portion of his life in great prose oratory, who does not exult in the fact that such a life was rounded off so miraculously at the close by a final stage of compulsory calm, when the "singing robes" could be resumed, and *Paradise Lost*, *Paradise Regained* and *Samson Agonistes* could issue in succession from the blind man's chamber? Of these three poems, and what they reveal of Milton, no need here to speak at length. *Paradise Lost* is one of the few monumental works of the world, with nothing in modern epic literature comparable to it except the great poem of Dante. This is best perceived by those who penetrate beneath the beauties of the merely terrestrial portion of the story, and who recognize the coherence and the splendour of that vast symbolic phantasmagory by which, through the wars in heaven and the subsequent revenge of the expelled archangel, it paints forth the connexion of the whole visible universe of human cognisance and history with the grander, pre-existing and still environing world of the eternal and inconceivable. To this great epic *Paradise Regained* is a sequel, and it ought to be read as such. The legend that Milton preferred the shorter epic to the larger is quite incorrect. All that is authentic on the subject is the statement by Edward Phillips that, when it was reported to his uncle that the shorter epic was "generally censured to be much inferior to the other," he "could not hear with patience any such thing." The best critical judgment now confirms Milton's own, and pronounces *Paradise Regained* to be not only, within the possibilities of its briefer theme, a worthy sequel to *Paradise Lost*, but also one of the most artistically perfect poems in any language. Finally, the poem in which Milton bade farewell to the Muse, and in which he reverted to the dramatic form, proves that to the very end his right hand had lost none of its power or cunning. *Samson Agonistes* is the most powerful drama in the English language after the severe Greek model, and it has the additional interest of being so contrived that, without any deviation from the strictly objective incidents of the Biblical story which it enshrines, it is yet the poet's own epitaph and his condensed autobiography.

Much light is thrown upon Milton's mind in his later life, and even upon the poems of that period, by his posthumous Latin *Treatise of Christian Doctrine*. It differs from all his other prose writings of any importance in being cool, abstract and didactic. Professing to be a system of divinity derived directly from the Bible, it is really an exposition of Milton's metaphysics and of his reasoned opinions on all questions of philosophy, ethics and politics. The general effect is to show that, though he is rightly regarded as the very genius of English Puritanism, its representative poet and idealist, yet he was not a Puritan of what may be called the first wave, or that wave of Calvinistic orthodoxy which broke in upon the absolutism of Charles and Laud, and set the English Revolution agoing. He belonged distinctly to that larger and more persistent wave of Puritanism which, passing on through Independency, and an endless variety of sects, many of them rationalistic and freethinking in the extreme, developed into what has ever since been known as English Liberalism. The treatise makes clear that, while Milton was a most fervid theist and a genuine Christian, believing in the Bible, and valuing the Bible over all the other books in the world, he was at the same time one of the most intrepid of English thinkers and theologians. (D. MA.; X.)

Portraits.

Considerable interest attaches among collectors to the variety of prints representing portraits of Milton. So far as the original contemporary portraits are concerned, which have inspired the large number of engravings, the following may be mentioned: (1) The existing Janssen painting, 1618 ("*aetatis suae* 10"), which belonged to Mrs Milton. (2) An unknown painting of 1623 (? 1620), from which was taken an engraving in the *Gentleman's Magazine* for September 1787 ("*aet. suae* 12"). (3) The "Onslow" painting of Milton when a Cambridge scholar (lost), which belonged to Mrs Milton and in 1794 was in Lord Onslow's possession; a copy by Van der Gucht was made for Lord Harcourt and is still at Nuneham. (4) William Marshal's engraved frontispiece to Moseley's edition of the poems (1645). (5) William Faithorne's engraving of Milton from life, at the age of sixty-two, in Milton's *History of Britain* (1670). (6) Faithorne's original drawing for the above, belonging in 1909 to Sir R. H. Hobart. (7) The Bayfordbury (or Tonson) drawing (probably by Faithorne, or (?) by White or Richardson) at Bayfordbury Park near Hertford. (8) A drawing by George Vertue in Dr Williamson's collection. (9) A clay bust (? by Pierce or Simon) at Christ's College. (10) A miniature by Cooper (1653), which is, however, considered by Dr G. C. Williamson not to be of Milton at all. (11) A painting by Pieter Van der Plas (d. 1704) in the National Portrait Gallery. (12) An oil painting at Christ's College. (13) The "Woodcock" miniature of Milton when about forty-eight. In Poets' Corner, Westminster Abbey, a bust by Rysbrack was put up in 1737. A monument in St Giles, Cripplegate, by John Bacon, R.A., was erected by Samuel Whitbread in 1793; and a modern statue by Horace Montford also stands there. A memorial window in St Margaret's, Westminster, with an inscription by J. G. Whittier, was presented by G. W. Childs, of Philadelphia.

BIBLIOGRAPHY.—MSS. of the poems of Milton's earlier period in his own handwriting are preserved in the library of Trinity College, Cambridge. These are not enumerated among the gifts made by Sir Henry Newton Puckering in 1691, but presumably belonged to him, and came to the library at his death in 1700, as they were found by Charles Mason, a fellow of the college, among papers and books which had been his. They were bound in a folio volume by the care of Thomas Clarke, afterwards Master of the Rolls, in 1736. Besides the poems, with many interlineations and corrections, the MS. contains suggestions, and in some cases fully developed plans, for works generally dramatic in form. This manuscript volume, invaluable as an index to Milton's methods of work, was reproduced in facsimile (Cambridge, 1899) by W. Aldis Wright.

The first complete edition of *The Poetical Works of Mr John Milton* . . . was printed by Jacob Tonson in 1695. In 1732 Richard Bentley put forward a curious edition of *Paradise Lost* in which long passages were rejected and placed in the margin on the ground that they were interpolations made possible by Milton's blindness. The Latin and Italian poems, with a translation by William Cowper, were printed by W. Hayley in 1808. The most important of the numerous later editions of Milton's poetical works are by H. J. Todd (6 vols., 1801); J. Mitford ("Aldine edition," 3 vols., 1832); T. Keightley (2 vols., 1859), whose notes are most original and interesting; D. Masson ("Library" or "Cambridge" edition, 3 vols., 1874; of which a new edition appeared in 1890, with memoir, introduction, notes and an essay on Milton's English and versification); John Bradshaw (new "Aldine edition," 2 vols., 1892); also a careful reprint retaining the peculiarities of the earlier printed copies, by H. C. Beeching ("Oxford edition," 1904); and another, with variant readings, by W. Aldis Wright (Cambridge University Press, 1903). The prose works were first partially collected in 1697. They were edited by J. Toland (3 vols., 1698), by C. Symmons (7 vols., 1806), by Pickering (8 vols., 1851) with the poetical works, and by J. A. St John for Bohn's "Libraries" (5 vols., 1848–1853). There are numerous annotated editions of separate works.

The earliest life of Milton is contained in Wood MS. D. 4 in the Bodleian Library, Oxford, and was printed in the *Eng. Hist. Review* for January 1902, also by E. S. Parsons in *Colorado College Studies*, No. X (1903). The author, who sympathized with the poet's political views, is unknown, but the name of Milton's friend, Dr Nathan Paget, is suggested. His account formed the basis of the life given by Anthony à Wood in *Fasti oxonienses* (1691). Wood was also indebted to John Aubrey, whose *Brief Lives* were not printed until later. The life by his nephew Edward Phillips was prefixed to the *Letters of State* printed in 1694, and reprinted by William Godwin in his *Lives of E. and J. Phillips* (1815). Samuel Johnson's famous *Life of Milton* (1779), which contains some valuable criticism, is written from a somewhat unfriendly standpoint. The records of Milton's official life, available in the State Papers, were first made use of by H. J. Todd in a third edition (1829) of his *Milton*. All the available information was gathered in Professor Masson's *Life of John Milton; narrated in Connexion with the Political, Ecclesiastical and Literary History of his Time* (6 vols., 1859–1880, with index, 1894; new ed. of vol. i., 1881) which contains ample reference to original authorities. Shorter works are *Milton und seine Zeit* (2 pts., 1877, 1879), by Alfred Stern; *Milton* (1879), by Mark Pattison in the "English Men of Letters" series, and *Life of John Milton* (1890) by Dr Richard Garnett in the "Great Writers" series, with a bibliography by J. P. Anderson.

The sources of *Paradise Lost* have given rise to much discussion. It has been supposed to owe something to *Adamo*, a comedy by Giovanni Battista Andreini (1578–1652), to the *Paraphrase* associated with the name of Caedmon which was printed at Amsterdam in 1655 by Francis Junius, and to the *Lucifer* and other plays of Joost van den Vondel. Parallelisms between Vondel and Milton were pointed out by Mr Edmund Gosse in *Literatures of Northern Europe* (1879), and the comparison was carried further in Mr G. Edmundson's *Milton and Vondel; A Curiosity of Literature* (1885), a book which aroused much discussion. A valuable contribution to Miltonic criticism was made in 1893 by Mr Robert Bridges in an essay on *Milton's Prosody*. This was reprinted in 1901, with some additional matter and an essay on "Classical Metres in English Verse" by W. J. Stone. Amongst other critical essays should be mentioned essays by Macaulay (*Edinburgh Review*, 1825); Walter Bagehot (*Literary Studies*, vol. i., 1879); S. T. Coleridge (*Seven Lectures on Shakespeare and Milton* 1856); Edward Dowden (*Transcripts and Studies*, 1888); Edmond Scherer (*Études sur la littérature contemporaine*, vol. vi., 1882); Augustine Birrell (*Obiter dicta*, second series 1887); Walter Raleigh (*Milton*, 1900); E. Allodoli, *Giovanni Milton e l'Italia* (Prato, 1907).

Concordances of Milton's *Poetical Works* were compiled by G. L. Prendergast (Madras, 1856–1857); by C. J. Cleveland (1867), based on a verbal index used in an American edition 1853, of the *Poetical Works*; by John Bradshaw (1894), by L. E. Lockwood, *Lexicon to the English Poetical Works of John Milton* (New York, 1907).

The tercentenary of Milton's birth was celebrated in 1908 in Cambridge, London and elsewhere. An exhibition of the portraits of Milton, authentic and supposed, with a great collection of valuable editions of the poet's works, was held in June and July at Christ's College, Cambridge. The catalogue of this exhibition, drawn up by Dr G. C. Williamson, forms a valuable bibliography and iconography of the poet. A collection of Milton autographs, early editions and portraits was also held in December at the British Museum, and the anniversary itself was celebrated by a special meeting of the British Academy, at which papers by Professors W. J. Courthope, Edward Dowden and others were read. There was a religious service at St Mary-le-Bow, Cheapside, and a banquet at the Mansion House.

MILTON, a township of N.E. Norfolk county, Massachusetts, U.S.A., about 7 m. S. of Boston, the Neponset river forming a large part of its N. and N.W. boundary. Pop. (1890), 4278; (1900), 6578 (1840 being foreign-born); (1905, state census), 7054; (1910) 7924. It is served by the New York, New Haven & Hartford railway, and is primarily a residential suburb of Boston, with which it is connected by electric lines. The township covers an area of about 13 sq. m., and includes the villages of Milton, East Milton and Mattapan. The country is rolling and hilly, the Blue Hills (with the exception of a part included in Braintree in 1712 and now in Quincy) lying in Milton. On Great Blue Hill, the highest (635 ft. above tide-level), great fires were kindled at the news of the repeal of the Stamp Act, of the adoption of the Declaration of Independence, and of the surrenders of Burgoyne and Cornwallis; beacon fires were burned during the American War of Independence; an "observatory" for tourists was built at an early date; and in 1885 the Blue Hill Observatory for meteorological investigation was established by Abbott Lawrence Rotch (b. 1861), who made important investigations concerning clouds, and attracted attention by his use of kites for obtaining meteorological data. Milton Academy (a non-sectarian school) was founded in 1798, opened in 1805, and suspended in 1867; a new academy was opened in 1885. There is a public library, which was opened in 1871, and in 1909 had more than 20,000 volumes. Cunningham Park is under the control of the trustees of a fund left for the benefit of the township, and contains a gymnasium, skating-pond, tennis courts, &c., open to townspeople only. Hutchinson Field, another public park, is a part of the estate of the last royal governor, Thomas Hutchinson; Governor Jonathan Belcher also lived in Milton for a time. There are two granite quarries in the township immediately north-west of the Blue Hills; the granite is of the "dark Quincy" variety—dark bluish grey in colour—and is used chiefly for monuments. Milton, originally a part of Dorchester, was first settled in 1640, and was called Uncataquissett. The township was separated from Dorchester and incorporated in 1662. It owes its name either to its early paper and grist mills (Milton being abbreviated from Milltown) or to Milton Abbey, Dorset, whence members of the Tucker family came, it is supposed, to Milton about 1662. In 1712 the Blue Hill lands were divided between Milton and Braintree, and in 1868 part of Milton was included in the new township of Hyde Park. In Milton, on the 9th of September 1774, at the house of Daniel Vose, a meeting, adjourned from Dedham, passed the bold "Suffolk Resolves" (Milton then being included in Suffolk county), which declared that a sovereign who breaks his compact with his subjects forfeits their allegiance, that parliament's repressive measures were unconstitutional, that tax-collectors should not pay over money to the royal treasury, that the towns should choose militia officers from the patriot party, that they would obey the Continental Congress and that they favoured a Provincial Congress, and that they would seize crown officers as hostages for any political prisoners arrested by the governor; and recommended that all persons in the colony should abstain from lawlessness.

See A. K. Teele, *History of Milton, Mass., 1640 to 1887* (Milton, 1887).

MILTON, a borough of Northumberland county, Pennsylvania, U.S.A., on the Susquehanna river at the mouth of Limestone Run, about 66 m. N. of Harrisburg. Pop. (1890), 5317; (1900), 6175 (166 foreign-born); (1910), 7460. It is served by the Pennsylvania, and the Philadelphia & Reading railways, and is connected with Lewisburg and Watsontown by an electric line. Milton has an attractive public park, is in an agricultural region, and has various manufactures. It was founded in 1792, and incorporated as a borough in 1817. In 1880 it was in great part destroyed by fire.

MILWAUKEE, a city and the county-seat of Milwaukee county, Wisconsin, U.S.A., the largest city of the state, at the mouth of the Milwaukee river on the W. shore of Lake Michigan, about 85 m. N. of Chicago. Pop. (1900), 285,315; (1910), 373,857. The Milwaukee river entering the city from the north is joined about ½ m. from its mouth by the Menominee flowing from the west and a short distance from the lake by the Kinnikinnic flowing from the south. These rivers are navigable for lake traffic into the heart of the city. Milwaukee Bay, into which their combined waters empty, is an inlet of Lake Michigan, about 6 m. across. By the construction of extensive piers and breakwaters a fine harbour of refuge has been created; and its inner harbour is deep enough for the largest lake-steamers.

From the shore of the lake the land rises, rather abruptly in most places, to a height of from 75 to 100 ft. From a broad plateau overlooking the lake the land slopes gradually westward to the river, again rising on the north, west and south to a height of 125 ft. or more. The rivers separate the city into three distinctly marked divisions of varying character known as the east, west and south sides. The manufactories are largely on the "flats" along the rivers and on the south side. The extensive use as building material of cream-coloured brick made in the vicinity gives the city its nickname, "the Cream City."

The city has many beautiful parks and squares, the most picturesque of which is Juneau Park, along the lake bluff. It contains statues of Leif Ericsson and Solomon Juneau. Other parks are Lake Park, also on the lake shore, at North Point, where stands the waterworks pumping station with its tall tower; Riverside and Kilbourn Parks, east and west respectively of the upper Milwaukee river, in the northern part of the city, Washington Park on the west side, containing a menagerie and a herd of deer; Sherman Park on the west side, and Kosciusko, Humboldt and Mitchell Parks on the south side. McKinley Park on the lake shore south of the city, and Whitefish Bay 6 m. north of the city, are popular bathing resorts. In addition to the statues in Juneau Park there is a statue of Kosciusko in the park of that name; one of Washington and a soldiers' monument on Grand Avenue; a statue of Henry Bergh in front of the city hall; one of Robert Burns in the First Ward Park, and, in Washington Park, a replica of Ernst Rietschel's Schiller-Goethe monument in Jena, given to the city in 1908 by the Germans of Milwaukee. Of the several cemeteries, that of Forest Home, south-west of the city, is the largest and most beautiful. The city is well sewered, and has an excellent water-supply system owned by the municipality and representing an investment of more than $5,000,000. The water is obtained from Lake Michigan through an intake far out in the lake. Through a tunnel ½ m. long, constructed in 1888, water is pumped by means of one of the largest single pumps in the world from the lake into the upper Milwaukee river, which is thus completely flushed by fresh water every twenty-four hours.

Milwaukee is one of the most healthful of the larger cities of the United States. Its average annual death-rate for 1900–1904 was 13·6. The proximity of Lake Michigan cools the atmosphere in summer and tempers the cold in winter. As a result, the extremes of heat and cold are not as great as those in most inland cities. The mean monthly temperatures vary between 20° in January and 70° in July, with extremes of 100° and −25°. The mean annual precipitation is 31·4 in.

Suburbs.—Milwaukee proper occupies 22½ sq. m., a small area as compared with other cities near it in population—Detroit (36 sq. m.) and Washington, D.C. (69¼ sq. m.). As a result, the population has overflowed into several populous suburbs industrially a part of a "greater" Milwaukee. Of these by far the most important are the township of Wauwatosa (pop., 1905, 11,132; 1910, 11,536), and the city of the same name, separated from the township in 1897 and having in 1910 a population of 3346; the city and township are on the Menominee river, immediately adjoining the city on the west. The first settlement was made here in 1835. Wauwatosa has important manufactures, including machinery. brick, lime, beer, chemicals and wooden-ware, and extensive market gardens and nurseries and valuable stone quarries. It has a Carnegie library, and is the seat of an Evangelical Lutheran theological seminary (1865), of Lutheran homes for the aged and orphan, of the Milwaukee county hospital for the insane, of the Milwaukee sanatorium for nervous diseases, and of the north-western branch of the national soldiers' home, which has grounds covering 385 acres and with main building and barracks affording quarters for over 2000 disabled veterans, and has a hospital, a theatre, and a library of 15,000 volumes. Within the limits of Wauwatosa also are the State Fair grounds. Other suburbs are West Allis pop., 1905, 2306; U. S. census 1910, 6645), an incorporated rapidly growing manufacturing city on the west; Cudahy (pop., 1910, 3691), a manufacturing village south of Milwaukee, largely devoted to meat packing; South Milwaukee (pop. 1910, 6092), an incorporated city with several large manufactories, and North Milwaukee (pop., 1910, 1860), a village immediately adjoining the city on the north.

Public Buildings, Institutions, &c.—The principal public building in the city is the Federal building (1895–1898), the post office, customhouse and local headquarters for the United States courts. The public library and museum, on the north side of Grand Avenue, in addition to an excellent collection of natural history, palaeontology, &c., contained in 1909 a library of about 190,000 volumes. The city hall on the east side is surmounted by a tall clock-tower containing one of the largest bells in the world. The Layton Art Gallery contains one of the best collections of paintings west of the Alleghanies. The chamber of commerce, and the Pabst, Mitchell, North-Western Life Insurance, Germania Sentinel and Wells buildings, are among the principal business structures. In Milwaukee are St John's Roman Catholic Cathedral and All Saints Protestant Episcopal Cathedral—the city is the see of a Roman Catholic archbishopric (established in 1892) and of a Protestant Episcopal bishopric. Among other church structures are Plymouth Congregational, Westminster Presbyterian, Church of Gesu (Roman Catholic) and Trinity Lutheran. The hotels include the Pfister on the east side and the Plankinton, the Republican and the Schlitz on the west side. Among the theatres are the Davidson, Majestic, Schubert, Bijou, Alhambra and the Pabst German. During the summer there are open-air theatres in several private parks or "gardens." The social clubs include the Milwaukee, Deutscher-Concordia, University and Marquette clubs. The predominance of Germanic influence in the city is evidenced by at least 75 musical clubs and numerous *Turnverein* societies. There are 12 hospitals (3 of them city institutions), 6 orphan asylums, 4 homes for the aged, a foundlings' home and a state industrial school for girls.

The educational institutions are numerous. Marquette University was established in 1906 by a union of Marquette College (1881), a Roman Catholic school of high rank, and existing schools of medicine, pharmacy, dentistry and law; in 1908 it added a department of engineering, and in that year it had 81 instructors and 630 students. Milwaukee-Downer College (for girls), in the north-east part of the city was established in 1895 by a consolidation of Milwaukee College for girls, and Downer College, formerly at Fox Lake. Other institutions are Concordia College (1881, Lutheran), a state normal school (1880), the Wisconsin College of physicians and surgeons (1893), the national German-American teachers' seminary (normal), Milwaukee academy (1864), Milwaukee University school, Milwaukee school of engineering (1904), Milwaukee Turnverein school of physical culture, one of the largest schools of the sort in the United States, St John's Catholic institute, Our Lady of Mercy academy (Roman Catholic), Wisconsin academy of music, the Wisconsin school of art (art students' league), a Catholic normal school, St Rose's manual training school, the industrial chemical institute (the only technical school for brewers in the United States) and several business and commercial schools. At St Francis, adjoining the city on the south, is the seminary of St Francis of Sales (Roman Catholic), and St Joseph's institute for deaf mutes (Roman Catholic). The Milwaukee public school system comprises four high schools, a high school of trades, and in addition to the ordinary grades, a kindergarten department and day schools for the blind and deaf.

Transportation.—Milwaukee is favourably situated commercially, with excellent facilities for shipping both by lake and rail afforded by four trunk lines and a dozen lines of lake steamboats. It is served by the Chicago & North-Western, the Chicago, Milwaukee & St Paul, the Minneapolis, St Paul & Sault Ste Marie, the Grand Trunk, and the Père Marquette railways. The last-named connects with the main line at Ludington, Michigan, by means of a railway ferry across Lake Michigan; the Grand Trunk has a railway ferry from Milwaukee to Grand Haven. The city's extensive street railway system connects with interurban electric lines leading to Waukesha, Oconomowoc and Watertown on the west, Sheboygan and Fond du Lac on the north, and Chicago and intermediate points along the lake shore on the south.

Trade and Commerce.—Commercially Milwaukee is one of the most important of the inland cities of the United States, although its trade it largely domestic. It is a distributing point for a considerable part of Wisconsin, and several states farther west, its wholesale business aggregating about $350,000,000 annually. The country produce sold in Milwaukee averages about $75,000,000 a year in value. The chief commodities of trade are coal, grain, lumber, flour and various products of the city's own manufactories. Milwaukee is an important grain shipping port—in 1908 it shipped 28,618,519 bushels of grain and 3,752,033 barrels of flour, and its 25 elevators have a capacity of over 12,500,000 bushels. It is one of the largest distributing centres in the country for coal, which is received by lake, and stored in enormous coal docks for transshipment by rail throughout the west and north-west. The city is a port of entry, and in 1908 its imports were valued at $3,080,437, and its exports at only $75,525.

Manufactures.—In 1905 the total value of Milwaukee's factory products was $138,881,545, 25·3% more than in 1900. In the manufacture of malt liquors and malt Milwaukee stands first among the cities of the United States and of the world. The total value of these products for 1905 was $29,909,248, of which $22,134,580 was the value of malt liquors and $3,774,668 was the value of malt. In 1905 Milwaukee manufactured 77·1% of the malt liquors manufactured in the state and 7·4% of the entire product of the United States. Other products exceeding $1,000,000 in value were: leather ($14,074,397), Milwaukee being second in the manufacture of leather among the cities of the United States: foundry and machine shop products ($10,232,723); iron and steel ($7,010,793); flour and grist-mill products ($6,320,428); slaughtering and meat-packing products ($5,958,515); men's clothing ($4,759,548); boots and shoes ($2,929,405); electrical machinery, apparatus and supplies ($2,257,229); chewing and smoking tobacco ($1,966,930) and cigars and cigarettes ($1,540,019); furniture ($1,767,290); trunks and valises ($1,623,310); hosiery and knit goods ($1,535,176); confectionery ($1,379,668); stoves and furnaces ($1,288,931); leather gloves and mittens ($1,207,633); structural iron work ($1,037,217); wooden packing boxes ($1,024,750); and paints ($1,015,774). Among Milwaukee's largest industrial establishments are: the Pabst and the Schlitz breweries, on the west side of the city, the machine shops (35 acres) of the Allis-Chalmers Company at West Allis, employing about 5000 men and making engines of all kinds; and the plant of the Illinois Steel Company, at Bay View on the south side, which covers 154 acres. The flour mills of Milwaukee have a capacity of about 12,000 barrels a day. Two of the city's tanneries are among the largest in America. In the Menominee river valley the peculiar cream-coloured Milwaukee bricks are made. North of the city on the Milwaukee river are extensive cement works.

Newspapers.—The first newspaper in Milwaukee, the *Advertiser*, began publication in 1836. The first German newspaper was established in 1844. In 1909 there were eleven daily newspapers, as follows: *Evening Wisconsin* (1847; Republican), *Free Press* (1901; Independent Republican), *Journal* (1882; Independent Democrat), *News* (1886; Independent), and *Sentinel* (1837; Republican), the oldest paper in continuous publication, *Daily Commercial Letter* (Commercial), *Reporter* (legal and commercial), *Dziennik Milwaucki* (Polish), *Kuryer Polski* (1888; Republican; Polish), *Germania Abendpost* (1872; Independent; German); and *Der Herold* (1854; Independent; German). Of more than a hundred other publications thirty-two, 10 monthly or quarterly and 22 weekly, were published in German. There are 5 Polish weekly publications, 3 Bohemian, 1 Italian and one periodical for the blind.

Population.—The population of Milwaukee in 1840 was only 1712. During the following decade there was a steady flow of immigrants from the eastern states and from Europe, with the result that in 1850, two years after the admission of Wisconsin to the Union, the population was 20,061. The population at the succeeding decennial censuses was as follows: (1860), 45,246; (1870), 71,440; (1880), 115,587; (1890), 204,468; (1900), 285,315. In 1905, according to the state census, the population was 312,948. The fact that out of a population of 285,315 in 1900, 88,991 were foreign-born, and 235,889 were of foreign parentage, that 53,854 were born in Germany, that 124,211 had both parents born in Germany, and that 26,834 additional had one or the other parent born in Germany, stamps the character of Milwaukee's population. The negro population in 1900 was only 862. The proportion of illiterates is small. Of the male population, aged 10 years or more, only 3206 (2968 foreign-born whites; 194 native-born whites) were illiterate in 1900.

Government.—Milwaukee is governed under a city charter of 1874, providing the form of city government most common in America, a mayor (elected biennially) and a single board of aldermen. There are the usual administrative boards whose members are appointed by the mayor, some of them with the approval of the board of aldermen, though the board of school directors is elected by direct popular vote. Two boards of civil service commissioners, one for fire and police departments and one for all other departments, have supervision over the city's civil service.

The assessed valuation of taxable property, in the city, in August 1906 was $201,585,127, of which $157,611,560 represented realty and $43,973,567 personality. The valuation is about 60 % of the actual value. The tax rate for all purposes in that year was $2·26 per $100. According to a special report of the census the cost of the city government of Milwaukee in 1906 was smaller per capita than that of any other city in the country with a population of over 300,000. At the close of the year 1906 the total debt was $8,835,049, and the funded debt was $8,106,500.

History.—The first Europeans known to have visited the site of Milwaukee were Father Jacques Marquette, the Jesuit missionary, and his companion, Louis Joliet, who on their return in the autumn of 1673 to the mission of St Francis Xavier at De Pere from their trip down the Mississippi, skirted the west shore of Lake Michigan in their canoes from Chicago northward. Milwaukee Bay is distinctly marked in the map attributed to Marquette, the original of which is now in the Jesuit College at Montreal, Canada; it was discovered in a convent in Montreal by Felix Martin (1804–1886), of the Society of Jesus, and was copied by Parkman. In 1679 La Salle and his party probably stopped here on their way south, and in the Jesuit *Relations* of that year the name Milwaukee first appears, as "Millioke." This, and the various other spellings of the name, attempted to reproduce the Indian name of the village here, which Kelton thinks was pronounced Minewagi and meant "there is a good point" or "there is a point where huckleberries grow," in allusion to the fertile soil. Doubtless the *coureurs du bois* who at this time began to frequent the Wisconsin forests, touched at the bay many times within the succeeding years as the place was known to be a favourite rendezvous of the Fox (or Outagamie) Indians. In 1699–1700 Father St Cosme, a Recollet friar, was here, finding bands of Mascoutens, Fox, Winnebago and Potawatomi. He called the river "Melwarik," "Melwarck" and "Meliwarik."

For more than half a century no definite reference to the place can be found. In 1760 its advantageous situation attracted the adventurous trader, Alexander Henry, the first Englishman known to have visited the spot. Three years later (1763) there was a French fur-trading post here, but it is uncertain just when it was established or how long it was maintained. In 1795 Jacques Vieau, a Frenchman in the employ of the North-Western Fur Company, established a permanent post here, which seems to have continued, under his direction, with practically no interruption until 1820, when it was superseded by that of Astor's American Fur Company. Vieau built a dwelling and a warehouse and conducted extensive trading operations. In 1818 there joined the settlement a young Frenchman named Laurent Solomon Juneau (1793–1856), who married one of Vieau's daughters and eventually bought out his business. Juneau and several others who arrived at about the same time built homes on the east side of the river near the foot of the present Wisconsin Street. Vieau's house and store was at this time on the south side. Milwaukee was on the direct route of travel between Fort Dearborn (Chicago) and the flourishing settlement at Green Bay, and at once after the treaties between the United States and the Menominee in 1831 and 1833 for the extinguishing of the Indian titles, settlers began to come to the neighbourhood. A map of 1830 shows a small settlement on "Milwalky Bay"; and the treaty of the 8th of February 1831 speaks of the "Milwauky or Manawauky River." Morgan L. Martin (1805–1887) of Green Bay, a lawyer and judge, and a delegate to Congress in 1845–1847 from Wisconsin territory, explored the harbour facilities in 1833 and made a map of the place which he called "Milwaukie." He entered into an agreement later in the same year with Juneau and Michael Dousman for its development. A saw-mill was built in 1834, and settlers began to arrive. The east side was platted in the summer of 1835, and very soon afterward the plat of a settlement on the west side was also recorded, Byron Kilbourn being the chief projector and proprietor of the latter. The rival settlements, officially known as Milwaukee East Side and Milwaukee West Side, bore the popular designations of "Juneautown" and "Kilbourntown." A third settlement, begun on the south side by George H. Walker and known as "Walker's Point," was subsequently platted independently. The rivalry between the east and west side towns was intense, the plats were so surveyed that the streets did not meet at the river, and there were bitter quarrels over the building of bridges. Milwaukee county was set off from Brown county in 1834, and in 1836 the establishment of townships was authorized. Under this act the east and west sides were independently incorporated in February 1837. A realization that the continuation of independent and rival corporations retarded growth eventually led to a compromise by which the two were united as two wards of the same village in 1839, the autonomy of each being still recognized by an odd arrangement whereby each maintained practically independent management of its finances and affairs. Walker's Point, the south side, was annexed as a third ward in 1845, and in 1846 the three wards were incorporated as the city of Milwaukee, of which Solomon Juneau was elected first mayor. The influence of this early rivalry may be seen in several provisions of the existing city charter.

About 1840 a strong tide of immigration from Germany set in, continuing steadily for a half-century. It was greatly accelerated by the German revolutionary movements of the late 'forties, which added to the city's population a considerable element of educated Germans of the upper class. From this time the Teutonic character of the population was marked. The first newspaper, the *Advertiser*, began publication in 1836; the first bank was established in 1837. In 1839 George Smith and Alexander Mitchell established the Fire and Marine Insurance Company Bank. As "Mitchell's Bank" this institution was known for forty years as one of the strongest banking houses west of the Alleghanies, its notes passing at par during panics in which even the government issues were depreciated. Through it the Chicago Milwaukee & St Paul and other western railways were financed. Beer was first brewed in Milwaukee in 1840. Milwaukee was connected with Chicago by telegraph in 1849, and by railway in 1856. Previous to this, however, in 1851, the first train ran over the Chicago Milwaukee & St Paul railway to Waukesha, and in 1857 through trains were run over the same road to the Mississippi at Prairie du Chien.

See J. S. Buck, *Pioneer History of Milwaukee* (4 vols., Milwaukee, 1876–1886); A. C. Wheeler, *Chronicles of Milwaukee* (Milwaukee, 1861); E. S. Mack, "The Founding of Milwaukee" in *Proceedings of the State Historical Society for 1906* (Madison, 1907); and L. M. Larson, *Administrative History of Milwaukee* (Madison, Wisconsin, 1908).

MIMETITE, a mineral consisting of lead chloro-arsenate, $(PbCl)Pb_4(AsO_4)_3$, crystallizing in the hexagonal system and closely resembling pyromorphite (*q.v.*) in appearance and general characters. The arsenic is usually partly replaced by equivalent amounts of phosphorus, and there may thus be a gradual passage from mimetite to pyromorphite. The two species can, as a rule, only be distinguished by chemical analysis, and because of their close resemblance the less frequently occurring chloro-arsenate was named mimetite or mimetesite, from Gr. μιμητής, imitator. Crystals of pyromorphite though usually optically uniaxial are sometimes biaxial, but in mimetite this anomalous character is almost always present; a cross-section of a hexagonal prism of mimetite shows a division into six optically biaxial sectors or a complex lamellated structure. In colour mimetite is usually yellow or brown, rarely white or colourless; the lustre is resinous to adamantine. The hardness is $3\frac{1}{2}$, and the specific gravity 7·0–7·25. Like pyromorphite, mimetite is found in the upper parts of veins of lead ore, where it has been formed by the oxidation of galena and mispickel. When found in large amount it is of importance as an ore of lead. The best crystallized specimens are those from Johanngeorgenstadt in Saxony and Wheal Unity in Cornwall. It was formerly found in considerable amount at Dry Gill in Cumberland, as six-sided barrel-shaped crystals of a brownish-red or orange-yellow colour and containing a considerable proportion of phosphoric acid; this variety has been called campylite, from Gr. καμπύλος, curved, on account of the remarkable curvature of the faces of the crystals. (L. J. S.)

MIMICRY, in zoology, the deceptive and advantageous resemblance presented by defenceless and edible species of animals to other species of animals living in the same locality, which are harmful or distasteful and are consequently avoided by all or by a majority of the enemies of the class to which the mimetic and usually the mimicked species belong. Mimicry is a special form of protective resemblance, differing from ordinary protective resemblance as exemplified by the similarity of the resting goat-sucker to a piece of bark or of leaf- and stick-insects to the objects after which they are named, in that the imitated object belongs to the animal kingdom and not to the vegetable kingdom or to inorganic nature. Although, like protective resemblance, quite independent of affinity between the organisms concerned in the likeness, mimicry occurs most commonly between animals structurally similar, and therefore related, to one another, the relationship may be close or remote. For instance, the commonest and best-known cases are found in insects where both mimic and model may belong to the same genus, sub-family, family or order, or to different orders. More rarely it occurs between members of distinct classes of the same sub-kingdom, *i.e.* between spiders and ants or spiders and beetles; yet even in this case both mimic and model have in common certain fundamental structural points to which the finishing touches completing the mimetic likeness are superadded. Still more rarely mimicry exists between totally unrelated species like caterpillars and snakes or spiders and snails. But in no case does it appear that the modifications in shape and colour, which contribute to bring about a mimetic resemblance, are greater and more elaborate than those which result in the simpler examples of ordinary protective resemblance.

The principle of protective resemblance, for which the term mimicry, as above defined, was originally employed, was first explained by H. W. Bates. Subsequently the meaning of the word was extended by F. Müller to include cases of mutual resemblance between two or more noxious species inhabiting the same area. Hence the resemblances belonging to the first category are commonly termed "Batesian mimicry," and those belonging to the second category "Müllerian mimicry," or more properly "Müllerian resemblance." The difference between the two phenomena is essential and evident; but without experimental information as to palatability it is impossible to know with certainty to which of the two a particular case of mimicry is to be assigned. Over and over again extended knowledge on this point and inferences drawn from other facts have shown the certainty or probability of examples of mimicry being in reality "Müllerian," which were previously accepted without question as "Batesian." A simple illustration will serve to explain these two aspects of mimicry and to show the advantage in the struggle for existence that mimicry confers upon the species concerned.

There is a common English Syrphid fly (*Eristalis tenax*) known as the drone-fly from its resemblance to a large hive or honey bee. Honey bees are protected from a large number of insect enemies because they sting and are distasteful. Insect-eating birds soon learn to associate distastefulness with the size, form and colour of the bees, and consequently leave them alone after one or more trials. But flies of the drone-fly kind cannot sting, and, so far as is known, are perfectly innocuous and edible. The advantage to the fly of its deceptive resemblance to the bee is theoretically perfectly evident and practically can be demonstrated by experiment. It is in the first place a matter of common knowledge that human beings who have been taught to avoid handling bees invariably fear to touch drone-flies, unless specially trained to distinguish the one from the others. Moreover, Professor Lloyd Morgan found that young birds that had tasted and rejected workers of the hive bee as unpalatable subsequently refused to taste not only drones, which have no sting, but also drone-flies. So far as our information at present extends the resemblance between these two insects is a simple case of mimicry in the Batesian sense of the word. That is to say, an edible species is protected by resembling one that is inedible. But if it be discovered, as is possible, that the drone-fly is also inedible, the mimicry must be ascribed to the Müllerian category, and the reason for it becomes less evident. In what way, it may be asked, are two or more distasteful species of insects, occurring in the same locality, benefited by resembling each other? The ingenious explanation suggested by Fritz Müller for similar cases met with in butterflies is probably the true answer. This explanation depends upon what is now an experimentally demonstrated fact that insectivorous birds, and probably other animals, have no instinctive knowledge of what insects are edible and what inedible. This knowledge is acquired by experience; and since it is not, at all events as a rule, taught by the first taste to any individual bird, it is reasonable to infer that a considerable amount of injury, sufficient to disable if not to kill, is annually inflicted upon insects belonging to species protected by distastefulness or kindred qualities. Now insects that possess noxious attributes, and the same is true of other animals, usually have a conspicuous warning coloration which appeals to the eyes of enemies and helps them to remember more easily the cause of an unpleasant experience, helps in fact to establish a psychical association between a particular style of coloration and a nasty taste or a painful wound. This being so, it is evident that if all the distasteful species in a given area are differently coloured, some individuals of all the species will be annually sacrificed to the experimental tasting of inexperienced foes before the numerous lessons have been learnt. But if all the species in question resemble each other the resemblance will be mutually beneficial to them because the association between the two attributes they have in common, namely distastefulness and a particular scheme of colour, will be rapidly established. One lesson only, instead of many, has to be learnt; and once learnt at the expense of a few individuals of one or two species it will thereafter be applied indiscriminately to all. This type of mimicry has been well defined by Professor E. B. Poulton as the unification of warning colours.

Since belief in the adequacy of the two theories, above outlined, to account for the facts they profess to explain, depends ultimately upon the testimony that can be brought forward of the usefulness of warning characters, of the deception of mimicry and of the capacity for learning by experience possessed by enemies, it is necessary to give some of the evidence that has been accumulated on these points. (1) In South America there are butterflies formerly grouped as Heliconidae which are conspicuously coloured, slow of flight and abundant in individuals so as to be susceptible of easy capture. They possess scent glands. By observation and experiment it was discovered independently by Messrs Bates, Wallace and Bell that they are not attacked by birds nor by many other enemies that prey upon unprotected Lepidoptera. (2) As the result of a series of trials made in Calcutta F. Finn came to the conclusion that young birds have no instinctive knowledge of the unpalatability of distasteful insects, but that experimental tasting soon teaches them to recognize and avoid species they have previously rejected with dislike, and that having once learnt the lesson they long remember it. (3) That birds may also be deceived by insects that mimic those they have found to be uneatable has been shown by the above-quoted experiment with the drone-fly and the honey-bees made by Professor Lloyd Morgan. He also found that chickens that had been given meal moistened with quinine and placed upon glass slips banded black and yellow, afterwards refused to touch meal moistened with water and spread upon the same slips, although they had previously eaten it with readiness off plain coloured slips. With two exceptions, these chickens that had learnt to associate black and yellow banding with a bitter taste also refused to touch the caterpillar of the cinnabar moth (*Euchelia jacobaeae*), which is banded with these colours. Moreover, young birds that had been taught by experience that these caterpillars are uneatable also left wasps untouched. (4) Guy Marshall once offered to a baboon a distasteful butterfly (*Acraea anemosa*), holding the insect in such a way as to display its bright red and black markings to the monkey. It was taken but rejected after being tasted. A specimen of another butterfly (*Precis sesamus*) which mimics the *Acraea* was then offered in the same manner. The baboon took it, held it in her hands for a few moments, and then let it escape uninjured without trying to taste it. But when another butterfly of the same species, but with the wings cut off, was offered to her she promptly ate it without showing any sign of dislike. The results of this experiment with the baboon and of those with the birds are precisely what would be expected if the theory of mimicry is true. Experiments to test distastefulness have also been made with various kinds of insectivorous Arthropoda, like spiders and mantises. These experiments have shown that Arthropods also have their likes and dislikes in the matter of insect-food and frequently refuse to eat insects which are warningly coloured and are distasteful to vertebrated enemies. They appear, however, to have no appreciation of mimetic and warning colours, and have therefore not influenced in any way the evolution of mimetic resemblances dependent upon hues and patterns. Nevertheless, as explained below, it seems to be highly probable that ant-imitating insects and spiders, when the resemblance is dependent to a greater extent upon size, shape and movement than upon tint, have acquired their mimetic likeness especially to protect them from the attacks of such insect-enemies as predaceous wasps of the family Pompilidae, flies of the family Asilidae, and from so-called parasitic hymenoptera of the family Ichneumonidae, as well as from other insect-eating Arthropods.

The term mimicry has also been applied to resemblances of a different kind from the two enumerated above—resemblances, that is to say, by which predaceous species are supposed to be enabled to approach or mix without detection with animals they prey upon or victimize in other ways. To this end the resemblance may be actually to the species victimized or preyed upon or else to a species which the species preyed upon does not fear. This phenomenon is termed " aggressive mimicry " as opposed to the Batesian and Müllerian phenomena, which are termed " protective mimicry." A few possible cases of aggressive mimicry are enumerated in the following summary of some of the recorded cases of mimicry in different classes of the animal kingdom; but the phenomenon is of comparatively rare occurrence, and the supposed instances may be susceptible of other interpretations, excluding them altogether from mimicry, or bringing them under the Batesian or Müllerian interpretation of the phenomenon.

Among mammalia there are no certain cases of mimicry known. It has been claimed that the resemblance between some of the Oriental tree-shrews of the genus *Tupaia* and squirrels comes under the category of aggressive mimicry, the tupaias being enabled by their likeness to approach and pounce upon small birds or other animals which, mistaking them for the vegetable-feeding squirrels, make no effort to get out of the way. But this hypothesis cannot be accepted as furnishing a satisfactory explanation of the likeness. For in the first place there seems to be no good reason for thinking that the Tupaias feed to any considerable extent upon prey of that kind, and in the second place the resemblance is due to characters which may be merely adaptations to a similar mode of life. A long and bushy tail, for instance, is a useful balancer and is a not uncommon feature in mammals which lead an active arboreal life. Similarly the dull coloration of the two sets of animals is very possibly procryptic and serves to hide both shrews and squirrels from enemies. Hence there seem to be good reasons for regarding the likeness in question as due to similarity in habitat and not as mimetic.

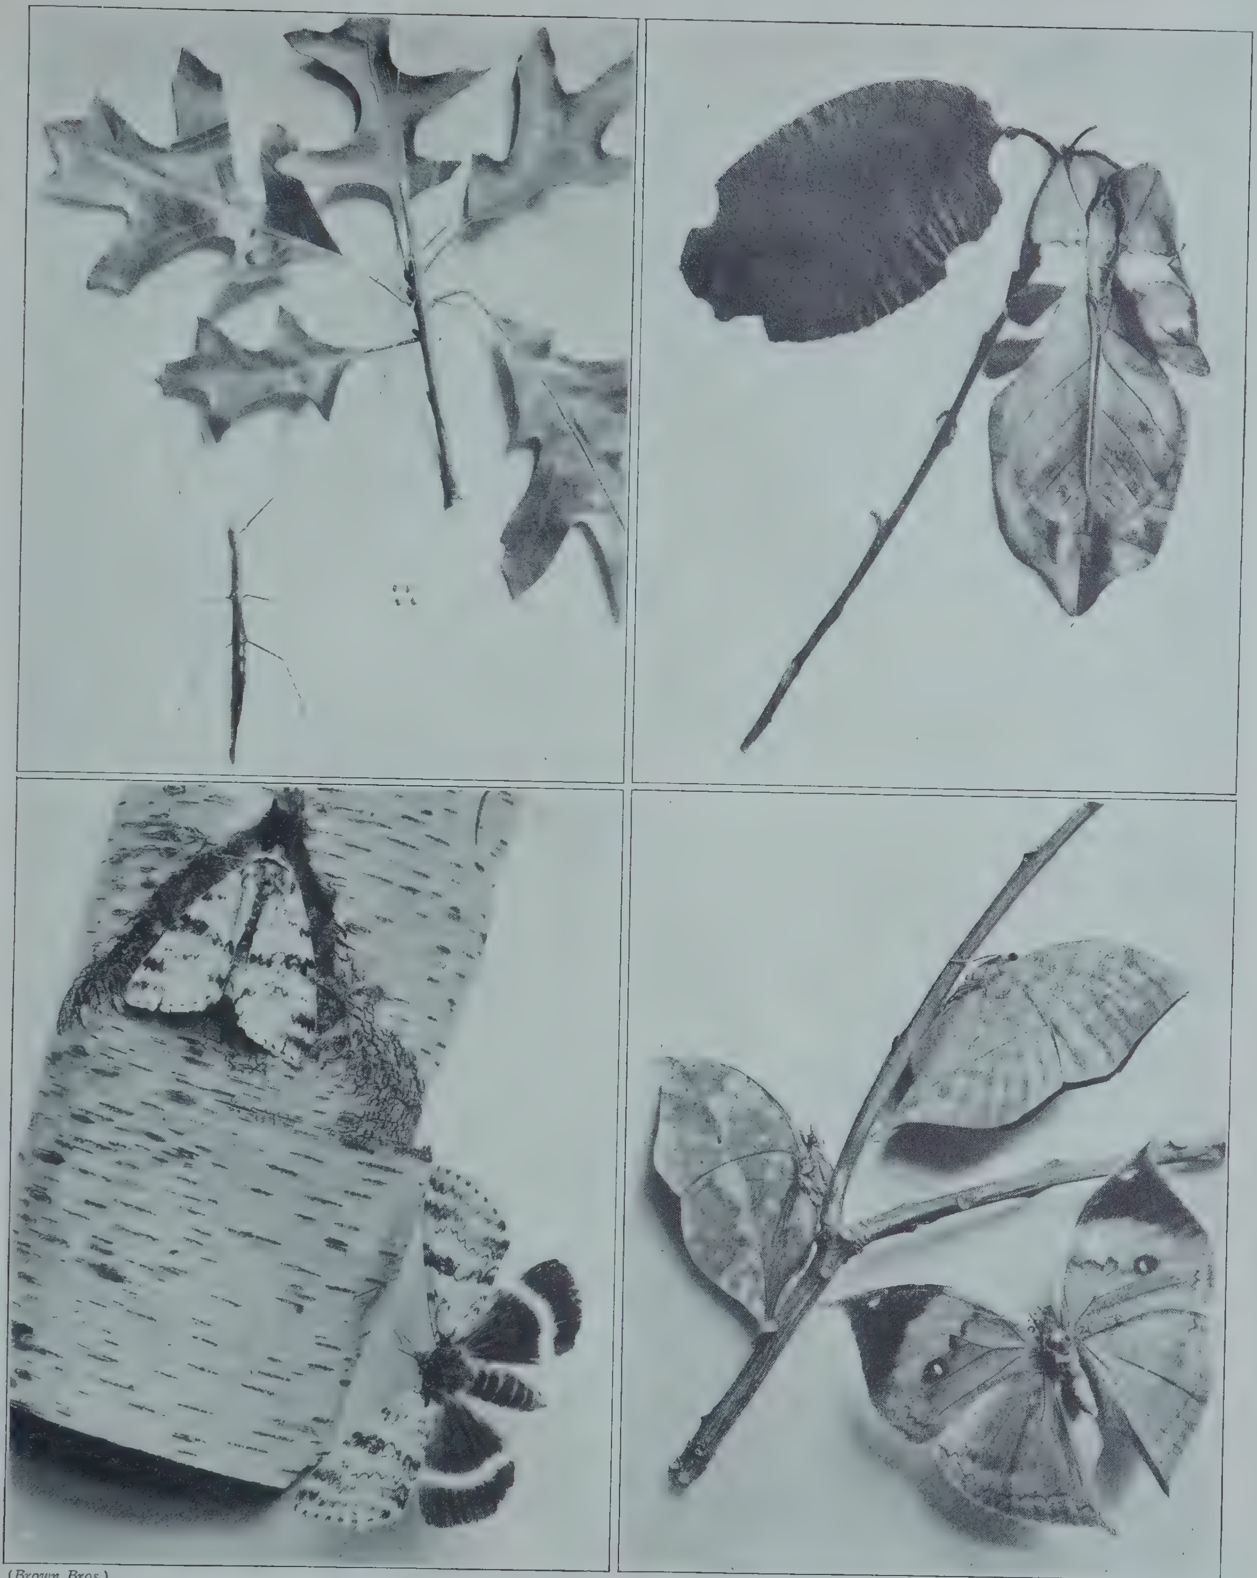
In East and South Africa there is a genus of Mustelidae known as *Ictonyx* (*Zorilla*) which possesses a foetid odour and is warningly coloured with black and white bands after the manner of skunks. There also occurs in South Africa another member of this family (*Poecilogale albinucha*), which is very similarly coloured. It is possible that this resemblance is mimetic in the Batesian sense of the word, and that the *Poecilogale*, if inoffensive, profits by its likeness to the highly offensive and warningly coloured *Ictonyx*. But, on the other hand, *Poecilogale* may itself be a protected form since subcaudal stink-glands are commonly found in species of the weasel tribe. If this be the case the two species probably furnish an instance of true Müllerian mimicry. In South America there is considerable superficial resemblance between the little bush dog (*Speothos venaticus*) of Guiana and Brazil and the large weasel-like animal of the same countries—the tayra (*Galera barbara*). The tayra is, when adult, black beneath and on the legs, and not uncommonly has a considerable quantity of greyish hair on the head. In these particulars, as well as in size and shortness of leg, the dog resembles the weasel; and since there are good reasons for believing that the latter is protected alike by ferocity and stink-glands, it is quite possible that the dog, of unusual coloration and form for the Canidae, is protected from the attacks of pumas, jaguars and ocelots by his likeness to the tayra.

A few cases of mimicry have been recorded in birds. The common cuckoo and some other species inhabiting Africa and Asia closely resemble sparrow-hawks. Some cuckoos are singular for their habit of using the nests of smaller birds to lay their eggs in, so that the young may be reared by foster-parents; and it has been suggested that the object of the likeness exhibited to the hawk is to enable the cock cuckoo either to frighten the small birds away from their nests or to lure them in pursuit of him, while the hen bird quietly and without molestation disposes of her egg. The fact that both sexes of the cuckoo resemble the hawk does not necessarily prove this suggested explanation to be false; but if it be true that the smaller passerine birds are duped by the similarity to the bird of prey, it may be that the cuckoos themselves escape molestation from larger hawks on account of their resemblance to the sparrow-hawk. Another species of this group, the black cuckoo of India, apparently mimics the black drongo-shrike (*Dicrurus ater*), the resemblance between the two species being very close. The drongo is a fierce and powerful bird which will not tolerate a strange bird of the size of a cuckoo near its nest, yet on account of its resemblance to the drongo, the hen cuckoo is enabled, it has been claimed, to lay her egg in the nest of the drongo, which mistakes the cuckoo for one of its own kind. In this case also both sexes of the cuckoo mimic the drongo, whereas according to the theory it would be necessary for the hen bird alone to do so. This suggests that the resemblance to the pugnacious drongo may be beneficial in protecting the defenceless cuckoo from enemies.

Some observations, however, of Guy Marshall on the inedibility of certain birds suggest that the resemblance between cuckoos and hawks on the one hand and cuckoos and drongos on the other may be susceptible of another explanation in full agreement with the theory of mimicry as propounded by Bates. He found that a South African drongo (*Dicrurus* (*Buchanga*) *assimilis*) was rejected after one or two attempts to eat it by a hungry mongoose (*Herpestes galera*) which had been starved for purposes of the experiment. The drongo is blue and black and is, he believes, warningly coloured. The same mongoose also refused to eat a kestrel (*Cerchneis rupicoloides*) and a hobby (*Falco subbuteo*), although it devoured certain

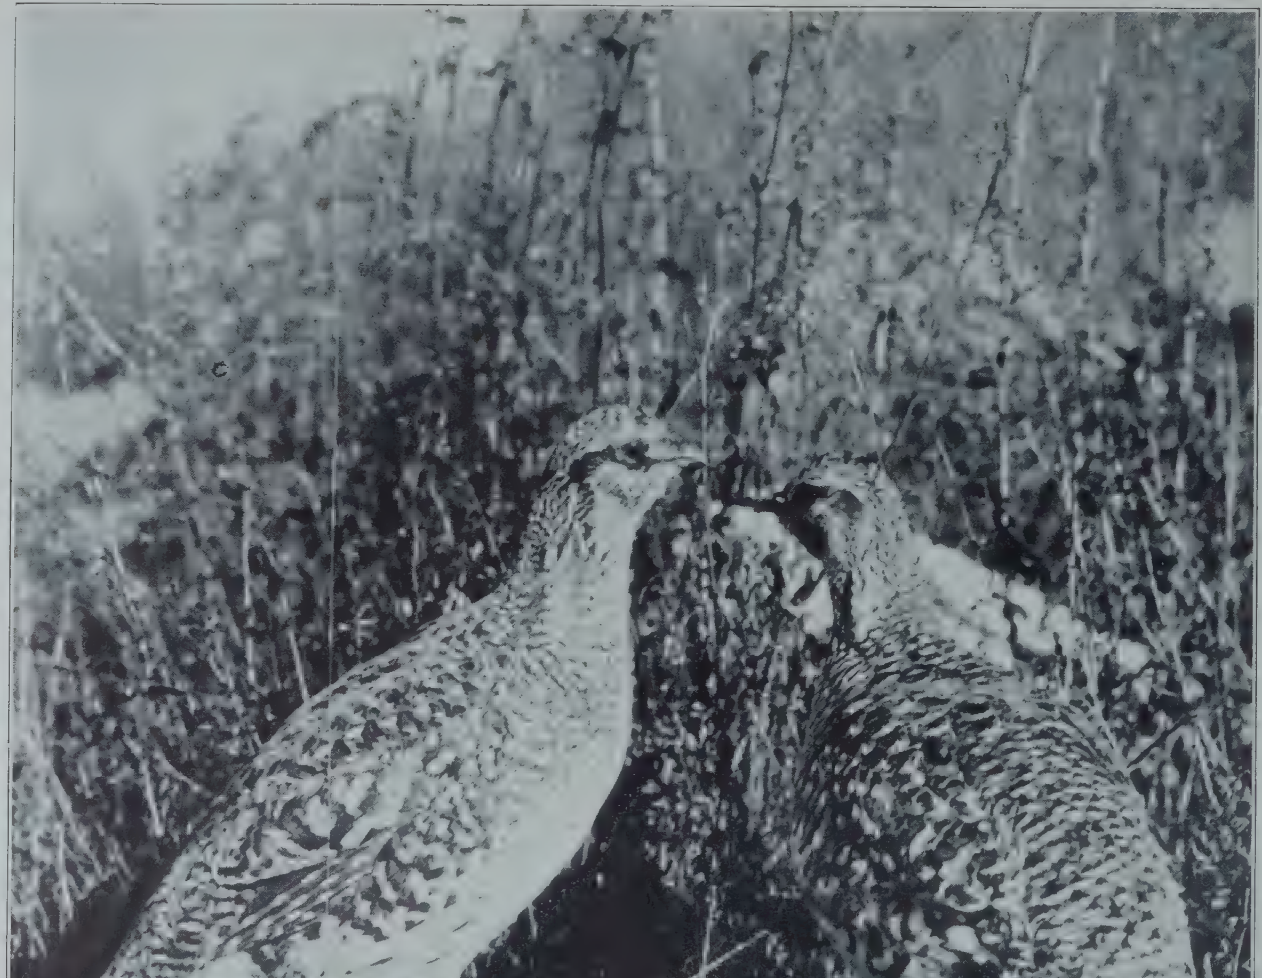
MIMICRY

PLATE I.



(Brown Bros.)

FIG. 1. The "Walking Stick" or "stick-bug" clinging to an oak twig is hard to detect. Another specimen is shown separately for comparison. FIG. 2. The "Walking Leaf" found in India is an extreme example of protective mimicry. FIG. 3. Moth resting on trunk of birch tree. A flying moth at the side. FIG. 4. Two butterflies resting on twigs, simulating leaves; with third butterfly in flight, for comparison. See COLOURS OF ANIMALS, Vol. 29.



(*Ewing Galloway.*)

Prairie Chicken, Canada, showing how the colouring simulates the broken lights and shadows of the underbrush and grass. A further discussion of this interesting subject will be found in the article COLOURS OF ANIMALS, Vol. 29. Its extension to the field of modern warfare is dealt with in the article CAMOUFLAGE in the same volume.

other birds that were given to it. It is clearly possible, therefore, that cuckoos which mimic drongos and hawks may be protected from those enemies which find these birds distasteful.

One of the most perfect cases of mimicry in birds is presented by a Madagascar thrush or babbler (*Tylas eduardi*), which resembles feather for feather a shrike (*Xenopirostris polleni*), from the same island. The *Tylas* has departed from the normal coloration of its group to take on that of the shrike, a comparatively powerful and pugnacious bird. Analogous cases are supplied by the mimicry that exists between some of the orioles (*Mimeta*) and the friar-birds (*Philemon* or *Tropidorhynchus*) of the Austro-Malayan Islands. The friar-birds are noisy and pugnacious species of the group of honey-eaters, and mob hawks and other birds of prey, which leave them unmolested. The general style of coloration of orioles is gaudy yellow and black, rendering them invisible in sunlit foliage, and quite different from the more sombre hues of the friar-birds; but in the islands of Bourou, Timor and Ceram the orioles have not only assumed the tints of friar-birds in general, but in each of the islands named a species of oriole has acquired the little peculiarities in colour of plumage possessed by the friar-bird of the same locality. There seem to be no reasons for doubting that these are cases of genuine protective mimicry.

Apparently the only instances of mimicry known amongst reptiles occur amongst snakes; and in all the cases quoted by Wallace harmless snakes mimic venomous species. In tropical America the genus *Elaps*, which is both poisonous and warningly coloured, is a model for several innocuous snakes. In Guatemala *Elaps fulvus* is mimicked by *Pliocerus equalis*; in Mexico *Elaps corallinus* by *Homalocranium semicinctum*, and in Brazil, *Elaps lemniscatus* by *Oxyrhopus trigeminus*. In South Africa the harmless egg-eating snake (*Dasypeltis scaber*) is very like the Cape adder (*Bitis atropos*); and in Ceylon the harmless Colubrine *Lycodon aulicus* is alleged to mimic *Bungarus ceylonicus*, an ally of the deadly krait of India. Considering, however, the numbers of venomous and innocuous snakes that occur in most tropical countries, it might be supposed that mimicry in this order of reptiles would be of commoner occurrence than appears to be the case. It must be remembered, however, that apart from size and colour all snakes resemble each other in a general way in their form and actions. They present a strong family likeness which is not found in any other terrestrial vertebrated animals with exception of some lizards and possibly Caecilians amongst the Amphibia. So close indeed is the similarity that many monkeys, apes and human beings have an apparently instinctive fear of all snakes and do not discriminate between poisonous and non-poisonous forms. Hence it may be that innocuous snakes are in many instances sufficiently protected by their likeness in shape to poisonous species that close and exact resemblance in colour to particular species is superfluous.

As a possible instance of mimicry in fishes, A. T. Masterman recalls the fact that two species of weever (*Trachinus draco* and *T. vipera*), have the same habitat in British waters as certain species of soles (*e.g. Solea vulgaris*). The weevers are poisonous and the venom is concentrated principally in the six spines of the first dorsal fin. These spines are sharp and connected by a black membrane which projects, when the fish is disturbed, as a danger singal, it is believed, above the surface of the sand in which the fishes lie hid awaiting prey. For protective purposes soles, which are edible, also lie buried in or on the sand which they match in colour, with the exception of the right or upper pectoral fin which has a large black patch. When disturbed the soles raise this black fin and, as a rule, hold it rigid so that it becomes a very conspicuous object. If the view that the sole is protected by the blackness of the pectoral fin resembling the blackness of the dorsal fin of the weever, be correct, these fishes furnish an instance of Batesian mimicry. Furthermore, there is a common littoral fish in the Mediterranean (*Uranoscopus scaber*), belonging to the same family as *Trachinus*, exhibiting the same habits and living on the same ground, which also has a jet black erectile dorsal fin, and is believed to be poisonous. It is probable that the resemblance between *Uranoscopus* and *Trachinus* with respect to the colour of the dorsal fin is mutually beneficial to the two fishes. If so, the likeness must be regarded as an instance of Müllerian mimicry.

It is amongst Arthropods, however—and especially amongst insects—that mimicry, both Batesian and Müllerian, occurs in greatest profusion and perfection.

In insects of the order Orthoptera, departure from the normal in form and colour, carrying with it similarity to other living things, usually takes the line of protective resemblance to parts of plants. This is well exemplified by the leaf-insects (*Phyllium*) and stick-insects (*Bactra*), where the likeness to the models after which they are named is procryptic; and also by various species of tropical Mantidae which resemble flowers for the purpose of alluring insects within striking distance and perhaps also for concealing their identity from enemies. Some cases of genuine mimicry, however, are known in the order. Perhaps the best is that of the Sudanese Locustid (*Myrmecophana fallax*), which is strikingly ant-like. The head is large, the neck slender, the antennae short, and the legs longish, and the appearance of the long stalk-like waist of the ant is produced by a patch of whitish hair on each side of the forepart of the abdomen which has the effect of cutting away the parts of the segments so covered, leaving a narrow dark-coloured median area to represent the waist. This at least is the method of disguise suggested by examination of the dried insect; but representatives of the same or an allied species found in Mashonaland were observed in the living state to be green with the antlike parts represented in black pigment. These parts were quite conspicuous against the green of the plants frequented by the insects, wherever the green portions were rendered invisible by the same background. Ant-mimicry has also been recorded in the case of the larva of one of the Indian species of Mantidae. Again, several species of this order have become profoundly modified in form in imitation of inedible beetles. In the Philippines, a cricket (*Scepastus pachyrhynchoides*), has taken on the shape and coloration of a species of *Apocyrtus*, a hard and inedible weevil (*Curculionidae*); and *Phoraspis*, a kind of grasshopper similarly resembles ladybirds (*Coccinellidae*). A species of beetle (*Caria dilatata*) of this family in Borneo is mimicked by a species of a genus allied to *Gammarotettix* not only in shape and coloration but also in the habit of remaining still when disturbed. In the same island a species of *Gryllacris* mimics *Pheropsophus aquatus*, a "Bombardier" beetle which ejects a puff of volatile formic acid when attacked; and *Condylodera tricondyloides* mimics different species of tiger-beetles (*Cicindelidae*) at different stages of its growth. Finally the larva of one of the Bornean Mantidae, which is a floral simulator in its pupal and adult stages, closely resembles in its black and red coloration the larva of the stinking and warningly coloured bug *Eulyes amoena*.

Comparatively few cases of mimicry in the Neuroptera have been observed. There are records, however, of species of *Mantispa* mimicking the wasp *Polistes* in North America and Borneo and *Belonogaster* in South Africa; and other species of the genus imitate parasitic hymenoptera of the genera *Bracon* and *Mesostenus*.

Coleoptera (beetles) supply instances of mimicry of ants, wasps and Ichneumonids, and some defenceless forms of this order mimic others that are protected. A good illustration of wasp-mimicry is furnished by a large heteromerous beetle (*Coloborhombus fasciatipennis*) from Borneo which is remarkably like a large wasp (*Mygnimia aviculus*) from the same island. The front wings of the wasp have a conspicuous white patch near the tip and a patch similar in size and colour is present on the wings of the beetle, which, unlike the majority of beetles, habitually keeps its wings extended, and since the elytra are exceptionally short the wings are not covered by them when folded. The resemblance also extends to the general form of the body and to the length and thickness of the wings and antennae. The elytra are equally reduced, and apparently for the same purpose, in an Australian Longicorn beetle (*Esthesis ferrugineus*), which, like so many wasp-like Hymenoptera, has the body banded red and black. This beetle probably mimics the Australian hornet (*Abispa australis*). In the European Longicorn (*Clytus arietis*), on the other hand, the elytra are of normal length and are banded with yellow stripes. The beetle, moreover, is of slender build and all its actions are suggestively wasp-like. This may, however, be an instance of Müllerian rather than of Batesian mimicry, the beetle being itself inedible; for Shelford has stated his conviction that the Bornean representatives of the sub-family (Clytinae), to which *Clytus arietis* belongs, are all highly distasteful and are warningly coloured, as are members of this sub-family from other parts of the world.

In the Philippine Islands several species of Longicorns of the genus *Doliops* mimic hard inedible weevils (*Curculionidae*) of the genus *Pachyrhynchus*. The antennae of these weevils are short and end in a knob; those of the Longicorns are very much larger, but the weevil-like look is produced by the presence of a knob-like swelling upon the third joint, the terminal portion of the antenna being so extremely fine as to be almost invisible. Similar modification of the antennae in the Longicorn *Estigmenida variabilis* brings about the resemblance between this beetle and a beetle, *Estigmena chinensis*, one of the Phytophaga of the family Hispidae. Numerous instances of mimicry in this order of insects have recently been recorded from Borneo by R. W. C. Shelford, a large number of them being in all probability Müllerian.

Instances of ant-mimicry, unique in the method employed to bring about the resemblance, are supplied by some insects of the Homopterous group of the Rhynchota, belonging to the family Membracidae. In one of these (*Heteronotus trinodosus*), the dorsal area of the forepart of the thorax is developed into a plate which projects backwards over the body of the insect, which retains its normal form, and conceals all but the head, wings and legs. This shield if shaped in such a manner as to resemble closely the body of an ant, the median portion of the shield being deeply constricted in imitation of the waist and the terminal portion sub-globular like the abdomen of the ant. This insect comes from Central America. Still more curious is the mimicry of another of these insects from Venezuela which is found in company with a leaf-cutting ant (*Oecodoma cephalotes*) of that country. When pursuing their operations of leaf-storage, these ants present the appearance of a crawling crowd of leaf-particles, fragments of leaves being carried by the insects in such a way as to conceal to a great extent the insect underneath, of which little more than the dark coloured legs project beyond the burden. The immature form of the above-mentioned species of Membracidae mimics both ant and leaf-particle. The legs and lower part of the body are dark coloured, but the dorsal surface of the thorax and abdomen is coloured green and is raised so as to form a crest with jagged edges exactly reproducing the irregular margin of a fragment of leaf cut out by the mandibles of the ant. In Borneo the Homopteron *Issus bruchoides* mimics a species of Curculionid beetle of the genus *Alcides*.

In the Hemipterous group of the Rhynchota ant-mimicry is illustrated by the larva of a British species of Reduviidae (*Nabis lativentris*) in which the forepart of the abdomen is furnished on each side with a patch of white hairs leaving a central narrow dark portion in imitation of the waist of the ant; and also by an East African species (*Myrmoplasta mira*) which in its general form exhibits a close resemblance to an ant (*Polyrrhacis gagates*) which occurs in the same neighbourhood. Another instance in this group is supplied by a Bornean species of Reduviidae which mimics a species of the genus *Bracon*, one of the parasitic Hymenoptera.

Typical dipterous insects (flies) closely resemble in general form aculeate Hymenoptera belonging to the families of bees and wasps. The changes in colour and structure required to complete the resemblance to particular species are comparatively slight and much less complicated than those needed to produce a likeness to other protected insects. Hence we find that the majority of flies that mimic insects of other orders have bees or wasps for their models. Many of the Syrphidae are banded black and yellow and present a general resemblance to wasps, especially when they alight, the resemblance being enhanced by a twitching action of the abdomen imitating the similar action so familiar in species of stinging hymenoptera. These flies are characterized by a peculiar method of flight. They commonly hang poised in the air, then dart with lightning swiftness to another spot and poise themselves again. This habit, the origin of the name "hover-flies," is probably connected with their mimetic coloration. If they flew like ordinary flies their resemblance to Hymenoptera would be obscured by the rapidity of their flight and they might be caught on the wing by insectivorous birds or other insects; but when poised they display their coloration. When the latter is lost during flight, the rapidity of their movement defies pursuit. The particular likeness to a honey-bee presented by one member of this family, the drone-fly (*Eristalis tenax*), has been already referred to. But the likeness probably goes deeper than superficial resemblance that appeals to the eye; for spiders which distinguish flies from bees by touch and not by sight, treat drone-flies after touching them, not in the fearless way they evince towards bluebottles (*Calliphora*), but in the cautious manner they display towards bees and wasps, warily refraining from coming to close quarters until their prey is securely enswathed in silk. This forcibly suggests that the drone-fly mimics a honey-bee not only in appearance but also in the feel of its hairs or the nature of its buzz. Other flies of the genus *Volucella*, larger and heavier in build than *Eristalis*, resemble humble-bees in colour and form, and it was formerly supposed that the purpose of this similarity was to enable the flies to enter with impunity the nests of the humble-bees and to lay their eggs amongst those of the latter insects. But it has been ascertained that the species of *Volucella* which behave in this manner also visit for a like purpose the nests of wasps, which they do not resemble. Hence it is probable that this case of mimicry is purely of a protective and not of an aggressive nature and serves to save the flies from destruction by insectivorous enemies. The same explanation no doubt applies to the mimicry, both in Borneo and South Africa, of hairy bees of the family Xylocopidae by Asilid flies of the genus *Hyperechia*, and also to other cases of mimicry of Hymenoptera as well as of inedible beetles of the family Lycidae by Diptera. Numerous other cases of mimicry between Diptera and Hymenoptera might be cited.

The Lepidoptera furnish more instances of mimicry, both Batesian and Müllerian, than any other order of insects. In the majority of cases both model and mimic belong alike to the Lepidoptera, and it is often uncertain whether both are inedible (Müllerian mimicry) or whether inedibility is the attribute only of the model (Batesian mimicry). A large number of cases that were formerly regarded as belonging to the latter category are now suspected of belonging rather to the former. Sometimes Lepidoptera mimic protected members of other orders of insects—such as Coleoptera, Hymenoptera and Hemiptera; but perhaps the most singular illustrations of the phenomenon known in the order are exemplified by the larvae of the hawk-moth *Chaerocampa*, which imitate the heads of snakes. Professor Poulton long ago suggested, and supported the suggestion by experimental evidence on a lizard, that the larvae of two British species, *C. elpenor* and *C. porcellus*, are protected by the resemblance to the heads of snakes presented by the anterior extremities of their bodies which are ornamented with large eye-like spots. When the larvae are disturbed the similarity is produced with startling suddenness by the telescopic contraction of the anterior segments in such a manner as to suggest a triangular, pointed head with two large dorsal eyes. Subsequent observers (A. Weismann, Lady Verney) have shown by experimenting upon birds that this suggestion is correct; and Guy Marshall found that baboons which are afraid of snakes are also afraid of the snake-like larva of the South African *Chaerocampa osiris*. Finally Shelford states that the anterior end of a Bornean species (*C. myodon*) offers a striking and detailed resemblance to the head of a snake (*Dendrophis picta*).

Instances of ant-mimicry in this order are sometimes confined to the larval stage. The early larval stage of the "Lobster Moth" (*Stauropus fagi*), for example, presents a general resemblance, due to a combination of shape, colour, attitude and movements, to black ants, the swollen head and the caudal disk with its two tentacles representing respectively the abdomen and antenna-bearing head of the model. A parallel case of mimicry exists at Singapore between the larva of a Noctuid moth and the common red tree-ant (*Oecophylla smaragdina*). In this case also the posterior end of the larva represents the anterior end of the ant. Another instance of mimicry affecting the larval form is supplied by the moth *Endromis versicolor*, the caterpillars of which resemble the inedible larvae of saw-flies. The resemblance that certain moths—*e.g. Trochilium apiforme*, *crabroniforme*—present to bees and wasps is effected in the main by the loss of the scales from the wings, leaving these organs transparent. It is important to note that the scales are present when the moths first emerge from the pupa-case, but are loosely attached and fall off with the first flight.

Of the multitudes of cases of mimicry between different species of Lepidoptera, a few only can be selected for description. These cases, however, have a peculiar interest and importance for they have been studied in fuller detail than any others and the discovery of a particular instance in South America first suggested to Bates the theoretical explanation of this bionomical phenomenon. On the Amazons and in other parts of South America there are butterflies of the group Ithomiinae which are distasteful and have all the characters of specially protected species, being conspicuously coloured, slow of flight, careless of exposure and abundant in individuals. The wings are transparent and are black-bordered and black-barred, the anterior wing having two black bars and the posterior one. This type of colouring is also found in genera of quite distinct sub-families of butterflies, namely in Danainae and Pierinae, as well as in some diurnal moths, all of which occur in the same district as the Ithomiinae. The following species may be cited as instances of this type of pattern: *Methona confusa*, *Thyridia psidii*, *Eutresis imitatrix* and *Dirgenna dero* (Ithomiinae); *Itura ilione* and *I. phenarete* (Danainae); *Dismorphia orise* (Pierinae); *Anthomyza buckleyi* (moth of the family Pericopidae) and *Castnia linus* (moth of the family Castniidae). So alike in form, colour and mode of flight are those Lepidoptera that when on the wing it is almost or quite impossible to distinguish one from the other, and the resemblance between members belonging to different sub-families cannot be assigned to affinity. Microscopical examination of the wings, moreover, has shown that the transparency of the wings, common to all, has been acquired by a different modification of the scales in each of the genera exhibiting the Ithomiine type of coloration. That the Danaine and Ithomiine species are distasteful is known. *Itura*, for example, belonging to the former, has protrusible scent-emitting processes at the end of the abdomen; and *Thyridia* has scent-producing tufts of hair on the edge of the posterior-wing. Bates offered no satisfactory explanation of the resemblance between these two genera and others of the same protected sub-families; but he did not hesitate to ascribe the resemblance to them presented by the Pierine, *Dismorphia* (*Leptalis*) *orise*, to mimicry, believing *Dismorphia* to be unprotected and noting that it departed widely in the matter of coloration from typical members of the sub-family to which it belongs. Although mimicry in the Lepidoptera has been carried to a greater extreme in South America than in any other country of the world, remarkable instances of it have taken place in the Ethiopian and Oriental regions. A classical and highly complex case first investigated and explained by R. Trimen is that of *Papilio dardanus* which is widely distributed in Africa and is represented by several sub-species or geographical races. The most primitive of these is *antinorii* from Abyssinia, which is non-mimetic and has the two sexes nearly alike. The males of the other sub-species are much like the males of *antinorii*; but the females are widely different and mimic various species of inedible butterflies belonging to the protected groups of the Danainae and Acraeinae. One of these sub-species, *merope*, which ranges from the west coast to Victoria Nyanza, is polymorphic and occurs under three forms, namely (*a*) *hippocoon*, which mimics the Danaine *Amauris niavius*; (*b*) *trophonius*, which mimics the Danaine *Limnas chrysippus*; (*c*) *planemoides*, which mimics the Acraeine *Planema poggei*. Oddly enough one or more of these forms may occur in other sub-species. For example, the sub-species *cenea* which occurs in south and south-east Africa not only has the form *cenea* mimicking two Danaines, *Amauris echeria* and *A. albimaculata*, but also the *hippocoon* form which resembles a local race of *Amauris niavius*, known as *dominicanus*. The sub-species *polytrophus* from the Kikuyu Escarpments also has the *planemoides* and *cenea* forms and another form *trimeni*, which is intermediate between the unmodified female of *antinorii* and *hippocoon*, and like the latter is mimetic of *Amauris niavius dominicanus*. Finally the sub-species *tibullus* from the east coast has the *cenea*-form, the *trimeni*-form and probably the *planemoides*-form. The study of this intricate case is not yet completed and it is at present unknown whether it is an instance of Batesian or Müllerian mimicry. Special attention may be drawn to two phenomena connected with it, both of not uncommon occurrence in mimetic Lepidoptera. The first is the occurrence of mimicry only in the female sex. The reason for this is to be found in the greater need of protection of the female which is slower in flight than the male and is exposed to special danger of attack when resting to lay her eggs. The second noteworthy phenomenon is the mimicry of more than one protected species by members of a single species. This is a not uncommon occurrence, and in the case of Batesian mimicry the explanation is probably this. When an edible species gains protection by mimicking a distasteful one, there is a likelihood of its increasing in numbers until it equals or surpasses its model in this respect. Were this to take place the purpose of the mimicry would be abortive, because enemies would probably not refrain from slaughter if even every alternate capture proved palatable. It is advantageous therefore that the numbers of the mimetic species should be fewer than those of the model; and this appears to be achieved in some cases by the individuals of the mimetic species dividing themselves between two or more models

Spiders furnish numerous instances of mimicry. Though simple in kind, many of these are as perfect illustrations of the phenomenon as any found in the animal kingdom.

Amongst the orbweavers of the family Argyopidae there are species belonging to the genera *Cyclosa* and *Cyrtophora* which closely resemble small snail-like gastropods as they cling to the underside of leaves with their legs drawn up. Other members of the same family—like *Araneus coccinella*, and *Paraplectana thorntoni*—imitate beetles of the family Coccinellidae which are known to be distasteful; and certain genera of the family Salticidae (*Homalattus* and *Rhanis*) closely resemble small hard-shelled beetles.

The most perfect cases, however, are exhibited by those species which imitate ants. The structural modifications required to convert a spider into the image of an ant are of a more complicated character than those that serve the same purpose in an insect. All insects have the same regional division of the body into head, thorax and abdomen, the same number of legs, a pair of antennae and a segmented abdomen. Spiders on the contrary have no antennae, no separate "head," an unsegmented abdomen and an additional pair of legs. In the majority of ant-imitating spiders the forepart of the cephalothorax is constricted on each side to resemble the neck of the insect, and in many cases the similarity is increased by the presence of a stripe of white hairs which has the optical effect of cutting out an extra piece of integument, exactly as occurs in analogous cases in insects. Narrowing of the posterior portions of the spider's cephalothorax and sometimes of the anterior end of the abdomen reproduces the slender waist of the ant, and frequently transverse bands of hairs represent the segmentation of this region in the insect. The legs become slender and those of the first or of the second pairs are held up and carried in front of the head to simulate the antennae of the ant. Added to this the spiders commonly copy to the life the mode of progression and the restless activities of their models.

The likeness presented varies considerably in degree from a general resemblance to several species, such as is seen in the Salticid spider (*Peckhamia picata*) of North America, to a close similarity to particular species. To this category belong *Myrmarachne plataleoides*, one of the Salticidae, and *Amyciaea forticeps*, one of the Thomisidae which in India imitate and live with the vicious little red ant (*Oecophylla smaragdina*); also *Myrmarachne providens*, which mimics the red and black Indian ant (*Sima rufonigra*); and the South American species of Clubionidae, *e.g. Myrmecium nigrum*, which is an accurate copy of the large black ant (*Pachycondyla villosa*).

Sometimes it is only the males of a species of spider that mimic ants, as in the case of *Ildebaha mutilloides* and *I. myrmicaeformis*, two South American species of the family Argyopidae, in which the females are protected by strong spine-armature. The males are without these protective spines and are exposed to special dangers as they wander in search of the webs of the females. In South Africa too the males of a species of Eresidae (*Seothyra*) resemble and are found in company with a large ant (*Camponotus fulvopilosus*), which is common on the veld. Like the males of *Ildebaha*, those of *Seothyra* wander about by day in search of the females which live concealed in burrows. Many other spiders belonging to the Theridiidae and Linyphiidae also mimic ants; but it is needless to enumerate them, the most perfect examples of this phenomenon being found in the families Clubionidae and Salticidae.

Ant-mimicking spiders have been seen now and again to devour their models. It has therefore been suggested by some and taken for granted by others that the resemblance comes under the category of aggressive mimicry and that the ants are deluded by this resemblance into regarding the spiders as members of their own species. That the ants do not destroy them is certain; but that they are deceived by the superficial similarity of the spiders to themselves is highly improbable, for these insects are capable of distinguishing a strange ant belonging to the same species if it comes from another colony. Moreover, the above-suggested explanation does not coincide with the explanation of the likeness to ants shown by certain insects such as *Myrecophana fallax*, the ant and leaf-like Membracid Homopteron and the larvae of the lobster-moth (*Stauropos fagi*), which are plant-eaters. It is probable that one explanation—namely, that of protection—covers all cases of ant-mimicry; and this explanation lies in all probability in the immunity from the attacks of most insectivorous enemies that ants enjoy, and especially from predaceous wasps of the family Pompilidae which annually destroy thousands upon thousands of spiders to feed their larvae; and since more than one observer has testified to the fear and abhorrence these wasps have of ants, it is needless to look farther for the benefit ant-mimicry is to spiders. These wasps, moreover, also provision their nurseries with caterpillars, grasshoppers and other insects. Hence it may be inferred that the insects which imitate ants profit in the same way that spiders do from this form of mimicry.

In the above-cited historical instance of mimicry amongst some South American Lepidoptera which formed the foundation of Bates' theory, species of butterflies, belonging to the Ithomiine genus *Itura* and the Danaine genus *Thyridia*, both unpalatable forms, resemble each other. This is a very simple case of the possession of the same type of coloration by two or more protected insects inhabiting the same district. The significance of this phenomenon, as already stated, was first explained by Fritz Müller; but although the term "Müllerian mimicry" has been assigned to this and similar instances, they are not strictly speaking cases of mimicry at all but of warning coloration. Poisonous or noxious animals usually have some special advertising attribute, sometimes the display of conspicuous coloration, as in the skunk; sometimes the emission of sound as in the rattlesnake; sometimes a combination of the two, as in the common porcupine and the large black scorpions of Africa and India. Such characters have been termed by Professor Poulton "aposematic." Neither of the above-mentioned animals is mimicked; but where two or more noxious animals, inhabiting the same district, resemble each other, both being aposematically or warningly coloured, the likeness is said to be "synaposematic." Synaposemasy is Müllerian mimicry. Finally, the likeness of an edible species to a warningly coloured inedible one in the same locality is termed "pseudaposematic," in allusion to the pretentiousness or falsity of the warning signal. Pseudaposemasy is Batesian mimicry.

An important phenomenon connected with insect mimicry is the convergence of several species in the same area towards a common type of coloration and shape, exhibited by one or more than one protected form. The resemblance shows various grades of completeness; and the convergent mimics may be themselves noxious, or edible and innocuous. In other words the insects entering into the combination may furnish instances of Batesian and of Müllerian mimicry. Very commonly different species of aculeate Hymenoptera, inhabiting the same district, form the centres of mimetic attraction for insects of various orders, so that a considerable percentage of the insect-fauna can be arranged in groups according to the pattern of the particular model the species have copied. Good illustrations of this law have been discovered by Guy Marshall in Mashonaland. He found on the same day on a bud of vetch, specimens of black ants (*Camponotus sericeus* and *C. cosmicus*), black ant-like Hemipterous insects (*Megapetus atratus*) and the ant-like Orthopteron (*Myrmecophana fallax*) (cf. *supra*). In this little coterie the ants are beyond question the models towards which the bug and the grasshopper have converged in appearance. Since many of the insects of the order Hemiptera are distasteful, the mimicry of the bug (*Megapetus*) is in this case probably Müllerian or synaposematic; the grasshopper (*Myrmecophana*), on the other hand, is probably edible and the mimicry is Batesian or pseudaposematic. This is a simple case consisting of a small number of component species. Others are more complex, numerous species being involved. In Mashonaland, for instance, a large number of genera and species of Hymenoptera belonging to the Apidae, Eumenidae, Sphegidae, Pompilidae, Scoliidae, Tiphiidae and Mutillidae, resemble each other in having black bodies and dark blue wings. The same style of coloration is found in Coleoptera of the families Cetoniidae and Cantharidae; in Diptera of the families Asilidae, Bombylidae, Tabanidae and Tachinidae; in Hemiptera of the family Reduviidae and in Lepidoptera of the family Zygaenidae. In this instance the Hymenoptera, of which the coloration is synaposematic, form together a composite model which the other insects have mimicked. Of the latter, the Lepidopteron (*Tascia homochroa*) is distasteful, as also are the beetles of the family Cantharidae (*e.g Lytta moesta*). Probably the bugs too (*e.g. Harpactor tristis*) are protected. The mimicry of these insects therefore is synaposematic; but some, at all events, of the flies like the Bombylid *Exoprosopa umbrosa*, probably form pseudaposematic elements in the group. Into another category Hymenoptera enter not as models but as mimics, the models being inedible Malacodermatous beetles mostly belonging to the genus *Lycus* and characterized by orange coloration set off by a large black patch upon the posterior end of the elytra and a smaller black spot upon the thorax. Towards this Lycoid centre have converged Coleoptera (beetles) of the sub-order Lamellicornia (Copridae), Phytophaga; Heteromera (Cantharidae) and Longicornia; Hemiptera of the families Pyrrhocoridae, Lygaeidae and Reduviidae; Lepidoptera of the families Arctiidae and Zygaenidae; Diptera of the family Asilidae; and lastly Hymenoptera of the families Braconidae, Pompilidae, Crabronidae and Eumenidae. With the exception of the Asilid fly and perhaps some of the Longicorn and Phytophagous beetles, which are probably protected Batesian mimics, all the other species constituting the above-mentioned assemblage are, it is believed, Müllerian or synaposematic mimics. In the three cases cited above, with the exception of the first, the synaposematic mimics are vastly in excess of the pseudaposematic; this appears to be the general rule elsewhere. Frequently the groups are composed solely of protected species, so far as is at present known; and sometimes solely, in all probability, of unprotected species with exception of course of the model. An example of the latter occurs in Singapore where the vicious red spinning-ant (*Oecophylla smaragdina*) is mimicked by the larva of a Noctuid moth and by spiders belonging to two distinct families, namely, *Saltiicus plataleoides* (Salticidae) and *Amyciaea forticeps* (Thomisidae), there being no reason to suppose that either the moth larva or the spiders are protected forms. Mimetic aggregations of species similar to those mentioned above have been found in other countries; but the instances cited are sufficient to show how widespread are the influences of mimicry and how profoundly it has modified the insect fauna of various parts of the world.

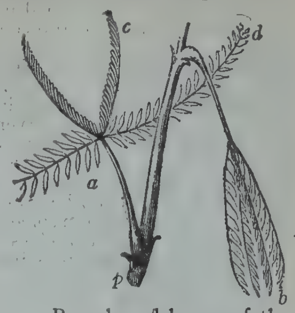
MIMNERMUS of Colophon, Greek elegiac poet, flourished about 630–600 B.C. His life fell in the troubled time when the Ionic cities of Asia Minor were struggling to maintain themselves against the rising power of the Lydian kings. One of the extant fragments of his poems refers to this struggle, and contrasts the present effeminacy of his countrymen with the bravery of those who had once defeated the Lydian king Gyges. But his most important poems were a set of elegies addressed to a flute-player named Nanno, collected in two books called after her name. Mimnermus was the first to make the elegiac verse the vehicle for love-poetry. He set his own poems to the music of the flute, and the poet Hipponax says that he used the melancholy νόμος κραδίης, "the fig-branch strain," said to be a peculiar melody, to the accompaniment of which two human purificatory victims were led out of Athens to be sacrificed during the festival of Thargelia (Hesychius, *s.v.*).

Edition of fragments in T. Bergk, *Poetae lyrici Graeci*; see also G. Vanzolini, *Mimnermo* (1883), a study of the poet, with notes and a metrical version of the fragments.

MIMOSA (so named from the movements of the leaves in many species which "mimic" animal sensibility), a genus of the natural order Leguminosae, which gives its name to the large sub-order *Mimoseae* (characterized by usually small regular flowers with valvate corolla), to which belongs also the nearly allied genus *Acacia*. They are distributed throughout almost all tropical and subtropical regions, the acacias preponderating in Australia and the true mimosas in America. The former are of considerable importance as sources of timber, gum and tannin, but the latter are of much less economic value, though a few, like the ṭalḥ (*M. ferruginea*) of Arabia and Central Africa, are important trees. Most are herbs or undershrubs, but some South American species are tall woody climbers. They are often prickly The roots of some Brazilian species are poisonous, and that of *M. pudica*, has irritating properties. The mimosas, however, owe their interest and their extensive cultivation, partly to the beauty of their usually bipinnate foliage, but still more to the remarkable development in some species of the sleep movements manifested to some extent by most of the pinnate Leguminosae, as well as many other (especially seedling) plants. In the so-called "sensitive plants" these movements not only take place under the influence of light and darkness, but can be easily excited by mechanical and other stimuli. When stimulated—say, at the axis of one of the secondary petioles—the leaflets move upwards on each side until they meet, the movement being propagated centripetally. It may then be communicated to the leaflets of the other secondary petioles, which close (the petioles, too, converging), and thence to the main petiole, which sinks rapidly downwards towards the stem, the bending taking place at the pulvinus (*p* in figure) or swollen base of the leafstalk. When shaken in any way, the leaves close and droop simultaneously, but if the agitation be continued, they reopen as if they had become accustomed to the shocks. The common sensitive plant of hothouses is *M. pudica*, a native of tropical America, but now naturalized in corresponding latitudes of Asia and Africa, but the hardly distinguishable *M. sensitiva* and others are also cultivated. Species of the closely allied genus *Schrankia* are known as sensitive-briar in the southern United States.



Branch and leaves of the sensitive plant (*Mimosa pudica*), showing the petiole in its erect state, *a*, and in its depressed state, *b*; also the leaflets closed (*c*), and the leaflets expanded (*d*); *p*, pulvinus.

MIMULUS, in botany, a genus (nat. order Scrophulariaceae), of showy, hardy or half-hardy, herbaceous, rarely shrubby plants, natives of the extra-tropical or mountainous parts of both old and new worlds excepting Europe, but chiefly American. The plants have opposite, undivided leaves, and axillary, generally solitary flowers with a two-lipped, gaping corolla. The herbaceous species thrive best in damp situations; the shrubby species, of which *M. glutinosus* (formerly called *Diplacus*) is best known, are adapted for pot culture in the greenhouse. *M. luteus*, the monkey-flower of gardens, has yellow flowers with two dark marks in the mouth of the corolla; *M. Langsdorfii*, an American species, has become naturalized by river-sides in many parts of Britain.

M. moschatus, musk, a native of north-western America, with small, nearly regular, yellow flowers, diffuse hairy stem and hairy scented leaves, is a well known and favourite perennial for pot culture and outside borders.

MINA, FRANCISCO ESPOZ Y (1781–1836) Spanish guerrillero leader and general, was born at Ydozin in Navarre on the 17th of June 1781. His father, Juan Esteban Espoz y Mina, and his mother Maria Teresa Hundain y Ardaiz, belonged to the class of yeomen. Mina remained working on the small family inheritance till 1808. When Napoleon endeavoured to seize Spain in that year he enlisted in the regiment of Doyle, and then passed to the guerrilla band commanded by his nephew Xavier Mina. When Xavier was captured by the French on the 21st of March 1810, seven men of the band elected to follow Francisco; and on the 1st of April of the same year the Junta of Aragon gave him the command of the guerrilleros of Navarre. His first act was to arrest and shoot at Estella, one Echevarria, who, under pretence of being a patriotic guerrillero, was in fact a brigand. The national government at Cadiz gave him rank, and by the 7th of September 1812, he had been promoted to be commander-in-chief in Upper Aragon, and on the left bank of the Ebro. In the interval he claimed that he had fought 143 actions big and little, had been repeatedly wounded with bullet, sword and lance, had taken 13 fortified posts, and 14,000 prisoners, and had never been surprised by the French. Though some maintain that he was not at his best as a leader in battle, as a strategist he was very successful, and he displayed great organizing capacity. The French authorities were compelled to allow him to levy customs dues on all goods imported into Spain, except contraband of war, which he would not allow to pass without fighting. The money thus obtained was used to pay his bands a regular salary. He was able to avoid levying excessive contributions on the country and to maintain discipline among his men, whom he had brought to a respectable state of efficiency in 1812. Mina claimed that he immobilized 26,000 French troops which would but for him have served with Marmont in the Salamanca campaign. In the campaign of 1813 and 1814 he served with distinction under the duke of Wellington. After the restoration of Ferdinand he fell into disfavour. On the 25th and 26th of September he attempted to bring about a rising at Pamplona in favour of the Liberal party, but failed, and went into exile. His political opinions were democratic and radical, and as a yeoman he disliked the hidalgos (nobles). The revolution of 1820 brought him back, and he served the Liberal party in Galicia, Leon and Catalonia. In the last district he made the only vigorous resistance to the French intervention in favour of Ferdinand VII. On the 1st of November 1823 he was compelled to capitulate, and the French allowed him to escape to England by sea. In 1830 he took part in an unsuccessful rising against Ferdinand. On the death of the king he was recalled to Spain, and the government of the regent Christina gave him the command against the Carlists in 1835, though they feared his Radicalism. By this time, years, exposure and wounds had undermined his health. He was also opposed to Thomas Zumalacarregui (*q.v.*), an old officer of his in the War of Independence, and an even greater master of irregular mountain warfare. His health compelled him to resign in April 1835, and his later command in Catalonia was only memorable for the part he took in forcing the regent to grant a constitution in August 1836. He died at Barcelona on the 24th of December 1836. Mina was a brave and honest man, who would have conducted the war against the French in 1810–12 with humanity if they had allowed him, but as they made a practice of shooting those of his men whom they took, he was compelled to retaliate. He finally forced the French to agree to an exchange of prisoners.

Authorities.—In 1825 Mina published *A Short Extract from the Life of General Mina*, in Spanish and English, in London. Mention is made of him in all histories of the affairs of Spain during the first third of the 19th century. His full Memoirs were published by his widow at Madrid in 1851–1852. (D. H.)

MINARET (from the Arabic *manārat*; *manar* or *minar* is Arabic for a lighthouse, a tower on which *nar*, fire, is lit), a lofty turret peculiar to Mahommedan architecture. The form is derived from that of the Pharos, the great lighthouse of Alexandria, in the top storey of which the Mahommedan conquerors in the 7th century placed a small praying chamber. The lighthouse form is perpetuated in the minarets which are found attached to all Mahommedan mosques, and probably had considerable influence on the evolution of the Christian church tower (see an exhaustive study in Hermann Thiersch, *Pharos Antike, Islam und Occident*, 1909). The minaret is always square from the base to the height of the wall of the mosque to which it is attached, and very often octangular above. The upper portion is divided into two or three stages, the wall of the upper storey being slightly set back behind the one below, so as to admit of a narrow balcony, from which the *azan*, or call to prayer, is chanted by the *muazzin* (*muezzin*, *moeḍḍin*). In order to give greater width to the balcony it is corbelled out with stalactitic vaulting. The balconies are surrounded with stone balustrades, and the upper storeys are richly decorated; the top storey being surmounted with a small bulbous dome. The earliest minaret known is that which was built by the caliph Walid (A.D. 705) in the mosque of Damascus, the next in date being the minaret of the mosque of Tulun, at Cairo (A.D. 879), with an external spiral flight of steps like the observatory towers in Assyrian architecture. This minaret as also the example of El Hakim (996), is raised on great square towers. The more remarkable of the other Cairene minarets are those of Imam esh-Shafi (1218), Muristan al Kalaun (1280), Hassan (1354), Barkuk (A.D. 1382) and Kait Bey (A.D. 1468). Of the same type are the two minarets added to the mosque of Damascus in the 15th century. In Persia the minarets are generally circular, with a single balcony at the top, corbelled out and covered over. In India, at Ghazni, there are no balconies, and the upper part of the tower tapers upwards; the same is noticeable at Delhi, where the minaret of Kutab is divided into six storeys with balconies at each level. In the well-known tomb of the Taj Mahal the four minarets are all built in white marble, in three storeys with balconies to each storey, and surmounted by open lanterns. The minarets of Constantinople are very lofty and wire-drawn, but contrast well with the domes of the mosques, which are of slight elevation as compared with those at Cairo.

MINAS [MINOÏDES] (*c.* 1790–1860), Greek scholar, was a native of Macedonia. During the Greek War of Independence he migrated to Paris, where he tried to enlist the sympathies of Europe on behalf of his countrymen and to promote the study of ancient and modern Greek. But his chief claim to recognition consists in his discovery of two important MSS. (amongst others) in the monastery of Mt Athos during his exploration of the libraries of Turkey and Asia, at the instance of M. Villemain, minister of public instruction in France. One of these contained the last part of a treatise on the *Refutation of all Heresies*, now generally admitted to be the work of Hippolytus (*q.v.*), the other the greater portion of the Fables of Babrius.

MINAS GERAES (*i.e.* "general mines"), popularly Minas, an inland state of Brazil, bounded N. by Goyaz and Bahia, E. by Bahia, Espirito Santo and Rio de Janeiro, S. by Rio de Janeiro and São Paulo, and W. by São Paulo, Matto Grosso and Goyaz. It is very irregular in outline and covers an area of 221,861 sq. m. upon the great Brazilian plateau. Among the Brazilian states it is fifth in size and first in population—3,184,099 in 1890, and 3,594,471 in 1900.

The surface of Minas Geraes is broken by mountain ranges and deeply eroded rivercourses, the latter forming fertile valleys shut in by partly barren uplands, or campos. The reckless destruction of forests along the watercourses also adds to the barren aspect of the country. The principal mountain ranges are the Serra da Mantiqueira on its southern frontier and its N. extension, the S. do Espinhaço, which runs parallel to the Serra do Mar, or coast-range, and separates the inland or campo region from a lower forested zone between the two ranges. Most of the wooded district south of the Mantiqueira belongs to the states of São Paulo and Rio de Janeiro, but east of the Espinhaço it belongs to Minas Geraes and extends eastward to the Serra das Aymores, on the frontier of Espirito Santo. This zone has an abundant rainfall, dense forests and a fertile soil. It is drained by the Doce, Mucury, Jequitinhonha and Pardo, which have their sources on the eastern slopes of the Espinhaço and cut their way through the Aymores to the sea. The tributaries of the Rio Doce cover the slopes of the Serra do Espinhaço for a distance north and south of about 200 m. The southern part of this region is well populated, and is covered with coffee and sugar plantations. On the western frontier a northern extension of the great central chain of Goyaz forms the water-parting between the drainage basins of the São Francisco and Tocantins, and is known at different points as the Serra do Paranan, Serra de São Domingos and Serra das Divisões. South-east of this chain, between the headwaters of the Paraná and São Francisco, are the Serra da Canastra and Serra da Matta da Corde, an irregular chain of moderate elevation running north and south. The highest elevations in the state, so far as known, are Itatiaya (8898 ft.) in the Serra da Mantiqueira, and Caraça (6414 ft.), near Ouro Preto, in the Serra do Espinhaço. The hydrography of the campo region of Minas Geraes is extremely complicated. The Mantiqueira-Espinhaço chain shuts out the streams flowing directly east to the Atlantic, and the boundary ranges on the west shut out the streams that flow into the Tocantins, though their sources are on the actual threshold of the state. Between these two mountain chains the head streams of the Paraná and São Francisco are intermingled—the one flowing inland and southward to the great La Plata estuary, the other northward and eastward across the arid highlands of Brazil to the Atlantic coast in 10° 30′ S. lat. Less than 100 m. from the city of Rio de Janeiro and about 60 m. from the coast is the source of the Rio Grande, the larger of the two rivers that form the Paraná. It rises near the peak of Itatiaya, on the northern slopes of the Mantiqueira, and flows north-west and west across the Minas plateau, receiving several large tributaries from the south. North and parallel with its course is a low watershed, which separates its drainage basin both from that of the São Francisco and from that of the Parnahyba, the northern confluent of the Paraná. The latter rises on the western slopes of the Serra da Matta da Corde, and one of its northern tributaries has its source in a "knot" of the Serra dos Pyreneos, from which streams flow eastward to the São Francisco and northward to the Tocantins. The central and greater part of the state, however, is included in the drainage basin of the upper São Francisco. Its source is in the Serra da Canastra, and its general course across the state is north by east, during which it receives the Paracatú, Urucuia, Pardo and Carinhanha from the west and the Verde Grande and das Velhas from the east. Part of these rivers are navigable for small steamers, and the São Francisco must some day be of great importance in the development of Central Brazil. All these rivers of the Brazilian plateau are interrupted by falls and rapids. The climate of Minas Geraes is characterized by high sun temperatures and cool nights, the latter often dropping below the freezing point on the higher campos. The mean annual temperature is about 85° in the São Francisco valley, 77° on the campos of the S.E., and 70° on the campos of the W. The year is divided into two seasons—wet and dry—the former lasting from November to May. This division is not so clearly marked in the south, especially in the "matta" (forest) regions, where the rainfall ranges from 59 to 65 in. There is much malaria in the wooded districts of the east and on the higher campos, where the daily extremes of temperature are great, lung and bronchial diseases are common. Some of the high plains, however, as at Barbacena, serve as health resorts for the coast districts.

Minas Geraes is a mining state, though the mining industry has lost much of its importance through the decline in the output of gold and diamonds. Gold is widely diffused, and abandoned "washings" all over the state show how general the industry was at one time. There were in 1908 five deep mines worked by English companies and one by a French company. One of these, the Morro Velho mine, belonging to an English company, is not only the deepest gold-mine in existence (over 2000 ft.), but it has been worked since 1725, and since 1835 by its present owners. Silver is not mined by itself, but is found in combination with gold. In 1908 a rich goldfield was discovered in the northern part of the state, 5 m. from Montes Claros, in the valley of the Verde Grande River, and attracted large numbers of miners. There are many rich deposits of iron ores in the state, but they only produce a small quantity of charcoal iron for local consumption. Manganese ore is mined for export, and bismuth is reported to have been discovered. Minas Geraes is most widely known for its diamonds, which are found in widely separated parts of the state. The largest and most productive field is that of Diamantina (*q.v.*) on the head-waters of the Jequitinhonha River, where diamonds were discovered about 1725, and where the celebrated "diamond reservation"—an oval-shaped territory 8 leagues wide by 16 leagues long (Mawe), with Tejuco, now Diamantina, very nearly in the centre—was established in 1730. The mines became crown property, gold-mining was forbidden, and no one was permitted to enter the reservation without a licence. The state monopoly was abolished in 1832, and mining has since been carried on by private enterprise. John Mawe estimates that the annual product was 1000 oz. during the first twenty years, and Castelnau estimates the value of the total output down to 1849 at 300,000,000 fr. No estimate can be made of the contraband, which must have been large. A great decline in the output occurred during the last half of the 19th century; but a new field was discovered in 1908 at Abbadia dos Dourados, in the western part of the state. Other valuable stones, the topaz, chrysolite, aquamarine amethyst and tourmaline are found.

Agriculture and grazing have become the main dependence of the population—the former in the lower, forested region of the south-east, where coffee and sugar-cane are the principal products, and the latter on the higher campos and river valleys, and on the mountain slopes, where large herds of cattle are to be found, and milk, butter and cheese are produced. The shipping of fresh milk to Rio de Janeiro and butter-making are comparatively new industries. The river valleys of the campo region are also cultivated to some extent. Among the general products are Indian corn, tobacco, mandioca, beans, pork and cotton. Wheat has been produced in some localities, but not on a paying basis, and experiments have also been made with tea. There is a large variety of fruits, and the cultivation of grapes for wine-making is developing into a profitable industry. Railway communication with Minas Geraes includes the following lines: the Central do Brazil (formerly known as the Dom Pedro II.), which starts from Rio de Janeiro and penetrates nearly to Pirapora (its objective point), at the head of navigation of the São Francisco River, with branches into neighbouring districts; the Leopoldina, from Rio de Janeiro into the forested region of eastern Minas; the Minas and Rio, from Cruzeiro, on the São Paulo branch of the Central do Brazil, into southern Minas; the Mogyana, from Campinas, São Paulo, and runs to Uberaba in western Minas, and is intended to cross into Goyas; and the Bahia & Minas, from the port of Caravellas, in southern Bahia, which runs a short distance into Minas Geraes, and is planned to extend to Philadelphia and beyond. Another line from the port of Victoria, Espirito Santo, northward to Diamantina, Minas Geraes, was under construction in 1908. River transport has some local value on the upper São Francisco and its larger tributaries, and this will be greatly increased when the Central do Brazil railway reaches the head of navigation on that river.

The population of Minas Geraes is chiefly of Portuguese origin, which has been constantly strengthened by immigrants from the mother country. A considerable admixture from other nationalities has resulted from the influx of mining adventurers, and some German colonies have been established in the state. The negro population is large, and there is a still larger contingent of mixed races. The capital is Bello Horizonte (*q.v.*), or Cidade de Minas; other important cities and towns are: the former capital, Ouro Preto, Barbacena, Diamantina, Baependy (pop. 22,817 in 1890), on the head-waters of the Rio Verde, the centre of a rich tobacco-producing district; Curvello (8071), north of Sabará in the Rio das Velhas Valley, the centre of a cotton-growing district and cotton manufactures; Entre Rios (7681), in the coffee district of south-east Minas; Januaria (5888), a river port of the São Francisco in northern Minas; Juiz de Fóra; Marianna (4751), an episcopal town east of Ouro Preto, Mar de Hespanha (18,712), the centre of a productive and populous agricultural municipality of south-east Minas; Paracatú (21,418), an important commercial centre of western Minas near the Goyaz frontier; Queluz (12,600), on the Central do Brazil railway; Congonhas do Campo (10,902), in the municipality of Queluz, celebrated for its miracle-working image, its great church and chapels, and the pilgrimages to its shrine; Sabará (4959), a railway junction on the Central do Brazil, and port on the Rio das Velhas; Congonhas de Sabará (14,066), in the municipality of Sabará, where the celebrated Morro Velho gold-mine is situated; São João d' El-Rei (15,820) an important commercial mining and pastoral centre, near the Rio das Mortes, connected with the Central do Brazil railway by a branch called the Oeste de Minas; and Uberaba (12,231), a commercial town of the western campos of Minas, connected with São Paulo by the Mogyana and São Paulo railways.

Minas Geraes was first explored by Fernando Dias Paes Leme between 1664 and 1677, though he was not the first European to penetrate it. The discovery of gold in 1692–1695 by bands of adventurers from the São Paulo settlements, led to every occupation and profession being abandoned in the mad rush for the new mines. Minas Geraes at first formed part of the capitania of São Paulo, but in 1720 it became a separate government and was brought more directly under the Portuguese crown. The arbitrary restrictions imposed upon the colonists aroused dissatisfaction among them and eventually led to conspiracy in 1789, inspired by a fear that the Portuguese government was about to enforce the collection of its "fifths" of the mining output, which had largely fallen into arrears. Among the conspirators was one José Alves Maciel, who had just returned from France where he had met Thomas Jefferson and had become infected with French revolutionary ideas. A number of residents became involved, among them the poet Thomaz Antonio Gonzaga. Reckless talk in public places led to the arrest of the conspirators. Only one was executed, a poor, uneducated subaltern militia officer Joaquim José da Silva Xavier, nicknamed *O Tiradentes* (the Tooth-puller), the others being imprisoned or banished. Tiradentes has since been glorified as the pro-martyr of Brazilian independence. In 1822 Minas became a province of the empire created by Dom Pedro I., though a revolutionary outbreak had occurred in Ouro Preto the year before. In 1842 a long series of quarrels in Rio de Janeiro culminated in a revolution in Minas Geraes and São Paulo, which was suppressed at Santa Luzía, Minas Geraes, on the 20th of August of that year. The abolition of slavery in 1888 caused much discontent among the planters and in the following year Minas Geraes promptly adhered to the declaration of the republic in Rio de Janeiro.

MINBAR, or MIMBAR, a term in Mahommedan architecture for the pulpit in a mosque from which the Friday or Mahommedan Sabbath sermon is given (see PULPIT).

MINBU, a district and division of Upper Burma. The district has an area of 3299 sq. m., and a population (1901) of 233,377, showing an increase of 8% in the decade and a density of 71 inhabitants to the sq. m. The district may be said to consist of low plain-land towards the Irrawaddy, and of undulating country inland rising higher and higher westwards towards the Arakan hills. Between the plain and the Arakan Yoma range is a distinct line of hills running north and south, and usually called the Nwa-Madaung hills. The submontane valleys are largely cultivated, but are deadly except to those born in them. The chief streams besides the Irrawaddy are the Môn, the Maw, and the Salin, which are largely used for irrigation. At Minbu town the Irrawaddy is 3 miles wide, with many islands and sandbanks. There are considerable fisheries along the Irrawaddy and on the Paunglin lake, which is a lagoon fed from the Irrawaddy. The rights are sold yearly by public auction, and realize an average of £1000. Oil has been discovered near the mud volcanoes of Minbu, but it seems to lie at too great a depth to be profitably worked.

There is a large area of reserved forest in the district. The chief crops raised are rice, gram, millet, beans, peas, sesamum and tobacco. The betel-vine is largely cultivated along the Môn River. The district, which was in a chronically disturbed state before the annexation, was not reduced till two years afterwards, many officers losing their lives, among them Phayre, the first deputy-commissioner. The annual rainfall varies greatly over the district. It is very considerable on and under the Arakan Yomas, and very slight towards the Irrawaddy. The thermometer rises to over 100° in the hot months, and the mean of minimum in December is about 49°. MINBU, the district headquarters, stands on the Irrawaddy. It had a population of 5780 in 1901. The river steamers in the dry season can come no nearer than two miles to the south of the town.

The division includes the districts of Thayetmyo, Pakôkku, Minbu and Magwe. It has a total area of 17,172 sq. m. and a population (1901), of 1,076,280, showing an increase of 8% in the decade and giving a density of 63 inhabitants to the square mile. It bestrides the Irrawaddy. (J. G. Sc.)

MINCHINHAMPTON, a town in the Stroud parliamentary division of Gloucestershire, England, 4 m. S.E. of Stroud. Pop. (1901), 3737. It lies high on a slope of the Cotswold Hills; Minchinhampton Common being a fine open upland. The church of Holy Trinity, largely reconstructed, contains many brasses and memorials. The manufacture of woollen cloth is the long-established staple of Minchinhampton. Prehistoric remains have been discovered on the common, and earthworks are also seen; while the name of Woeful Dane Bottom, a neighbouring valley, perhaps indicates the scene of a defeat of the Danes (*c.* 918).

MINDEN, a town of Germany, in the Prussian province of Westphalia, 44 m. by rail to the W.S.W. of Hanover, on the left bank of the Weser, which is spanned by two bridges. Pop. (1905), 25,428. The older parts of the town retain their narrow and crooked streets. The cathedral tower dating from the 11th century, illustrates the first step in the growth of the Gothic spire in Germany. The nave was erected at the end of the 13th century, and the choir in 1377–1379. Among the chief edifices are the old church of St Martin; the town hall, with a Gothic façade; the law courts and the government offices, constructed, like many of the other buildings, of a peculiar veined brown sandstone found in the district. The town has a statue of Frederick William I., the great elector of Brandenburg. Minden contains a gymnasium and several hospitals, besides other charitable institutions. Its industries include linen and cotton weaving, dyeing, calico printing, brewing, ship-building and the manufacture of tobacco, glass, soap, chocolate, leather, lamps, chicory and chemicals. There is also some activity in the building of small craft.

Minden (Mindun, Mindo), apparently a trading place of some importance in the time of Charlemagne, was made the seat of a bishop by that monarch, and subsequently became a flourishing member of the Hanseatic League. In the 13th century it was surrounded with walls. Punished by military occupation and a fine for its reception of the Reformation, Minden underwent similar trials in the Thirty Years' War. In 1648 the bishopric was converted into a secular principality under the elector of Brandenburg. From 1807 to 1814 Minden was included in the kingdom of Westphalia, and in the latter year it passed to Prussia. In 1816 the fortifications, which had been razed by Frederick the Great after the Seven Years' War, were restored and strengthened, and as a fortress of the second rank it remained the chief military place of Westphalia down to 1873, when the works were finally demolished. About 3 m. to the south of Minden is the so-called "Porta Westfalica," a narrow defile by which the Weser quits the mountains. The bishopric of Minden embraced an area of about 400 sq. m. and had about 70,000 inhabitants.

The battle of Minden was fought on the 1st of August 1759 between the Anglo-Allied army commanded by duke Ferdinand of Brunswick and the French under Marshal Coutades, the latter being defeated. The most brilliant episode of the battle was the entire defeat of the French cavalry by the British infantry (with whom there were some Hanoverian troops), but Minden, though it is one of the brightest days in the history of the British army, has its dark side also, for the British cavalry commander Lord George Sackville (see SACKVILLE, VISCOUNT) refused to obey the order to advance, several times sent by Duke Ferdinand, and thereby robbed the victory of the decisive results which were to be expected from the success of the infantry. For an account of the battle and of the campaign of which it is the centre, see SEVEN YEARS' WAR.

See Stoy, *Kurzer Abriss der Geschichte Mindens* (Minden, 1879); Bölsche, *Skizzen aus Mindens Vergangenheit* (Minden, 1897); Holscher, *Beschreibung des vormaligen Bistumes Minden* (Münster, 1877).

MINEHEAD, a market town and seaside resort in the Wellington parliamentary division of Somersetshire, England, 188 m. W. by S. of London by the Great Western railway. Pop. of urban district (1901), 2511. The town has three parts: the Upper, built on the sides of a lofty foreland known as North Hill; the Lower; and the Quay Town, with many ancient houses, stretching for about a mile beside the harbour. It is much visited for the sake of its mild climate, the grand cliffs, moors and hills of the neighbourhood, and the beach, admirably suited for bathing. St Michael's, the parish church, has a striking Perpendicular tower, an arch of carved oak dividing its nave and chancel, a magnificent rood-loft, and a 13th-century monument doubtfully described as the tomb of Bracton, the famous lawyer, whose birthplace, according to local tradition, was Bratton Court in the vicinity. Coaches for Porlock and Lynton start from the town.

There is no evidence of the existence of Minehead (*Mannheve*, *Manehafd*, *Mynneheved*) in Roman or Saxon times. The town owed its origin and growth to its position on the shores of the Bristol Channel, and its good harbour developed an oversea trade with Bristol, South Wales and the Irish ports. The De Mohun family were overlords of the town from 1086 to the 14th century, when they were followed by the Luttrells, who are the present owners. It is possible that Minehead had a corporate existence during the 15th century, as certain documents executed by the portreeve and burgesses at that date are preserved, but no record of the grant of a charter has been found. A charter of incorporation given by Elizabeth in 1558 vested the government in a portreeve, a steward and twelve burgesses, the continuance of the corporation being subject to the port and harbour being kept in repair. This condition being unfulfilled, the charter lapsed in the reign of James I., and an attempt to obtain its renewal in the 18th century failed. The corporation was replaced by two constables chosen annually in the court leet of the manor until 1894, when an urban district council was appointed. The borough returned two members to parliament from 1558 until disfranchised by the Reform Act of 1832. A weekly market on Tuesdays and a fair (Sept. 29 to Oct. 2) were held by the lord of the manor from the 15th century, but the date of the grant has not been found. In 1465 a second annual fair on the 1st of May was granted by Edward IV., which is still held on the Wednesday in Whitsun week. The other fair has been discontinued, and the market day has been changed to Wednesday. During the 16th, 17th and 18th centuries Minehead had a considerable coastwise trade in wool, grain and wine, but began to decline owing to the migration of the woollen industry to the north of England, and to the decay of the herring fishery. A renewal of prosperity began when it acquired a reputation as a watering-place.

See *Victoria County History: Somerset*; F. Handcock, *Parish and Borough of Minehead* (1903).

MINEO, a town of the province of Catania, Sicily, 34 m. S.W. of Catania by rail. Pop. (1901), 9828. It occupies the site of the ancient *Menaenum*, founded by Ducetius in 459 B.C. There is some doubt as to whether this town was also the birthplace of Ducetius, owing to confusions in nomenclature (see E. A. Freeman, *History of Sicily*, ii. 361). Remains of ancient fortifications still exist, though it seems uncertain whether they are of Greek or of Byzantine origin (*Notizie degli Scavi*, 1899, p. 70). Four miles to the north is the Lacus Palicorum, a small lake in a crater, which still sends up carbonic acid gas. By it was the temple of the Palici, twin Sicel gods, the most holy place in Sicily, where an oath taken was especially binding, and an inviolable asylum for fugitive slaves. There is now nothing to suggest twin deities; in ancient times there were probably two craters, whereas now there is only one. It was here that Ducetius, a few years later, founded a new seat for his power, the city of Palica.

MINERAL DEPOSITS. The subject of mining (*q.v.*) can only be properly understood after the general features of mineral deposits have been elucidated. In this article deposits of all kinds of useful minerals are included, whether they are metalliferous or earthy. In general practice it is customary to treat the former under the name "ore-deposits" and the latter as the "non-metallics." This is warranted because in a large degree different geological problems are presented and different methods of mining are pursued. Nevertheless there are other important similar or common features and they may be classed together without great disadvantage.

Ore.

The word "ore" is used in several meanings, each of which depends for its special significance upon the connexion. In purely scientific applications "ore" implies simply a metalliferous mineral, and in this sense it appears in works on mineralogy and petrology. In former years and in connexion with practical mining an ore was defined as a compound of metal or of metals with one or more non-metallic elements, called mineralizers, of which oxygen and sulphur were the chief. The ore must, in addition, be sufficiently rich to be mined at a profit. Native metals not being compounds were not considered ores. The product of the copper mines on Keweenaw Point, Lake Superior, was, and to a great extent is still, called copper rock rather than copper ore, and native gold in quartz is often described as gold quartz rather than gold ore, but these restrictions are gradually disappearing. An ore may therefore be defined as a metalliferous mineral or aggregate of metalliferous minerals mingled with a greater or less amount of barren materials called the "gangue," and yet rich enough to be mined at a profit. When not proved to be sufficiently rich to be remunerative, the aggregate is called "mineral." The "mineral" of to-day may be changed by the advent of a railway or the rise in the price of metal into the "ore" of to-morrow. The question has repeatedly appeared in litigation involving contracts or property rights.

Since the greater number of the ores are believed to have been precipitated from aqueous solution, or to have been otherwise formed through the agency of water, the term "ore-deposit" has resulted; and inasmuch as nearly all the other useful minerals owe their origin to the same agent, the term "mineral deposit" is equally well justified. A few, however, have been produced in a different way, such as certain iron ores of igneous origin; certain igneous rocks used for building stone, as in the case of granite; and the accumulations of vegetable material in coal beds. These latter, the igneous masses and the vegetable accumulations, being placed in two divisions by themselves, we may group the larger number into two main classes, depending on their precipitation from solution or from suspension. In the case of solution we will further subdivide on the place, and therefore in large part on the cause, of precipitation, since these are the questions chiefly involved in actual development.

Especially in connexion with ore-deposits widening experience has modified the older conceptions of relative values in the several types. In the early days of geology, Cornwall and Saxony were the two regions where the most active and influential students of ore-deposits were trained and where the principal books relating to mining originated. The pronounced and characteristic fissure veins of England and Germany became the standards to which the phenomena met elsewhere were referred, and by means of which they were described. This particular form, the fissure vein along a fault, assumed a predominating importance, both in the thought and in the literature of the day. Widening experience, however, especially in the Cordilleran region of North America, in the Andes of South America, in Australia and in South Africa, has brought other types into equally great and deserved prominence. Comprehensive treatment to-day therefore departs somewhat from earlier standards.

Occurrence.

As far as analyses and estimates permit, the common useful metals occur in the earth's crust in approximately the following percentages:—

1. Aluminium	8·13	7. Copper .	0·0000x
2. Iron . .	4·71	8. Lead .	0·0000x
3. Manganese	0·07	9. Zinc . .	0·0000x
4. Nickel . .	0·01	10. Silver . .	0·000000x
5. Cobalt . .	0·0005	11. Gold . .	0·0000000x
6. Tin . .	0·000x–·0000x	12. Platinum	0·00000000x

By the letter x is meant some undetermined digit in the corresponding place of decimals. Apart from aluminium, iron, manganese and nickel, the figures show how small is the contribution made by even the commoner metals to that portion of the mass of the globe which is open to observation and investigation.

As compared with the earth's crust at large certain of the metals are known to be locally present in favourable, usually igneous, rocks in richer amounts, according to the following determinations which have been made upon large samples of carefully selected materials. Copper, 0·009%; lead, 0·0011–0·008; zinc, 0·0048–0·009; silver, 0·00007–0·00016; gold, 0·00002–0·00004. Iron and aluminium seldom fail, and vary from 1 to 2% as a minimum, up to 25% as a maximum.

In order that the several metals may constitute ores, their percentages must be the following—the percentages of each vary with favourable or unfavourable conditions at the mine, and can therefore be expressed only in a general way; ores favourable to milling and concentration may go below these limits, and the mingling of two metals of which one facilitates the extraction of the other may also reduce the percentages:—

Aluminium	30	Nickel	2–5
Copper	2–10	Platinum	0·00005
Gold	0·003–·00016	Silver	0·03–0·16
Iron	35–65	Tin	1·5–3
Lead	2–25	Zinc	5–25
Manganese	40–50		

Cobalt is a by-product in the metallurgy of nickel and is usually in much inferior amount to the latter.

When we compare the first and second tabulations with the third it is at once apparent that with the possible although only occasional exception of iron the production of an ore-body from the normal rocks which constitute the outer mass of the earth requires the local concentration of each of the metals by one or several geological processes, and to a degree that is only occasionally developed in the ordinary course of nature. It is, therefore, an instance of somewhat exceptionally good fortune when one is discovered, and it is only the part of ordinary prudence to develop and utilize it as one would treat a resource which is limited and subject to exhaustion.

Classes of Mineral.

The minerals which constitute ore-bodies are divided into two great classes: the *ores proper*, which contain the metals; and the *barren minerals* or *gangue*, which reduce the yield.

The ores are generally and naturally subdivided into two groups: first, the sulphides and related compounds containing arsenic, antimony, tellurium and selenium; and, second, the oxidized compounds embracing oxides, carbonates, sulphates, silicates, phosphates, arsenates, chromates, &c. With the oxides are placed, because of related geological occurrence, a few rare compounds with chlorine, bromine and iodine into which silver more than any other metal enters, and to the same group we may add a few metals which occur in the native state. Iron, manganese, aluminium and tin differ from the rest of the metals in their original occurrence in the oxidized form, whereas the others with the exception of gold, platinum, and possibly copper, in their first precipitation in ore-bodies are in the form of sulphides or related compounds. Only by subsequent changes, characteristic of the upper parts of the deposits, do they pass by oxidation into the minerals of the second group.

With regard to the nature and source of the water which serves to gather up the widely disseminated metals and concentrate them in ore-bodies two contrasted views are now current, not necessarily antagonistic but applied in different degrees by different observers. The older view attributes the water primarily to the rainfall, and therefore it is called meteoric water. After falling upon the surface the meteoric water divides into three parts. The first, and smallest, evaporates; the second, the largest portion, joins the surface drainage and is called the run-off; while the third, intermediate in amount, sinks into the ground and mingles with the ground-waters. The ground-waters rise in springs, usually fed from no great depth, and themselves pass into the surface drainage after a small subterranean journey. While as a rule the ground-water level is fairly definite, yet it sometimes displays even in the same mining district great irregularity.
